This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF USEFUL KNOWLEDGE.

PERU is a country in South America, situated between 3° 30′ and 21° 28′ S. lat., and between 65° and 81° 20′ W. long. On the west it is washed by the Pacific; and on the south and south-east it borders on Bolivia. The boundary-line between these states, at the most southern point of Peru, is formed by the small river Loa (21° 28′ S. lat.): it follows the course of this river for several miles, when it turns eastward till it reaches the western edge of the Andes. It follows this edge northward to the mountain-pass of Gualillas (17° 50′ S. lat.), whence it runs northward across the plain of the lake of Titicaca to the southern extremity of that lake. It traverses the lake in a northern direction, which it preserves till it reaches the eastern chain of the Bolivian Andes, near 15° S. lat. It follows this chain for some distance, and then runs along the lateral range which branches off in an east-north-east direction between the river Tuche, an affluent of the Beni, and some rivers which are supposed to fall into the Purus. From the mouth of the river Tuche, the boundary-line between Peru and Bolivia runs along the Rio Beni to its junction with the Guaporé, by which the river Madera is formed. At this point commences the boundary-line between Peru and Brazil. This line follows the Madera river to 9° 30′ S. lat.: it stretches westward along this parallel to the river Yavari, the course of which river, up to its junction with the Amazonas, forms the remainder of the boundary between Peru and Brazil. The Amazonas is the boundary between Peru and Ecuador, from its junction with the Yavari to the town of S. Juan de Brancamoros, south of which place the river Chinchupe falls into the Amazonas. The Chinchupe separates both countries as far as its source, from which the dividing line passes over the Andes to the Rio Tumbez, which falls into the Gulf of Guayaquil, in 3° 30′ S. lat.

The length of this country from south to north, along the meridian of 70°, is above 1150 miles, but its width varies greatly. South of 17° S. lat. it hardly exceeds 30 miles, whilst near 10° S. lat. it is more than 650 miles wide. Its area, according to a rough estimate, considerably exceeds 500,000 square miles, being about two and a half times the extent of France.

Coast and Harbours.—The coast-line is about 1500 miles in length. In an extent of 1200 miles this coast forms only three straight lines, which meet at obtuse angles, and are not interrupted by any large bays. The most southern line runs south and north, the central line runs nearly south-east and north-west, and the northern line runs north-north-west. The most northern and most projecting portion of the coast is broken by bays and by headlands.

The southern coast-line, which runs south and north, extends from the mouth of the river Loa (21° 28′ S. lat.) to the harbour of Arica (18° 28′ S. lat.), a distance of 210 miles. The whole of this line consists of rocky cliffs, rarely low, and occasionally several hundred feet high. In a few spots a sandy beach lies between the cliffs and the sea. The projecting points seldom extend a mile from the mainland, and in no case more than two. They also form right angles with the coast, and as they occur only at distances of 10, 15, or 20 miles, they afford no shelter to vessels. A few small rocks lie off the coast, but they are low and too small to protect vessels which anchor between them and the shores. The soundings are irregular. Boats cannot land on these shores, as they are exposed to a very heavy swell from the Pacific, forming a dangerous surf, which can only be passed in favourable weather by boats. Landing in most places can only be effected by *balsas*. In all this extent of coast, fresh water can only be got at three places, the rivers Loa and Pisagua, and at Arica. The water of the river Loa is extremely bad. The water of the Rio Pisagua is good, but the river is dry nine months in the year, and the water obtained from the wells is bad. At Arica the water is excellent. The only harbour is that of Iquique, which is formed by a low island, the largest that occurs along this coast. Between it and the town is good anchorage in eleven fathoms. The harbour of Arica, which lies at the northern extremity of this coast-line, is also formed by a low island, called Huans, on the northern side of which there is good anchorage. A mole runs out into the sea, which enables boats to lie quietly while loading or discharging.

From Arica (18° 28′ S. lat.) to Point Carreta (14° 10′), a distance of more than 460 miles, the coast lies east-south-east and west-north-west. Where the cliffs come close to the sea, they rise from 50 to 300 feet above it, and the waves in some places break with great violence along the shore. Even the sandy beach is frequently interrupted by low projecting cliffs, but the soundings are in general regular. The projecting points are usually too short and too far from one another to form safe anchorages and to break the swell of the sea. Towards Point Carreta a few inlets occur, which form good harbours, though even here the landing in boats is generally difficult and sometimes impracticable. Fresh water is much more abundant, and may be got in several places. The first harbour which occurs, after leaving Arica, is that of Islay, the port of Arequipa. Cove Mollendo formerly served for that purpose, but it has so changed, that at present it only admits boats, or very small coasting vessels. Port Islay is formed by a few straggling islands which lie off Point Islay, and is capable of containing twenty or twenty-five vessels. The anchorage is good, but the landing extremely difficult, and at the full of the moon it is sometimes impracticable for several days. Point Lomas, the port of Acari, lies farther west, and is an open roadstead, but it has good anchorage in from five to fifteen fathoms, and tolerable landing. Some distance farther west there are two good harbours, S. Juan and S. Nicolas, with excellent anchorage and tolerable landing; but the country about them is sterile and uninhabited. Farther west is the Bay of Independencia, which lies between Cape Quemada and Cape Carreta, and is protected towards the sea by two islands, Santa Rosa and Santa Vieja, of which the latter rises to a considerable elevation. It extends 15 miles from south-east to north-west, and is about 3½ miles broad. There is anchorage in all parts of this spacious bay, the bottom being quite regular in about 20 fathoms. It may be entered from the south by the Strait of Serrate, between the island of Santa Rosa and Cape Quemada, which is three-quarters of a mile wide, or by the wide opening at the north-western extremity, which is called Dardo, and is five miles across between the island of Vieja and Cape Carreta. As the country surrounding this bay is very thinly inhabited, it is rarely visited by vessels.

The coast from Cape Carreta (14° 10′ S. lat.) to the roadstead of Lambayeque (6° 46′ S. lat.), a distance of about

620 miles, runs north-north-west, and exhibits a much greater portion of low sandy beach than is found farther south. A high ground invariably appears at the back of the low shore, in some places rising with a steep and in others with a gentle declivity. In a few places the high ground is six miles from the sea. Where the coast is high the rocks are frequently low, but in several places they rise to 100 or 300 feet. The projecting headlands are not numerous, and being short, and at right angles to the coast, they do not afford safe anchorage. Towards the south-eastern extremity are some islands, and between 7° and 10° S. lat. some inlets which are larger than commonly occur on this part of Peru, and good anchorage is found in them. The most southern of these harbours is the Bay of Pisco, which is between the mainland and a row of islands extending along the coast. The most southern of these islands, that of Gallan, is 2½ miles long, 1 mile wide, and of considerable elevation. North of it are the Ballista Islands, and north of them the Chinca Islands, both clusters of low rocks. The sea about these islands is deep, and the Bay of Pisco may be entered safely by all the passages thus formed. The most southern passage, which is between the island of Gallan and Point Paracca, is generally used; it is called the Boqueron of Pisco. Within the bay there is good anchorage in 12 fathoms. This bay is much visited by vessels, as the surrounding country is rather fertile, and the commerce of the town of Pisco is considerable.

Opposite the town of Cerro Azul there is only an open roadstead, with bad anchorage, and a heavy surf constantly breaking on the shore. The bay of Callao is between the coast and the island of S. Lorenzo, which is four miles and a half long from south-east to north-west, and a mile wide: its highest part is 1050 feet above the sea-level. The bay, which is extensive and commodious, has good anchorage; it is usually entered from the north round Cape Lorenzo, the northern extremity of the island, but it may also be entered by the Boqueron, a strait between Cape Callao and the southern extremity of the island. Salinas Bay, on the north of Salinas Head, which extends five miles into the sea from south to north, is of large dimensions, and affords good anchorage, but it is seldom visited. The bay of Sapé, to the north of Cape Thomas, is small, but as it is contiguous to a fertile district, it is much visited by coasters. The port of Guarmey, north of Point Legarto, is also small, but it contains good anchorage in three and a half to ten fathoms, on a fine sandy bottom. Firewood is abundant in the neighbourhood, and is exported. Between 9° and 10° S. lat. there are four comparatively good harbours, Casma, Samanco, or Huambacho, Ferrol, and Santa. That of Samanco is the largest port north of Callao, being six miles long from south-east to north-west, and four miles wide. The entrance is two miles wide. Port Ferrol is nearly equal in size, and entirely free from the swell of the ocean. Both harbours are much visited by coasters, as the adjacent country is fertile and well cultivated. There is no harbour farther north. Opposite the towns of Truxillo and Lambayeque there are only open roadsteads with bad anchorage.

North of the roadstead of Lambayeque, and between it and the Bay of Guayaquil, a huge promontory runs out into the sea. At its base, between Lambayeque and Point Malpelo (3° 30′ S. lat.) it is 220 miles wide, and its coast-line exceeds 300 miles. Between Point Aguja and Cape Blanco, the most projecting part of this promontory, the shores are rocky and steep, and rise to a considerable elevation; but near the roadstead of Lambayeque and on the Gulf of Guayaquil the shores are sandy and partially covered with brushwood. In this part there are two indentations, which form two tolerably deep but open bays. The southern is the Bay of Sechura, which is six miles deep, and at its entrance, between Cape Pisura and the Little Lobos Island of Payta, 12 miles wide. It is open to the swell of the sea, and is only navigated by the Indians in balsas. The Bay of Payta, which is farther north, is of smaller dimensions, but it is the best harbour on the coast of Peru, and is more visited by foreign vessels than any other harbour except Callao.

As the heavy surf occasioned by the swell of the Pacific renders landing with boats always dangerous, and often impracticable, *balsas* are used along this coast. These balsas differ in materials and form on the different parts of the coast. In Chile and the southern coast of Peru the balsa is a kind of sea-balloon, consisting of seal-skins made air-tight, and inflated like a bladder: they are so light that they float over the heaviest surf without danger. Two of these bladders are fastened together, and a sort of platform made of cane is fixed on them. These balsas hold from two to three persons. The balsa of the northern coast of Peru is a raft consisting of nine logs of the cabbage-palm secured together by lashings, with a platform raised about two feet, on which the goods are placed. They are employed for coasting along the shore, and have a lug sail, which is most used in landing. The wind being along the shore enables them to run through the surf and on the beach with ease and safety. At Lambayeque, where the surf is very heavy, a kind of balsa is used called *caballito:* it consists of bundles of reeds fastened together and turned up at the bow. Being very light, it is thrown on the top of the surf upon the beach, and the fishermen who use them jump off and carry them on their shoulders to their huts. It seems that each bay or road has its peculiar balsa.

Surface, Soil, Climate, and Agricultural Productions.—As Peru comprehends the whole of the mountain-masses of the Andes which lie between 15° and 5° S. lat., together with the countries on both declivities of the chain, it is naturally divided into three different regions. The country between the chain and the Pacific is called *Los Valles*, and that included between the higher ranges of the Andes, *Montaña*. The region on the eastern declivity of the Andes and the plains contiguous to it are not designated by a peculiar denomination; they may be conveniently called the *Eastern Region*.

I. The country between the steep ascent of the Andes and the Pacific varies in width from 15 to 50 miles, and may be considered as the western base of the mountains. It has a great elevation above the level of the sea, where it lies contiguous to the range, on an average between 8000 and 10,000 feet, and from this elevation it slopes towards the sea with a very irregular surface. Where it approaches the shores it is still in many parts from 1500 to 2000 feet above the sea-level, but in other places it is less than 500 feet. This irregularly inclined plain is furrowed by a number of depressions running from the Andes to the sea with a rapid slope. As the adjacent high lands frequently rise 1000 feet above them, these depressions are appropriately called *Los Valles*, or the Vales. They are traversed by rivers, many of which are dry during nine months in the year, and only a few preserve a running stream all the year round. As it never rains in the lower portion of this region, vegetation and agriculture do not extend beyond the reach of irrigation. The narrow strips along the rivers are cultivated in proportion to the supply of water. Though the upper course of the rivers is extremely rapid, few of them enter the sea, but are either lost in shallow lagoons or filter through the sand which is invariably found near their mouth. The uplands which separate the valleys from one another are covered with a fine loose sand, through which in many parts the rocks protrude, either in the form of isolated mountains, or more frequently in ridges several miles long. These uplands are complete deserts; neither beasts, birds, nor reptiles are ever seen on them, and they do not produce a single blade of vegetation. No stranger can travel from one vale to another without a guide, the sand being so loose that it is raised into clouds by the wind, and thus all traces of a path are obliterated. On account of the great heat which is experienced in these uplands in the day-time, and the clouds of sand which the wind then raises, they are usually traversed by night, and the guides regulate their course by the stars, or the light breeze which always blows from the south. The vales are most numerous in that part where the coast runs from south-south-east to north-north-west, between Lambayeque on the north and Cape Carreta on the south. In this part they are on an average 10 or 12 miles distant from one another, and have a better supply of water than in the other parts of Peru. Where the coast runs from north-west to south-east, between Cape Carreta and Arica, they are less extensive, and from 15 to 20 miles distant from each other. Farther south they are very narrow, and occur at greater intervals. In the most northern district the vales are more extensive, and contain considerable portions of cultivated ground, but they are at great distances from one another. Between Lambayeque and Sechura the desert is 90 miles across.

It is well known that the vicinity of the sea very materially influences the climate of countries, but the Pacific affects the climate of this region in a very extraordinary way, of which no satisfactory explanation has been offered.

Along the whole coast of Peru, south of Cape Blanco, a shower is never experienced, a drop of rain never falls. But for nearly five months, from June to November, the sky is covered with a kind of fog, which is called the *garua*. In the morning it is so thick and close to the ground that objects at a moderate distance cannot be seen. About ten or eleven o'clock the fog rises into the atmosphere, but does not break into clouds. This fog covers the sun so effectually as to intercept the rays, and the disk is hardly visible. During this period the earth is constantly covered with dew caused by the condensation of the fog. This dew is not heavy enough to penetrate the thinnest clothing, though it changes dust into mud, and fertilises the ground. While the garua covers the lower parts of the country, and constitutes their winter, the higher declivities of the Andes enjoy fine weather and have their summer. But in the month of January the rains on the mountains commence, and they last about three months. The rains occur however earlier in the year in the northern than in the southern districts: and hence it happens that the rivers in the northern part of Peru are full at the end of January or the beginning of February, while in the southern parts this does not take place before the end of March.

The climate of Peru is not so hot as might be supposed. In summer the weather is delightfully fine, and the heat is moderated by the sea and land breezes. The sea-breeze generally commences about ten o'clock; it is then light and variable, but gradually increases till one or two o'clock in the afternoon. A steady breeze prevails until sun-set, when it begins to die away; and soon after the sun is down there is a calm. About eight or nine o'clock in the evening light winds come off the land, and continue until sun-rise, when it again becomes calm, until the sea-breeze sets in. It is also supposed that the cold current which runs along this coast from south to north, and the temperature of which is on an average 8° lower than the mean annual temperature of the adjacent coast, may contribute to moderate the summer-heat. During the winter however, that is, during the fogs, the air is raw and damp, and woollen clothing is then necessary for the preservation of health. The mean annual temperature, according to Humboldt, is 72°, the maximum 82°, and the minimum 55°. In the day-time it varies between 72° and 77°, and in the night between 60° and 63°.

The prevailing winds along the coast blow from the south, varying between south-south-east and south-west. They are seldom stronger than a fresh breeze, especially along the coast south of Cape Carreta, where calms sometimes set in and last three or four days. Farther north they are stronger and blow with greater regularity; and near Cape Blanco they sometimes blow with great force. In winter light northerly winds are occasionally experienced. At some distance from the shores the prevailing winds blow from south and south-east, and with greater strength in winter than in summer: no thunder-storms occur; lightning indeed is seen from a distance, but thunder is never heard. Earthquakes are frequent, and sometimes destroy the towns and villages.

We do not know at what elevation above the sea-level the rains begin on the western declivity of the Peruvian Andes, but as travellers observe that cultivation and vegetation begin to increase at the height of from 8000 to 9000 feet, it is evident that such tracts must have the advantage of annual rains.

As the mean annual temperature of Peru does not much exceed that of the countries along the southern coast of the Mediterranean, all the grains and fruits of Spain succeed, and many of the intertropical products do not, which however seems attributable rather to the want of a sufficient quantity of moisture than of heat. Indian corn is generally cultivated, and constitutes the principal food of the Indians and lower classes. Rice is extensively grown in some of the wider northern vales, and is exported. Wheat succeeds only in the more elevated part of the valleys, where barley also is grown. Potatoes and sweet potatoes are generally cultivated, also mandioc, yams, and bananas to a smaller extent. The sugar-cane plantations are numerous and extensive, and sugar is exported to all the American countries bordering on the Pacific. Most of the fruit-trees peculiar to the southern countries of Europe succeed well, but those of England are not common; and walnuts, pears, apples, filberts, and almonds are imported from Chile. Vines grow in every valley, and good wine is made in several places, as at Pisco, Nasca, and Ica. There are olive-trees, but they do not supply an article of exportation, the consumption of olives in the country being considerable. There are few natural meadows; the want of them is supplied by the cultivation of lucern, which has spread over all the valleys.

The soil of the vales consists of sand mixed with vegetable mould, and does not possess a great degree of fertility. As it is cultivated every year, it requires a great deal of manure. This manure is obtained from the small rocky islands, and also from the rocky cliffs along the coast, which are covered with a layer of the excrements of sea-fowls, several feet thick, which appear at a distance as white as snow. A great number of small coasters are continually employed in conveying this manure, which is called *guano*, to the neighbouring anchorages, where it is bought by the cultivators of the soil.

II. The *Mountain Region*, or *Montaña*, runs parallel to the Pacific, and from 20 to 50 miles from the shores. It comprehends the central portion of the Andes, namely, the northern part of the Bolivian Andes and the whole of the Peruvian Andes. The Bolivian Andes consist of two elevated ranges running nearly parallel to one another from south-south-east to north-north-west, between 20° and 15° S. lat. The eastern chain contains the highest summits of the Andes, the Nevados of Illimani and Sorata, and though the western does not attain an equal elevation, it contains several summits which rise above the snow-line. The valley enclosed between the two ranges, called the Valley of the Desaguadero, is about 13,000 feet above the sea-level. The greatest part of it belongs to Bolivia; only about one fourth of it is within the territories of Peru. This valley is about 60 miles wide where it belongs to Peru; the climate and productions are noticed under BOLIVIA, vol. v., p. 86.

Between 14° and 15° S. lat., the two chains of the Bolivian Andes are connected by a transverse ridge, the mountains of Vilcanota, which do not attain the elevation of the eastern Bolivian Andes, but appear not to be inferior in height to the western chain, as several of their summits are always covered with snow. The limit of perpetual congelation on this chain, according to Pentland, occurs at 15,800 feet above the sea-level. The mountains of Vilcanota may be considered as forming the boundary-line between the Bolivian and Peruvian Andes.

The Peruvian Andes consist of two chains, which run in the same direction as the Bolivian Andes, from south-south-east to north-north-west, and may be considered as their continuation. The western range runs parallel to the Pacific, nearly north-west between 15° and 13° S. lat., and north-north-west between 13° and 5° S. lat. It is a continuous chain, without any break, and generally rises to 14,000 or 15,000 feet above the sea-level; only a few of its summits rise above the snow-line, and these elevated points are most numerous at the southern extremity, where the chain is connected with the mountains of Vilcanota. The Nevado de Chuquibamba attains nearly 22,000 feet of elevation, and exceeds in height the famous Chimborazo. South of it, and completely isolated, is the volcano of Arequipa, the summit of which is 17,200 feet above the sea, but it is not always covered with snow. Farther north-east are the elevated summits called Cerro de Huando and Cerro de Parinacocha. South-east of Lima is the Toldo de Nieve; between 11° and 11° 30′ S. lat. is the elevated summit called La Viuda, which rises to 15,968 feet; and north of it occur four other snow-capped summits, the Altun Chagua, which rises several thousand feet above the snow-line, and the Nevados of Pelagotas, of Moyapota, and of Huaylillas. The last-mentioned summit is situated in 7° 50′ S. lat., and north of it there are no snow-capped mountains until we come to Chimborazo (2° S. lat.). The mountain-mass north of the Nevado of Huaylillas seems to descend to an average height of 9000 or 10,000 feet.

The eastern chain of the Peruvian Andes, which is the continuation of the eastern Bolivian Andes, runs in its southern part, and as far north as 12° 30′ S. lat., parallel to the western Andes, at the distance of about 100 miles. It is composed of an almost uninterrupted series of snowy peaks, which terminate with the Nevado of Salcantahi (13° 10′ S. lat.). Farther north it sinks much lower, and north of 12° 30′ S. lat. the chain is interrupted by two large rivers, the Rio Yucay and the Rio Apurimac. On the northern banks of the Rio Apurimac the Andes again rise to a great elevation, though, so far as is known, in no place do they ascend above the snow-line. They gradually approach near the western Andes, and may be considered as united to them by the elevated table-land of Pasco, which is situated between 11° 10′ and 10° 30′ S. lat. At the northern side of this table-land both chains again divide, and run parallel to each other to 7° S. lat., where the eastern chain inclines to the east of north, and continues in that direction to the banks of the Amazonas, at the famous Pongo de Manseriche. Where both ranges run parallel, they are hardly more than 50 miles distant from each other, but near 5° S. lat. they are 120 miles apart. In the northern portion of the eastern chain there are a few snowy peaks, as the Paramo de Caracalla (near 7° S. lat.) and the Paramo de Piscoyana (south of 5° S. lat.).

The country included by these two ranges contains four regions, which differ materially in climate and productions. They may be called the table-land of Cuzco, the valley of the Rio Jauja, the table-land of Pasco, and the valley of the Marañon.

The *table-land of Cuzco* extends from the mountains of Vilcanota, its southern boundary, to about 12° 30′ S. lat., or more than 150 miles from south to north, and about 100 miles from east to west. Its surface is very uneven, being traversed by several ridges of broad-backed hills rising with a tolerably steep ascent, and running from the south, where they are connected with the mountains of Vilcanota, towards the north-north-west, parallel to the great chains of the Andes, which enclose this region. The valleys between these ridges are usually several miles wide, but their surface is diversified by low eminences. The whole region declines towards the north. The town of Cuzco (13° 31′ S. lat.) is 11,380 feet above the sea-level. We may reasonably infer that the districts south and west of that place are more elevated. But the rapid course of the numerous rivers which descend northward, shows that this plain lowers rapidly towards the north; and on the banks of the Rio Mantaro it probably does not exceed 8000 feet above the sea. This is also confirmed by the agricultural products. In the most elevated districts south and west of Cuzco the only cultivated grain is the quinoa (chenopodium quinoa), which is also the case in the valley of the Desaguadero. [Bolivia, vol. v., p. 87.] In the parallel of Cuzco the climate is favourable to the growth of wheat, Indian corn, and the fruits of Europe, but the last require a good deal of care, and the fruits usually met with between the tropics do not succeed. In the lower parts of the valleys north of 13° S. lat. the agricultural products consist of Indian corn, sweet potatoes, yucas, and plantains. The sugar-cane succeeds very well, and is cultivated in some parts, but not extensively. The mountains which enclose these valleys are covered with thick forests, but trees are scarce in the more elevated districts, and in some of them are entirely wanting. We are not acquainted with the climate of this region, except that there is a good deal of rain all the year round. In the valley of Paucartambo rain falls 300 days in the year.

The Vale of the Rio Jauja extends from the table-land of Pasco on the north, about 100 miles southwards, between both ranges of the Andes, and in the widest part may be about thirty miles across. Its descent from the table-land is very rapid. At its southern extremity, near 12° 30′, it is probably less than 8000 feet above the sea-level. Though this valley is the most populous district of Peru, and contains several comparatively large towns, our information respecting its climate and productions is very scanty, none of the modern travellers who have visited Peru having directed their steps to this region. We only know that the northern districts produce abundance of wheat, Indian corn, and the fruits of Europe, and that in the southern, yucas, plantains, and mandiocca are cultivated, and that the sugar-cane and tobacco are grown to a considerable extent.

The table-land of Pasco has lately been more visited by travellers than any other part of the interior of Peru, the Andes here being crossed by one ascent and one descent. The ascent from the Pacific is near the high summit called La Viuda, about 11° 10′ S. lat. and 76° 30′ W. long., and the descent is north of the Cerro Pasco, near 10° 30′ S. lat. and 75° 40′ W. long. The width of the table-land from south-west to north-east is about 60 miles, and in these parts it is enclosed by ranges which rise from 500 to 1000 feet above it. Its length cannot be determined, as the mountain-masses are broken, towards the north-west and south-east, by numerous river-courses, and do not constitute a determinate boundary, but sink imperceptibly lower. It is the highest of the table-lands enclosed within the Andes, the level parts being 14,000 feet above the sea-level. As the snow-line in this part of the Andes seems to occur about 15,500 feet above the sea, the surface of the table-land is only 1500 feet below it, which renders the climate so cold that it would have remained uninhabited but for the rich mines of Pasco, which have attracted a numerous population. The mean annual temperature probably does not exceed 40°, which is equal to that of Trondhiem in Norway, but the climate is much more disagreeable, as nearly all the year round it resembles that of the month of April at Trondhiem. Even in the midst of summer, from May to November, the nights are cold, and at sun-rise all the country is covered with hoar-frost, at which time the thermometer indicates 32°. At nine o'clock it rises 4° or 5°, and in a short time a considerable degree of heat is experienced. But the sky, which is serene in the night-time, is soon covered with fogs accompanied with a strong wind. This is followed by a fall of snow mixed with hail. This state of the weather sometimes continues for several hours; but at other times some fine intervals occur. In the afternoon, storms are frequently experienced, accompanied by frightful thunder and hail, which sometimes cause great loss of property and life. In April, two or three weeks generally pass without storms and night-frosts. In the winter, from November to March, the weather is much worse, as the snow-storms then last for weeks together. Even when the sky is serene and of a dark-blue colour, the sun looks as if it were eclipsed. The table-land is a plain divided into a considerable number of smaller plains by ridges of low hills rising a few hundred feet above their base. The surface of the level parts consists partly of bare rocks or sand. The sand is partly covered with peat, or by swamps, intersected with grassy tracts, which serve as pasture-ground for the llamas, which are kept in considerable numbers for the purpose of carrying the ore from the mines to the smelting-places. A great number of lakes are dispersed over the plain. They are very deep, and are the sources of some of the largest tributaries of the Amazonas. In the northern part of the plain is the lake of Llauricocha, the source of the Marañon, which is considered as the principal branch of the Amazonas. In the southern district is the lake of Chinchaycocha, of large dimensions, from which a river issues which is the principal branch of the Jauja, and consequently one of the greatest affluents of the Rio Ucayale. Near the eastern edge of the table-land is the lake of Quiluacocha, whence the Rio Huallaga, an affluent of the Amazonas, issues. Nothing is cultivated on this table-land, not even the quinoa.

The Vale of the Rio Marañon extends from 10° to 5° S. lat. The southern part is very narrow, the river running in a valley so contracted, that it is merely a wide ravine. This ravine continues to about 8° S. lat., where it gradually enlarges to a valley several miles wide, and more than 200 miles long. The southern part of this valley is probably not much more than 3000 feet above the sea-level, and it lowers very gradually; at its northern extremity, at the Ponga of Rentema, it is only 1250 feet above the sea. The lower part of the valley, north of 7° S. lat., is many miles wide, but not a level, as several offsets from both chains of the Andes advance some miles into it, and in several places within a short distance of the river. This valley is by far the hottest portion of the mountain region, and the vegetation in the lower parts does not differ from that of other tropical countries. Wheat is only grown on the declivities of some adjacent mountains. Indian corn, mandioca, plantains, and yucas are most extensively grown for the consumption of the inhabitants, and the sugar-cane and tobacco for exportation. We know nothing of the climate of this valley except that the heat is very great and that it has the advantage of rains. Though hardly less populous than the vale of the Jauja, it has been little visited by modern travellers.

On the west side of the Peruvian Andes, the region of the tropical productions does not ascend more than 2000 feet above the sea, but in the valleys of the mountain region it rises to between 4000 and 5000 feet, probably owing to the abundant rains which fall on the latter. The cultivated grains of this region are rice and Indian corn, and the other products are plantains, bananas, mandioca, yams, camotes, and the sugar-cane. The principal fruits are grapes, anonas, pine-apples, papaws (carica), and cherimoyers. Above this region is that of the European cerealia, which towards the Pacific reaches to 10,000 feet, and in the valleys to 12,000 feet and upwards. The grains cultivated in this region are wheat, barley, and Indian corn; potatoes and different kinds of pulse are also cultivated. The fruit-trees are those of Europe, among which the peach succeeds best. Above this region only quinoa and barley are cultivated; the latter for fodder. Potatoes succeed at a height exceeding 13,000 feet. There are no forest-trees on the western declivity of the Andes below 8000 or 9000 feet, but in the interior of the mountain region they increase in size and number in proportion as the country declines in height, and the lowest districts are covered with nearly impenetrable forests of lofty trees.

Several roads lead from the coast of the Pacific to the interior of the mountain region. Six of these roads occur south of 15° 20′ S. lat. These roads lead from Arica, Arequipa, &c., to the valley of the Desaguadero, and are named from the mountain-passes through which they lead. The most southern is the Pass of Las Gualillas (17° 50′ S. lat.), which is 14,830 feet high, and a little farther north (17° 43′) is another pass of the same name, the highest part of which is 14,200 feet. The Pass of Chullunquani (17° 18′ S. lat.) is 15,600 feet high. The lowest and most frequented pass in these parts is that of the Altos de los Huessos; it runs at the foot of the volcano of Arequipa, and where it passes the Andes (16° 21′ S. lat.) it is only 13,573 feet high. The Pass of the Altos de Toledo (16° 2′) rises to 15,528 feet, and the Pass of Lagunillas (15° 22′ S. lat.) to 15,613 feet. The last-mentioned pass, which is the most elevated, is situated where the mountains of Vilcanota join the Western Andes. A mountain-pass leads over the mountains of Vilcanota from Santa Rosa, in the valley of the Desaguadero, to Cuzco. We are imperfectly acquainted with the roads which traverse the Andes north of 15° 30′. A pass leads from Lima to the town of Huancabelica, the highest point of which is 15,080 feet above the sea-level. Farther north is the pass called Portachuela de Tacto, through which the road from Lima to Tarma passes; it is 15,760 feet high. The road which leads from the coast to the table-land of Pasco traverses the Pass of the Alto de Jacaibamba, which is 15,135 feet high, and also that of the Alto de Lachagual, which rises to 15,480 feet. The pass by which travellers descend from the table-land of Pasco to the valley of the Rio Huallaga does not exceed 14,000 feet, and runs in a ravine of the table-land. A road leads from the town of Truxillo to Caxamarca, in the vale of the Marañon, which in the Pass of Micuipampa is 11,604 feet above the sea-level. From Caxamarca a road leads northward to Chachapoyas, and from the last-mentioned place, over the Eastern Andes, to Moyabamba and Tarapoto. The most northern mountain-pass in Peru occurs near 5° S. lat., and leads over the Paramo of Guamani, where it attains the elevation of 10,950 feet above the sea-level.

III. The *Eastern Region* comprehends the eastern declivity of the Andes and the adjacent plains, as far as they belong to Peru. It is the least known portion of that country, and our information about it is extremely scanty, except as to the vale of the Rio Huallaga. This extensive valley lies east of the vale of the Marañon, being separated from it by the Eastern Andes. It extends from 10° 30′ to 7° 30′ S. lat., about 350 miles in length. The most southern part, as far north as 9° 30′ S. lat., is narrow. In this part the descent is rapid. Huanuco is about 9000 feet above the sea-level, but at 9° 30′ S. lat. the valley is probably not more than 4000 feet high. At this place it begins to widen, the Eastern Andes receding to the distance of 15 or 20 miles from the river. This may be the width of the valley to 7° S. lat., where a branch of the mountains comes close up to the river, and as high hills approach also on the east close to its banks, they form, near 6° 30′, the Pongo of Huallaga, at which the valley terminates on the north. The country north of the Pongo is quite level, and belongs to the alluvial plain of the Amazonas. The eastern boundary of the vale is formed by a range of hills, which south of 9° 30′ S. lat. probably do not fall short of 10,000 feet above the sea-level, and between 7° and 6° 30′ S. lat. rise to a considerable elevation, but between these two points they are of moderate height. The soil of the wider portion of the vale is chiefly alluvial, and as it combines great fertility with abundance of moisture and a great degree of heat, it is capable of maintaining a numerous population. At present however it is thinly inhabited, though the population of late is said to have increased considerably. There are at least one hundred very rainy days in the year, and these occur particularly in October and November. It does not appear that the dry and rainy seasons are distinguished as in other countries, showers being frequent all the year round. The heat is great, and during the rain it is frequently oppressive. The declivities of the mountains which enclose the vale are covered with thick forests of tall trees, which is also the case with the greatest part of the vale itself. Wheat and barley are grown in the southern and more elevated districts, whence they are sent to the table-land of Pasco. In the lower part, Indian corn, two sorts of plantains, and three sorts of bananas are cultivated. There are also plantations of sugar-cane, coffee, cacao, and coca. The coca is an herb much used by the Indian population, who chew it with a small quantity of lime. Fruit is here produced in greater perfection than in any other part of Peru. There are thirty-two kinds of fruit-trees. Many of these trees hardly require any care at all. There are eighteen different sorts of vegetables.

The country to the east of the range of hills which form the eastern boundary of the vale of the Huallaga, and extending from their base to the banks of the Rio Ucayali, is known under the name of *Pampa del Sacramento*. The term 'pampa' is applied in South America to level plains destitute of trees, and hence it was supposed that this part of Peru was of this description. But according to the latest information, this country is covered with woods, though they are not so dense as the forests in the vale of the Rio Huallaga. The surface also is not a level, except along the banks of the Rio Ucayali. At some distance from this river the country is diversified by numerous eminences. This country extends from the banks of the Amazonas to the Rio Pachitea, more than 300 miles from north to south, with a breadth varying between 40 and 100 miles. North of 7° S. lat. it is a dead level, and forms part of the alluvial plain of the Amazonas. As no European settlements have been established in this part of Peru, we are very imperfectly acquainted with its climate and productions. It does not suffer from oppressive heat, as the thermometer ranges only between 75° and 85° when the sun passes over the zenith In fertility and products it does not seem to be inferior to the vale of Huallaga. It is still in possession of the native tribes, of which a small number have embraced Christianity.

The country extending from the eastern banks of the Rio Ucayali to the river Yavari, which separates Peru from Brazil, is entirely unknown, except so far as it has been seen by travellers who have sailed on the Ucayali and Amazonas, where it appears to be flat and covered with woods, exactly resembling the Pampa del Sacramento in its principal features. Some hills of considerable elevation rise on the plain between 74° and 75° W. long.; and north of 7° S. lat. they are called the Sencis Hills. It is not known whether these hills extend in an uninterrupted chain south-east and then southward, until they join the eastern chain of the Andes, near 12° S. lat.; but this is the direction given to them in our maps.

The Pampa del Sacramento extends southward to the banks of the river Pachitea. The country which extends south of the last-mentioned river, from the eastern chain of the Andes to the Rio Ucayali, is likewise entirely unknown. According to information collected from the native tribes that live in this part, it is chiefly covered with mountains, which attain a great elevation near the Andes, but towards the Ucayali sink into hills. The country along its banks seems to be rather flat; it is also said to be entirely covered with forests, except in the highest summits of the mountains.

Rivers.—The rivers which descend from the western declivity of the Western Andes and fall into the Pacific have a short course, and flow with great rapidity. They are also shallow, and have very little water during the greater part of the year; many of them are quite dry for several months. Accordingly they cannot be navigated even by the smallest canoes, but the water is used to irrigate the adjacent flat tracts.

All the large rivers of Peru originate within the mountain-region, and all the waters which collect in it are united in three large rivers, the Marañon, the Huallaga, and the Ucayali. These three rivers may be considered as the principal branches of the Rio Amazonas. The Marañon, which is commonly considered as the principal branch of the Amazonas, issues from the lake of Llauricocha on the table-land of Pasco, and runs north-north-west about 150 miles in a narrow valley, and with great rapidity. In this distance it descends not less than 10,000 feet. It then flows in a wide valley for more than 250 miles to the Pongo of Rentema, and in this valley its course is rather gentle, as it descends only from about 3000 to 1232 feet. It is navigated by balsas and canoes. Near Tomependa is the Pongo of Rentema, a rapid. From this place the river turns to the north-east, and after flowing about 70 miles in that direction, it turns to the east; after a course of 70 miles more it descends into the plains by the Pongo de Manseriche, a rapid about seven miles in length. Between the Pongos of Rentema and Manseriche the river runs between lofty rocks, which sometimes rise to the height of 1000 feet, and never sink below 40 feet. It is full of eddies and rapids, and can only be navigated by balsas. At the foot of the Pongo de Manseriche is the town of Borja (in Ecuador), from which place the river is navigable for vessels drawing not more than seven feet. After its union with the Huallaga and Ucayali its depth is so much increased that it is navigable for the largest vessels.

The Huallaga, which joins the Marañon near 5° S. lat. and 76° W. long., rises in the lake of Quiluacocha, which is also on the table-land of Pasco, south-east of the lake of Llauricocha. It runs more than 500 miles. The southern half of its course is north-north-west, and the northern half north-north-east. The upper part of its course is full of rapids, which however may be descended, though not ascended. These rapids cease at Juan del Rio, south of 9° S. lat.; and the river, though rapid, affords an easy navigation as far north as 8° S. lat., where several rapids again occur. There are no rapids between 7° 30′ and 6° 40′ S. lat. Farther north occur the last rapids, which render the river nearly unnavigable for about 30 miles. North of 6° 20′ S. lat. the Huallaga flows through a level marshy plain to its junction with the Marañon, and is navigable for vessels of considerable size.

The Ucayali brings to the Amazonas the drainage of the mountain-region situated between 11° and 15° S. lat. This large river is formed by the junction of the rivers Urubamba and Tambo, which takes place near 9° S. lat. The Urubamba is formed by the union of the rivers Paucartamba and Quilabamba, which drain the eastern portion of the table-land of Cuzco, and running north, meet near 11° 30′ S. lat. These rivers are too rapid to be navigable, but the Urubamba is stated to be navigated by the natives. The Rio Tambo is formed by the confluence of the rivers Apurimac and Mantaro. The Apurimac, which drains the western portion of the table-land of Cuzco, unites with the Mantaro, which drains the valley of the Jauja, and in its upper part is called Rio Jauja. [APURIMAC.] These rivers do not appear to be navigable. The Tambo, which is formed by their union, is probably navigable, but it flows through a country in which no European settlements have been formed. Not far below the place where the Urubamba and Tambo by their union have formed the Ucayali, is a great rapid or cataract called Vuelta del Diablo. From this place downward the river runs above 500 miles, first north-north-west, and afterwards north-north-east, and no impediment to navigation occurs in this part of its course. It is navigable for large vessels. Among its chief tributaries is the Rio Pachitea. This river originates on the eastern declivity of the mountains which enclose the upper vale of the Huallaga on the east near 10° S. lat., and runs first east and then north, falling into the Ucayali near 8° 30′. As nearly the whole course is free from impediments to navigation, it has been supposed that it might be used as a channel for the exportation of the produce of the eastern districts of Peru, in preference to the Huallaga, the course of which is interrupted by many rapids and cataracts; but as the banks of the Pachitea are inhabited by native tribes who are in a state of continual enmity with the whites, it has been found impossible to establish a regular navigation on it.

Productions.—The trees and plants which are objects of cultivation have been already enumerated. The forests, with which the mountain-region and the eastern country are covered, supply several articles for commerce and for domestic use, such as vanilla, sarsaparilla, copaiva, caoutchouc, and several kinds of resins and gum; also various barks and woods, used as dyes, such as Brazil-wood, logwood, mahogany-bark, and annotto. The indigo-plant grows spontaneously. Jesuits'-bark is met with in several places on the Eastern Andes. There are various kinds of lofty trees, useful as timber or for cabinet-work, as mahogany and cedar.

Domestic animals are far from being abundant in Los Valles, on account of the want of pasture. There is a good supply of horses, and still better of mules, which are used for the transport of merchandise. On the elevated table-land of Pasco, and in other mining districts, llamas are kept for that purpose. A llama carries about 130 pounds, or half the load of a mule. Cattle are abundant in the mountain-region, where the declivities supply extensive pasture-grounds; and in some places sheep abound, especially where the situation is too cold for cattle.

Nearly all the wild animals peculiar to South America are found in Peru, as the jaguar, the puma, the spectacled bear, sloths, armadillos, ant-eaters, guanacoes, and vicuñas. Several species of monkeys occur in the eastern region, where they are used for food and dried for preservation. The condor inhabits the most elevated parts of the Andes. Parrots, parroquets, and macaws are numerous in the woods on the mountains. Whales and seals abound along the coast, and this branch of fishery is chiefly carried on by vessels from the United States of North America. Fish are plentiful in the large rivers of the eastern region, where they constitute the principal food of the inhabitants, together with the manatee and turtles. The manatee occurs only in the Ucayali and the lower part of the Huallaga. The oil extracted from the eggs of the turtle is an article of export under the name of manteca. Alligators are numerous in these rivers, and they are often thirty feet long.

Peru is noted for its wealth in silver and gold. The number of mines which have been worked is above a thousand; but most of them are exhausted, or at least abandoned. Among those which are still worked, the mines of Pasco are the richest. Formerly the annual produce of these mines amounted to eight millions of dollars, or 1,800,000*l.*; but at present it probably falls short of half that sum. There are quicksilver-mines near Huancabelica, which were formerly very rich: we do not know in what state they are now. Copper, iron, lead, and brimstone are found in several places. Saltpetre is found in the country adjacent to the Pacific, south of Arequipa, and great quantities of it are exported by English vessels. It is not a nitrate of potash, but of soda. Salt is collected on the coast north of Callao, at Point Salinas, and in Sechura Bay, where there are salinas, or salt-ponds. Nearly all the mines of the precious metals are on the most elevated parts of the Andes above the line to which cultivation extends, a circumstance which renders the working of these mines very difficult and expensive.

Inhabitants.—No census having been taken, the population is vaguely estimated at 1,800,000, composed of creoles, or descendants of Europeans, Peruvian Indians, and a mixed race. The greater part of the eastern region is in possession of independent tribes, and only those natives who inhabit the vale of the Huallaga have been converted and subjected to the government of the whites. The number of creoles is stated to amount to about 250,000, and that of the Peruvian Indians to near 1,000,000; the remainder are a mixed race, the offspring of Europeans and Indian women.

The Peruvian Indians inhabit the Valles and the Montaña, to the exclusion of all other native tribes. They speak the Quichua language, which is generally called the language of the Incas, and which is used by all the natives of South America, from Quito near the equator, to Tucuman in La Plata, 27° S. lat. The Peruvian Indians had attained a considerable degree of civilization at the time of the arrival of the Spaniards, a fact which is proved by the numerous ruins of extensive buildings, the remains of the great artificial road which leads through the Montaña from Quito to Cuzco, and thence southward over the valley of the Desaguadero; and more particularly by the fact that they irrigated the low tracts in the vales by making cuts to convey the water from the small rivers over the fields, and by the judicious manner in which the water was distributed. It may be said that their condition has been improved by the conquest, inasmuch as they acquired iron implements and domestic animals to assist them in their agricultural labour; but they have not been benefited in any other respect. These Indians apply themselves particularly to agriculture, and there are numerous villages, and even small towns, the whole population of which now consists of Peruvians. They also work in the mines, and manufacture different kinds of woollen and cotton cloth. These kinds of manufactures existed before the arrival of the Spaniards, and must have existed in a country where the climate obliges the people to put on warm clothing for several months in the year. They are also fishermen, and sail with their balsas along the coast from one small port to another to exchange their different productions.

The native tribes which inhabit the vale of the Huallaga river have been converted, and are nearly equal in civilization to the Peruvians. The Shanamachos live on the eastern banks of the Huallaga, and on the western are the Cholones, Sharras, and Ibitas. They all seem to belong to one nation, as they speak one language, called the Ibita, though most of them understand the Quichua. They cultivate the grains and roots which have been mentioned as the principal productions of this valley. Their dwellings are much inferior to those of the Peruvians, which however may be attributed to the circumstance of their country not being exposed to cold weather. They have adopted a decent dress, except that they wear no covering for the head or feet, which they stain blue.

The independent native tribes inhabit the low and level country east of the mountain region. It is more than probable that all these tribes are not known, even by name. South of 12° S. lat., on the east of the Andes, are the Chunchos and Tuyoneris. The Antes inhabit the country where the Paucartamba and Quilabamba unite, between 12° and 11° S. lat. North of 11°, and as far north as 9° S. lat., are four tribes, the Tampas, Palutuniques, Chuntaguirus, and Piros. The country on both sides of the Pachitea river is in possession of the numerous and warlike tribe of the Cashibos, who are said to be cannibals, and do not permit strangers to enter their country. They have advanced as far north as 8° S. lat. North of them, between the Huallaga and Ucayali, are the Conibos, Setebos, and Shipebos; and still farther north two small tribes, the Maparis and Puinaus. Between the Ucayali and Yavari are the Amajuacas (between 9° and 8°), the Remos (between 8° and 7°), the Sencis and Capanaguas (7° and 6°), and the numerous tribe of the Mayorunas, who occupy the country to the very banks of the Amazonas. The tribes inhabiting both banks of the Ucayali speak one language, or dialects which differ very little from one another. This language is called Pano. Some of these tribes have been partially converted to Christianity, as the Conibos, Setebos, and Shipebos, but the missionaries have made no impression on the other tribes, and no attempt at conversion has been made among some of them. Since Peru has obtained its independence, the missions have been much neglected, and many of the converted Indians have returned to the woods, and are again lost to civilization. The converted tribes are agriculturists, which is also the case with several of the unconverted tribes, as the Chunchos, Antes, Remos, and Sencis; but they cultivate only small patches of ground, and prefer wandering about in the forests in pursuit of game. The converted tribes wear clothing, but the others go quite naked. None of these tribes have any chief, but they all live in a state of perfect equality. Even in their excursions against their enemies they have no leader, but each warrior acts individually, and appropriates to his own use all the plunder or prisoners that he takes. They use a few articles of European manufacture, as hatchets, knives, scissors, needles, buttons, and some glittering baubles. They procure these articles either at Nauta on the Amazonas or at Sarayacu on the Ucayali. The Chuntaguirus, who are the most remote from all the settlements of the whites, ascend the Ucayali and Urubamba to the confluence of the Paucartamba and Quilabamba, where they procure by barter such articles as they want, giving in exchange parrots and other birds, monkeys, cotton robes white and painted, wax, balsams, the feet of the tapir, feather ornaments for the head, and jaguar and other skins.

Political Divisions and Towns.—Peru is divided into eight departments, Truxillo, Junin, Lima, Huancabelica, Ayacucho, Cuzco, Arequipa, and Puno. The countries inhabited by the independent tribes are not comprised in these departments.

1. The department of *Truxillo* extends over the northern districts of the republic, from the shores of the Pacific to the basin of the Rio Huallaga, and comprehends the Valles north of Santa (near 9° S. lat.), the lower and wider portion of the vale of the Marañon, and likewise the greater part of that of the Rio Huallaga. The mountains contain many mines, several of which are still profitably worked. It also produces great quantities of sugar, which is exported. On the eastern chain of the Andes, in a district called Huamalies, a great quantity of Jesuits'-bark is collected. The number of creoles is comparatively small, and that of the Indians very great. There are numerous ruins of antient buildings in the Valles and vale of the river Marañon. Payta is a commercial town with an excellent harbour, which in 1835 was visited by upwards of 4000 tons of shipping. The town, which is built on the slope and at the foot of a hill, contains 5000 inhabitants. It is the port of the fine vale of the Rio Piura, which contains 75,000 inhabitants, and is a place of much business, as communication with Europe by the way of Panamà is more expeditious than at any other port of Peru. The town of S. Miguel de Piura, built on the banks of the river, about 20 miles from Payta, contains a population of from 8000 to 9000, and some manufactures of soap and leather. Lambayeque is situated in a district which produces abundance of rice and has a considerable commerce, though the roadstead is bad. It contains about 4000 inhabitants, and exports bullion and rice. Truxillo, founded by Francisco Pizarro and named after his birthplace, is situated in the middle of the extensive valley of Chimu, about two miles from the sea. The harbour Huanacho is an open roadstead. The streets of Truxillo are wide and regular, and it has a fine cathedral and a handsome townhall. The principal articles of export are bullion, sugar, and rice. Population 9000. The valley of Chimu contains the ruins of a large Indian town. In the vale of the Marañon are the towns of Caxamarca and Chachapoyas. Caxamarca stands on the eastern declivity of the Western Andes, in a rich mining district: it is nearly 9000 feet above the sea-level, and contains 7000 inhabitants and the ruins of a palace of the Incas. Cotton and woollen cloth are manufactured to a considerable extent, and also many utensils of iron. In the neighbourhood there are hot springs, called the baths of the Incas. The richest mine in the vicinity is that of Qualgayac, not far from Chota. The town of Chachapoyas is near the western declivity of the Eastern Andes, on the road which leads to the vale of the Rio Huallaga, and contains 3000 inhabitants. Much tobacco is raised in the neighbourhood. In the vale of the Rio Huallaga are the towns of Moyobamba and Tarapoto. Moyobamba, near the eastern declivity of the Eastern Andes, has 5000 inhabitants, and Tarapoto, a few miles from the Huallaga river, about 4000. In both towns a coarse cotton stuff called *tucuya* is made; and cotton, gums, resin, and white wax are sent to the coast of the Pacific by the road which leads from Tarapoto to Truxillo.

2. The department of *Junin* was formerly called *Tarma*, from the principal town, but the name was changed to commemorate the battle gained by Bolivar on the plain of Junin in 1824. It occupies the valleys along the Pacific which lie between Santa and Barranca (near 11° S. lat.), and comprehends the upper vales of the rivers Marañon, Huallaga, and Jauja, and also the table-land of Pasco. Besides the produce of the rich mines, this department exports sugar, rice, and Indian corn. The greater part of the district of Huamalies, in which bark is collected, belongs to this department. The Indian population is still greater in proportion to the creoles than in Truxillo. There are several ruins of antient buildings, but they are not considerable. None of the towns situated in the Valles are important in a commercial view. The fertile valley of the Rio Nepeña contains the towns of Huambacho and Nepeña; the last-mentioned town seems to be a place of some size. They export their produce, sugar and grain, from the excellent harbour of Samanco or Huambacho. Farther south is the town of Guarmey, in a country which is covered with lofty trees, whence great quantities of fire-wood are sent to Lima. It has only from 500 to 600 inhabitants. The small towns of Barranca and Supé export their agricultural produce to Lima from the bay of Supé. In the upper vale of the Marañon is the town of Huari, with 7000 inhabitants, and Caxatambo, which has some mines in the neighbourhood. Pasco or Cerro Pasco is built on the table-land of Pasco, 14,278 feet above the sea-level. It is probably the most elevated place in America, if not in the world, which is permanently inhabited. This town, whose population fluctuates, according to the produce of the mines, between 12,000 and 16,000, is irregularly built on very uneven ground. The site on which it stands abounds in silver ore, and the mouths of the mines are frequently in the middle of the streets. Only those mines are worked which

contain rich ores. The houses are low, and some have small glazed windows; but the suburbs are merely a collection of mud cottages. As the surrounding country is destitute of trees, it is fortunate that coal abounds in the neighbourhood. In the upper vale of the Rio Huallaga, north-east of Pasco, is the town of Huanaco, with 9000 inhabitants, which owes its prosperity to the circumstance of its agricultural produce finding a ready sale at Pasco. In the neighbourhood there are ruins of considerable extent. In the vale of the Rio Jauja is the town of Tarma, with 6000 inhabitants, in which cotton and woollen stuffs are manufactured.

3. The department of *Lima* extends along the coast from Barranca (11° S. lat.) to Point Penates (15° 30′), and comprehends that part of the maritime region in which the valleys are most numerous and occur at short distances from one another. It extends inland to the lower declivity of the Western Andes. All the productions of the vales grow here, and are tolerably abundant. The population contains a greater proportion of creoles than that of the other departments. There are some extensive ruins of antient buildings and towns. North of Lima is the town of Huacho, built in an extensive and fertile valley about one mile from the port, which is small, but has good anchorage. Lima, the capital of the republic, is about 6 miles from Callao. [Lima; Callao.] South of Callao is the small town of Chorillos, built on a cliff at the foot of the Morro Solar, a remarkable cluster of hills; it is chiefly used as a bathing-place for the inhabitants of Lima. In the fertile and well-cultivated valley of Lurim, which is a few miles farther south, are the ruins of the antient city of Pachacamac. Cerro Azul, farther south, in the middle of a fertile valley, is a considerable place, and exports large quantities of rum, sugar, and chancana, a sort of treacle. Pisco, built on a plain, about a mile from the shores of the Bay of Pisco, has above 3000 inhabitants. It has a considerable commerce, and exports wine, a kind of spirit called Pisco or Italia, and sugar. South of Pisco are two small towns, Yca and Nasca, in which much wine is made, and exported to other parts of Peru; but it is inferior to that of Pisco.

4. The department of *Huancabelica* lies east of Lima, and extends over the Western Andes and the lower vale of the Jauja. The mountains contain a great number of mines, and several of them are still worked with profit. The fertile vale is well cultivated and inhabited, as it supplies the mining district with provisions. The number of creoles is considerable. The capital, Huancabelica, is built in a ravine between mountains whose summits rise to the height of 13,000 feet, and which contain several mines of gold, silver, and quicksilver; the quicksilver-mines are rich. The town has 5000 inhabitants. Nothing is cultivated in the neighbourhood. Castro Vireyna, farther south, is in the centre of another mining district. In the vale of the Rio Jauja is Jauja or Atanjauja, a town with 3000 inhabitants, and some silver-mines in the neighbourhood.

5. The department of *Ayacucho* received its name from the plains of Ayacucho, on which General Sucre, on the 9th of December, 1824, defeated Canterac, the viceroy of Peru, and put an end to the dominion of Spain in South America. It extends over a part of the Western Andes, the western lower portion of the table-land of Cuzco, and the valley of the Rio Mantaro. The principal productions are the cerealia and fruits of Europe. The population consists of Indians: whites are only found in the town. The capital is Huamango, a large place with 26,000 inhabitants, founded by Francisco Pizarro, in an elevated situation, on the declivities of some mountains of moderate elevation above their base. It contains several large private buildings of stone, covered with tiles. The suburbs, which are inhabited by Indians, are large, and the houses better than in other Indian towns. It has a fine cathedral, a university, and a seminary for clergymen. The rich creole families that live in this town have large sugar-plantations in the valley of the river Mantaro. As the town is situated on the road leading from Lima to Cuzco, it has a considerable trade. Some miles east-north-east of the town are the plains of Ayacucho. North of it is Huanta, a small town, in a district rich in agricultural produce, especially wheat and Indian corn.

6. The department of *Cuzco* extends over the whole of the southern and over the greater portion of the northern part of the table-land of Cuzco. The Peruvians are very numerous in this country, and in many places ruins of antient buildings occur. The southern districts contain extensive pasture-grounds: those situated in the middle produce wheat and the other cerealia of Europe, with Indian corn in abundance, and the southern have extensive plantations of sugar and other intertropical plants. In the southern districts are several mines, but few of them are worked. Besides the capital, Cusco, or Cuzco [Cuzco], there is no town of importance in this department. Abancay, in the narrow valley of the upper Apurimac, is a small place. The plain which lies east of the eastern Andes contains a small number of plantations near the base of the mountains; they belong to this department, and border on the country of the Chunchos Indians.

7. The department of *Arequipa* extends along the coast of the Pacific from Point Penates (15° 30′ S. lat.) to Point Sama (18° S. lat.), and inland to the declivity of the western Andes. It contains a smaller number of vales than the department of Lima, but several of them are extensive, especially that of the Rio Chila or Arequipa, in which the town of Arequipa stands. The commercial products consist chiefly of wool and cotton. There are more creoles than in any other department except Lima. Acari, not far from the boundary of the department of Lima, is built in a fertile plain several miles from the sea. It is a considerable place, but little visited by travellers. The port, called Point Lomas, has good anchorage and tolerable landing. Islay, the harbour of Arequipa, contains about 1500 inhabitants. It is built on the west side of a hill which slopes gently towards the harbour. The trade is flourishing, and it exports bark, wool, and specie. On the north-east of the capital, Arequipa [Arequipa], stands the volcano of Arequipa, 17,200 feet high. There is always snow on the north-west side of its summit. Ylo is a small place on the coast.

8. The department of *Puno* extends along the Pacific from Point Sama (18° S. lat.) to the Rio Loa, which constitutes the southern boundary of Peru. It comprehends also that part of the valley of the Desaguadero which belongs to Peru. The vales along the coast are small, and in general 20 miles from one another. The rivers which drain these valleys have in general water only during three months of the year. In the barren tracts which divide the valleys much saltpetre is collected, and in some silver and copper ore are found. The population is more scanty than in any other part of Peru, and chiefly consists of Indians. The principal town on the coast is Arica, which contains a population of about 3000 souls, who live in low houses built of sun-dried bricks. [Arica.] It is the port of Tacna, a town built in the same valley about 30 miles from it, and the depôt of European merchandise for the consumption of the department of Puno and the greater part of the republic of Bolivia. Tacna contains 7000 souls and several well-built houses. Yquique (20° 12′ S. lat.), with a bad roadstead, has only 1000 inhabitants; a considerable quantity of saltpetre is shipped here. Near the lake of Titicaca, in the valley of the Desaguadero, are the towns of Puno, the capital of the department, which has a population of 9000 inhabitants, and Chuquito, with 5000. In the vicinity of Puno are numerous silver-mines, which in 1805 yielded 96,528 marcs of silver, but since that time the produce has fallen off.

In the countries of the independent tribes there were formerly several *missiones*, or stations of missionaries, who collected a number of aborigines and tried to convert them to Christianity. Nearly all these missions have been destroyed by the political changes to which Peru has been subject during the last twenty years. Only one of them is in a flourishing state, that of Sarayacu, on the Rio Ucayali, near 7° S. lat., where about 2000 individuals of the tribes of Puinaus, Setebos, Conibos, Shipebos, and Sencis live in scattered houses, and seem to advance, though slowly, in civilization.

Manufactures.—The Peruvian Indians consume a very small quantity of European manufactured articles. Their dress is composed of cotton or woollen stuffs made at home, or in several of the small towns in the vale of the Marañon and Jauja. These home-made stuffs also serve as the dress of the mixed race. Only the creoles dress in European stuffs. There are some manufactures of cordovan leather, and some tanneries and soap-houses. The iron utensils, such as hatchets, scissors, &c., made in Caxamarca, are highly valued. In the large towns many persons are occupied with making vessels, utensils, and ornaments of gold and silver.

Commerce.—The country is too mountainous to admit the making of carriage-roads in the interior. Mules are generally used by travellers and for the transport of merchandise. In the more elevated parts of the country llamas are employed for the latter purpose. Six great roads traverse the country from west to east; the most northern runs from Truxillo to Caxamarca, Chacapoyas, Moyabamba, and Tarapoto. One road leads from Lima to Pasco, another to Tarma, and a third to Huancabelica, Hacamango, and Cuzco. A road leads from Islay to Arequipa and Puno, and another from Arica to Tacna, and thence to La Paz and Oruro in Bolivia. The goods imported from foreign countries are sent by these roads into the interior of Peru.

The foreign commerce is considerable, especially that with the other countries of America bordering on the Pacific, and also with Europe. The most important article of export is the produce of the mines, especially silver. The second in importance is sugar, which is sent to Mexico, New Granada, Ecuador, and Chile. The third article in importance is perhaps saltpetre, the quantity sent to different countries of Europe being very great. Cotton, tobacco, Indian corn, rice, salt, and spirits are minor articles. Wheat, flour, wine, and fruits are imported from Chile, with which country there is an active commerce. Manufactured goods are received from Europe and from the United States of North America, and from Canton silk goods and nankeens.

The principal harbours from which the exports are made, are Payta, Lambayeque, Callao, Pisco, Islay, Arica, and Iquique. We have no recent account of the commerce of the first four harbours, in which probably three-fourths of the exports are shipped. The three last-mentioned harbours are called puertos intermedios, and are usually visited by European vessels which sail along the coast from Valparaiso in Chile to Callao. Nothing is imported into Iquique, the most southern of these harbours, but in 1834 not less than 148,150 cwt. of saltpetre were shipped, of which more than 100,000 was on account of British merchants. The value amounted to 125,000*l.* The number of European vessels which entered the port of Arica in 1834 was 63, and their tonnage amounted to 15,094; there were 17 English vessels, of 3651 tons, 8 French vessels, of 2003 tons, and 10 vessels from the United States of North America, with 2971 tons. The other European vessels were from Antwerp, Hamburg, Cadiz, and Genoa. The vessels from Chile and other parts of Peru were 26 in number. They exported bullion and specie to the amount of 320,301 Spanish dollars, equal to 72,052*l.*; bark to the value of 175,552 dollars, or 39,504*l.*; pewter to the amount of 18,285 dollars, or 4114*l.*; and wool to the amount of 13,252 dollars, or 2982*l.*; chinchilla and vicuña skins, hides, and cotton were among the minor articles of export. In the same year 132 cwt. of copper were brought from the Bolivian part of the valley of the Desaguadero and shipped at Arica. The value of all the exports of Arica does not exceed 150,000*l.* The exports of Islay in the same year amounted to 1,135,590 dollars, equal to 255,507*l.*, viz:—

	Dollars.
Saltpetre	776,000
Silver	124,503
Bark	110,872
Vicuña wool	45,000
Sheep-wool	73,070
Copper	2,500
Rataña	3,645
	1,135,590

The exports of the puertos intermedios, shipped for Europe and the United States, amounted therefore to 530,507*l.*; and as it is assumed that only one-fourth of the commerce of Peru is concentrated in these harbours, the whole exports of the country would exceed 2,000,000*l.*, exclusive of the commerce with Mexico, Central America, and Chile. But it must be remembered that a great part of the exports of the puertos intermedios is brought from Bolivia, as the silver, bark, vicuña and sheep wool, and copper.

History.—When the Spaniards first visited Peru, they found the country under a well-regulated government, and inhabited by a nation which had made great progress in the arts of civilization. The people were decently dressed, and lodged in comfortable houses. Their fields were well cultivated, and artificial cuts had been made to conduct the water of the small rivers to a considerable distance for the purposes of irrigation. They had extensive manufactures of earthenware and woollen and cotton cloth, and also tools made of copper. Even now the elegant forms of their utensils, made out of the hardest rock without the use of iron tools, excite admiration. The extensive ruins of palaces and buildings scattered over the country, and the remains of the great road which led from Quito to Cuzco, and thence southward over the table-land of the valley of the Desaguadero, show that the nation was far advanced in civilization. This civilization appears to have grown up in the nation itself, and not to have been derived from communication with other civilised people. The navigation of the Peruvians was limited to coasting from one small harbour to another in balsas. The difference in political institutions and in the usages of society between the Peruvians and Mexicans precludes the supposition of either of these two nations having received their civilization from the other. Besides this, they were divided by savage tribes, which were sunk in the deepest barbarism. The Spaniards were surprised to find this state of things in Peru. When they had got possession of the country, they inquired into its history, and learned the following traditions:—

About three centuries before the arrival of the Spaniards, Manco Capac and Mama Ocollo appeared on the table-land of the Desaguadero. These two personages, male and female, of majestic stature, appeared clothed in garments, and declared that they were children of the sun, and sent by their parent to reclaim the human race from its misery. The savage tribes submitted to the instruction of these beings of a divine origin, who taught them the first arts of civilization, agriculture, and the manufacture of clothing. Manco Capac organised a regular government, and formed his subjects into four different ranks or classes, which had some slight resemblance to the castes of the Hindus. He also established many useful customs and laws, and founded the town of Cuzco, which soon became the capital of an extensive empire, called the empire of the Incas (or lords) of Peru. He and his successors, being considered as the offspring of the divinity, exercised absolute and uncontrolled authority: disobedience to their orders was considered a sin and violation of the commands of the Supreme Being. His successors gradually extended their authority over the whole of the mountain-region between the equator and 25° S. lat. As the aborigines who inhabit this extensive country speak one language, the Quichua, it must be supposed that they belong to one race, and thus were easily united into one nation, and peaceably submitted to one government. When the Spaniards first entered Peru, the twelfth monarch from the founder of the state, named Huayna Capac, was said to be seated on the throne. He had violated the antient usage of the Incas, which forbade a monarch to marry a woman not a descendant of Manco Capac and Mama Ocollo. His wife was a daughter of the vanquished king of Quito, and the son whom she had borne him, named Atahualpa, was appointed his successor in that kingdom. The rest of his dominions he left to Huascar, his eldest son by a princess of the Inca race. This led to a civil war between the two princes, and when the contest was at its height, a Spanish force entered the country under Francisco Pizarro in 1531.

Pizarro had sailed in 1526 from Panamà to a country lying farther south, which, according to the information collected from the natives, abounded in precious metals. He sailed along the coast as far south as Cape Parina or Cape Aguja. Landing at Tumbez in the Bay of Guayaquil, the most northern point of the present republic of Peru, he was struck with the advanced state of civilization of the inhabitants, and still more with the abundance of gold and silver vessels and utensils. From this time he resolved on the conquest of the country. In 1531 he returned with a small force which he had procured from Spain, marched along the coast, and in 1532 built the town of St. Michael de Piura, the oldest Spanish settlement in Peru. The distracted state of the country caused by the civil war enabled the Spaniards to take possession of it without a battle; and though the Peruvians afterwards tried to renew the contest, they were easily defeated and compelled to submit to a foreign yoke. In many instances during the progress of the conquest (from 1532 to 1534), Pizarro acted with cruelty and perfidy, but he undoubtedly possessed great political sagacity. All the large towns now existing in Peru were built by Pizarro, with the exception of Cuzco, which was founded by Manco Capac. Pizarro built Piura, Truxillo, Lima, Arequipa, and Huamanga.

The disorders which immediately followed the conquest nearly caused the loss of the country, a circumstance which determined the court of Spain to make Peru the chief seat of the Spanish dominions in South America. Lima was chosen for the capital, and it soon rose to such opulence that it was called the City of the Kings. The authority of Spain took deeper root in Peru than in any other of her South American colonies. In 1780 the Peruvians took up arms against the Spaniards, under Tupac Amaro, an Inca, but failing to capture the town of La Paz after a long siege, they again submitted. When all the Spanish colonies began to rise against the mother country, after the year 1810, Peru remained quiet, and though some of the neighbouring provinces had already expelled the Spanish armies, and others were attempting to do the same, the Spaniards remained in undisturbed possession of Peru until 1820, and even then the first impulse to rebellion came from without. General San Martin had collected a force in the provinces of La Plata, with which he entered Chile, and, after a successful war, expelled the Spaniards from that country. In 1820 he came with an army from Valparaiso to Peru, and as soon as he had obtained possession of Lima, the independence of Peru was proclaimed on the 28th of July, 1821, and San Martin was also proclaimed protector of Peru. The Spanish viceroy Canterac, who had remained in possession of the Montaña, gradually recovered the Valles. San Martin, who had lost his popularity, resigned his authority into the hands of the legislature on the 19th of August, 1822. On the 1st of September, Bolivar, the Columbian general, entered Lima, and continued the war with Canterac, but at first with doubtful success. In November, 1823, a constitution proposed by Bolivar was adopted, but the Congress, being unable to maintain its authority, dissolved in February, 1824, and Bolivar was made dictator. After some advantages gained by Bolivar over Canterac, the latter was entirely defeated by Sucre in December, 1824, in the plains of Ayacucho, by which battle the authority of Spain in Peru and South America was annihilated. General Rodil threw himself with 8000 men into the fortress of Callao, which he surrendered, after a siege of more than thirteen months, on the 29th of January, 1826. In February, 1825, Bolivar had resigned the dictatorship, but he had previously contrived to separate the southern provinces from the northern, and to convert the former into a new republic, which adopted the name of Bolivia. The different forms of government which had been tried within the six years following the declaration of independence, were not adapted to the state of society and the circumstances of the nation. Towards the end of 1826, the Bolivian constitution was adopted, according to which a president was to be placed at the head of the government, with the power of naming his successor, and without being subject to any responsibility for his acts. This new constitution excited great discontent, and as Bolivar was soon afterwards obliged to go to Columbia, where an insurrection had broken out and a civil war was on the point of commencing, a complete revolution took place in Peru, in January, 1827. The Bolivian constitution or government was abolished, and a new constitution framed and adopted, which may be considered as still in force. This constitution may be viewed as an attempt to unite a federal republic with a central government. The provincial governments of the departments have the power of framing laws for the provinces, but these laws do not obtain authority till they have been approved by the Congress. The provincial governments however are entitled to the uncontrolled administration of their own affairs, both civil and ecclesiastical. The national congress, or supreme legislature, consists of two bodies, a senate and a house of representatives. The president, in whose hands the executive power is placed, is chosen for four years, and he cannot be re-elected. He is assisted in the administration of the public affairs by a ministry of his choice, and by a state council, which is elected by the legislature. The judicial power is independent of the executive, and all decrees and judgments are to be made public. The highest officers of the central government in the departments are the prefects and subprefects. These persons, as well as the judges, are elected by the Congress from three candidates, who are proposed by the provincial governments. The Roman Catholic religion alone can be publicly exercised. Peru has experienced, even more than the other parts of America which once were subject to Spain, the bad effects of having adopted a constitution unsuited to the state of society. The country is almost continually distracted by parties which are struggling for power, and by civil wars and revolutions produced by these continual struggles. In 1835 four chiefs in arms were contending for supremacy. If one of them succeeded in making himself powerful, the others united against him; but no sooner were they victorious, than they were again disunited and in hostility to each other. In 1836 the four southern departments, Cuzco, Ayacucho, Puno, and Arequipa, separated from the four northern, and constituted an independent state, under the name of Estado Sud Peruano. We do not know whether the two parts of Peru have again united under one government, or continue to form two republics.

(Ulloa's *Voyage to South America*; Humboldt's *Personal Narrative*, &c.; *Memoirs of General Miller*; Meyen's *Reise um die Welt*; Poeppig's *Reise in Chile, Peru, &c.*; Smyth's and Lowe's *Narrative of a Journey from Lima to Para*; *Narrative of the Surveying Voyages of the Adventure and Beagle*; Pentland, in the *London Geographical Journal*, vols. v. and viii.; Miller, in the *London Geographical Journal*, vol. vi.)

PERUVIAN ARCHITECTURE. Remains of antient Peruvian buildings are dispersed over the western parts of South America, from the equator to 15° S. lat., especially over the Montaña. They are characterised by simplicity, symmetry, and solidity. There are no columns, pilasters, or arches, and the buildings exhibit a singular uniformity and a complete want of all exterior ornaments.

The great road of the Incas, which runs from Quito to Cuzco and the table-land of the Desaguadero, is made of enormous masses of porphyry, and it is still nearly perfect in several parts of the Montaña. Humboldt obtained an antient Peruvian cutting instrument, which had been found in a mine not far from Cuzco: the material consisted of 94 parts of copper and 6 of tin, a composition which rendered it hard enough to be used nearly like steel. With instruments made of this material the Peruvians cut the enormous masses of which their buildings are composed. Some of the buildings near Cuzco contain stones 40 feet long, 20 feet wide, and nearly 7 feet thick. These stones are fitted together with great skill, and, as it was supposed, without cement. But Humboldt discovered in some ruins a thin layer of cement, consisting of gravel and an argillaceous earth; in other edifices, he says, it is composed of bitumen.

The stones are all parallelopipedons, and worked with such exactness that it would be impossible to perceive the joinings if their exterior surface were quite level; but being a little convex, the junctures form slight depressions, which constitute the only exterior ornament of the buildings. The doors of the buildings are from 7 to 8¼ feet high. The sides of the doors are not parallel, but approach each other towards the top, a circumstance which gives to the Peruvian doorways a resemblance to those in some of the Egyptian temples. The niches, of which several occur in the inner side of the walls, have the form of the doors.

The most extensive Peruvian buildings occur in the table-land of Cuzco, which was the most antient seat of the monarchy of the Incas. There are also antient remains within the boundaries of the present republic of Ecuador. Near the ridge called Chisinche, not far from the volcano Cotopaxi, are the ruins of a large building called the Palace of the Incas. It was a square, of which each side is about 30 yards long, and it had four doors. The interior was divided into eight apartments, three of which are still in tolerable preservation. Not far from the mountain-pass of Assuay is a building called Ingappilca, or the Fortress of Cañar, consisting of a wall of very large stones, about 5 or 6 yards high; it has a regular oval form, of which the greatest axis is nearly 40 feet long. In the ruins of the town of Chulucanas, in the department of Truxillo, near the boundary-line between Peru and Ecuador, Humboldt had an opportunity of observing the construction of the private buildings of the Peruvians, and he observes that they consist of one room only, and that probably the door opened into a court-yard. (Humboldt's *Vues des Cordillères et Monuments des Peuples Indigènes, &c.*)

PERU'GIA, DELEGAZIO'NE DI, a province of the

Papal State, is bounded on the north by the central ridge of the Apennines, which separates it from the province of Pesaro e Urbino, on the west by Tuscany, on the south by the provinces of Spoleto and Viterbo, and on the east by the provinces of Macerata and Spoleto. Its length from the Apennines, which border the valley of the Tiber above Città di Castello, down to the confluence of the Paglia with the Tiber, is about 60 miles, and its breadth varies from 20 to 35 miles. The area is reckoned at about 1790 square miles. The province of Perugia is entirely in the basin of the Tiber. The lake of Perugia (Lacus Trasimenus) lies in the territory of Perugia, near the borders of Tuscany; its circumference is about 30 miles, the greatest width is about eight miles, but the depth is not more than 30 feet. It contains three small islands; two (of which one is called Isola Maggiore) are towards the north, and the third (called Polrese) towards the southern extremity. This lake is enclosed by hills on the north, east, and south, but the western coast is more open, merging into the wide plain of Cortona. This lake is fed by no permanent river, but by numerous springs which rise from the bottom of the bed; it has no natural outlet, and in seasons of rain, when numerous streams run into it from the neighbouring hills, it suddenly overflows the banks, and sometime the waters have entered the plain of Cortona, and mixing with those of the Chiana, have flowed into the Arno. In order to prevent the mischief occasioned by these floods, a tunnel or emissary has been made through a hill on the south-east bank near the parish church of San Savino, opposite the island of Polrese. The mouth of the emissary is about six feet high and five wide, and the length is 2845 feet; it is entirely cased with masonry. Seven shafts open into it from the sides of the hill at various distances along the length of the tunnel, and give access to the workmen for clearing and repairing it. The water on issuing out of the tunnel flows into a canal, sets in motion several mills, and after a course of about two miles enters the river Caïna, an affluent of the Nestore, which is an affluent of the Tiber. The mouth of the emissary is above the ordinary or summer level, and the water flows into it only in the winter or after heavy rains. (Vestrini, 'Dissertazione sull' Emissario del Lago di Perugia,' in vol. vii. of the *Memoirs of the Academia Etrusca di Cortona.*) The construction of this important work is due to Braccio da Montone, a distinguished chieftain, and lord of Perugia in the beginning of the fifteenth century. Some pretend that the emissary existed long before, and was only repaired by Braccio, but there is no evidence in support of this assertion. The emissary became encumbered in course of time, and a great flood occurring in 1602, the waters of the lake inundated the plain of Cortona, and did great mischief in other places along the banks. After this misfortune, Pope Clement VIII. ordered the emissary to be repaired. Campanus, 'De Rebus Gestis Andreæ Brachii,' 6th book, gives a pleasing description of the lake of Perugia, its wide expanse, its limpid waters, its verdant and picturesque green banks, and the towns and villages scattered along the shore. Seen from the hills of Spelonca, between Ossaia and Passignano, on the high road from Florence to Perugia, the lake has a very fine appearance. This lake is subject to sudden storms.

The site of the battle between Hannibal and the Romans has been a subject of much contention among the learned. It is generally supposed to be near Passignano on the north-east side of the lake, where the hills recede from the shore, forming a kind of valley or dale between them and the lake. The province of Perugia is chiefly hilly, being crossed by offsets from the Apennine chain, which stretch southwards in a direction parallel to the course of the Tiber. South of the town of Perugia are some extensive plains, one of which lies eastwards towards Foligno, and another on the western or right bank of the Tiber, towards Città della Pieve. The principal affluents of the Tiber in the province of Perugia are—1, the Chiascio, which rises in the central Apennine ridge, and flowing southwards receives the Topino, which comes from the valley of Foligno, after which the united stream enters the Tiber a few miles below Perugia; 2, the Nestore, which rises near Città della Pieve, flows south of the hills which border the southern bank of the lake of Perugia, receives the Caïna from the north, and after a course of about 35 miles enters the Tiber; 3, the Naja, a torrent which rises in an offset of the Apennines that separates the valley of the lower Nera, or of Terni, from that of the Tiber, and runs into the Tiber below the town of Todi, after a course of about 20 miles; 4, the Chiana, which is the outlet of the lake of Chiusi in Tuscany, drains the southern part of the Val di Chiana, receives the river Astrone on its right bank and the Tresa on its left, and entering the Papal territory near Città della Pieve, joins the Paglia at Orvieto, a few miles below which the united stream enters the Tiber.

The province of Perugia is the fourth in extent in the Papal State, being inferior only to those of Rome, Viterbo, and Spoleto e Rieti. It is the most fertile of the provinces south of the Apennines. The principal productions are corn, wine, oil, silk, and grass, on which large herds of fine horned cattle are fed: nearly one-half of the consumption of butcher's meat by the city of Rome is supplied by cattle from Perugia. The lake of Perugia abounds with fish, which forms a considerable article of export; and the shores are frequented by numerous aquatic birds. The climate is healthy, except in a few low spots on the banks of the lake and in the valley of the Chiana near Città della Pieve.

The principal towns of the province are—1, **Perugia**; 2, **Assisi**; 3, **Nocera**; 4, Foligno, a pleasant well-built town in a delightful valley on the river Topino, a short distance above its confluence with the Maroggia or Timia, which comes from Spoleto. Foligno is said to have been built about the eleventh century, being first inhabited by colonists from the antient town of Forum Flaminii, which was in the neighbourhood. It has a handsome cathedral, several other fine churches, and manufactures of woollens, silks, extensive paper-mills, and 7300 inhabitants. Foligno is one of the most trading inland towns in the Papal State. It suffered considerably from the earthquake of 1832. 5, Todi, the antient Tudertum, a city first of the Umbri, next of the Etruscans, and afterwards a Roman colony, stands on a hill above the Tiber. It has a cathedral and another handsome church built after the design of Bramante, with several remains of Etruscan and Roman antiquities, among which are the town walls and the ruins of a temple of Mars. The population of Todi is 2500. 6, Città di Castello, a well-built town, with 5000 inhabitants, in the valley of the Upper Tiber, near the borders of Tuscany, contains several fine churches, some good paintings, and the palace of the former baronial family of Vitelli, known in the history of the middle ages. It has a wooden bridge over the Tiber. 7, Città della Pieve, a small town situated on an eminence above the Chiana, has about 2000 inhabitants. Remains of antiquity have been dug up in the neighbourhood. (Brasavola, *Breve Ragguaglio della Città di Pieve*, folio, Perugia, 1686.) 8, Marsciano, a walled town in the valley of the Nestore, has about 2000 inhabitants, and a fertile territory. 9, Fratta, on the left or eastern bank of the Tiber, 14 miles north of Perugia, has some good buildings, a theatre, and a bridge on the river; the population, including its territory, is 4700. The inhabitants manufacture pottery, which they paint with considerable taste. 10, Castiglione del Lago, on the western bank of the lake of Perugia, has some good buildings, and about 5300 inhabitants, including the territory of the commune. 11, Gualdo, at the foot of the Apennines, 8 miles north of Nocera, is near the site of the antient town of Tadinum, long since ruined, near which Totila was defeated and wounded by Narses: it has about 4000 inhabitants. 12, Spello, a few miles north of Foligno, is on the site of the antient Hispellum, of which there are still considerable remains; among others, a triumphal arch in honour of the emperor Macrinus. Spello has several churches, with good paintings, a college, and about 2400 inhabitants. (Calindri, *Saggio geografico-statistico dello Stato Pontificio.*)

The province of Perugia is divided for administrative purposes into four districts, Perugia, Città di Castello, Foligno, and Todi, containing altogether 202,600 inhabitants (Serristori, *Statistica d'Italia*), and is one of the most interesting provinces of the Papal State, though little noticed by strangers.

PERUGIA, THE TOWN OF, built on a high hill which forms two summits, and rises on the left or western bank of the Tiber, is surrounded by walls in the form of a polygon. The streets are wide, and the squares are lined by massive old buildings. It has also numerous churches with lofty domes, fine gates, and retains all the appearance of an important though now somewhat decayed city. Perugia is a bishop's see, and it has a long-established university, which reckons among its early professors Bartolo and Baldo. The university is now attended by between

300 and 400 students: it has a library of 30,000 volumes, with some valuable MSS., among others a Stephanus Byzantinus, a botanical garden, a collection of minerals, and a cabinet of antiquities rich in Etruscan inscriptions, bronzes, vases, and medals. The academy of the fine arts has a collection of paintings by natives of Perugia and of the territory. Several noblemen have also galleries of paintings in their palaces, such as the Marquis Monaldi, Baron della Penna, Count Staffa, Oddi, &c. Perugia has a school of music, two theatres, a dramatic academy, a casino, or assembly-rooms of the nobility, and a literary cabinet or club. Perugia has long been distinguished among the provincial towns of the Papal State for its love of learning. A biographical list of authors natives of Perugia has been commenced by Professor Vermiglioli, 'Biographia degli Scrittori Perugini,' but not completed. Vermiglioli has also published a catalogue of writers who have illustrated the history of his native city: 'Biblioteca Storica Perugina,' 4to., Perugia, 1823. Oldoni has written 'Athenæum Augustum in quo Perusinorum Scripta publice exponuntur,' 1678. Passeri has written the lives of the native artists: 'Vite dei Pittori, Scultori, ed Architetti Perugini,' 4to., 1732. Brandolesi has given an account of the works published at Perugia in the first century of the invention of printing: 'La Tipographia Perugina del Secolo XV. illustrata,' 8vo., 1807. Vermiglioli has written on the mint of Perugia: 'Memorie della Zecca e delle Moneti Perugine,' 8vo., 1816. The antiquities of Perugia, both Etruscan and Roman, have been illustrated by Orsini, Vermiglioli, and Bianchini; and the modern works of art by Mariotti and Morelli, 'Pitture e Sculture della Città di Perugia,' 1683, besides the common guide-books. Among the contemporary learned men of Perugia, the antiquarian Vermiglioli, Mezzanotte (the translator of Pindar and professor of Greek literature), Canali (professor of physics and rector of the university), Colizzi (professor of law), and Antinori (a poet and professor of Italian literature), deserve notice. Perugia has produced two burlesque poets, Coppetta and Caporali, the latter of whom is considered by many as equal to Berni.

The population of Perugia, including the suburbs, is 15,000 (Calindri); in the time of its independence, in the sixteenth century, the population was reckoned at 40,000. The circumference of the walls is above six miles, but much of the area within is open and unbuilt upon. The citadel, from which there is a splendid view, extending on one side along the valley of the Tiber, and on the other over the basin of the lake, the plains beyond it, and the long chain of the Apennines, was built by Pope Paul III., to keep the city in awe, and it occupies a considerable space. Perugia has some manufactories of silks, woollens, and soap, but the principal trade consists in the products of its fertile territory, corn, oil, wool, and cattle.

Among the many churches of Perugia, said to be above one hundred, the most remarkable are—1, the Duomo, or cathedral, in the Gothic style, with some good paintings by Signorelli, Baroccio, and others. A painting by Perugino, representing the marriage of the Virgin, which adorned this church, was taken away at the first invasion of Bonaparte, and it is not known what has become of it. The number of masterpieces of paintings taken from Perugia by the French amounts to about thirty. Some were restored at the peace, but it seems that, instead of returning to Perugia, they have been placed in the Vatican gallery at Rome. 2, The church of S. Francesco was plundered of the 'Descent from the Cross,' by Raphael, at an earlier date, by Paul V., and this picture is now in the Borghese Gallery. 3, The vast Benedictine convent of S. Pietro, one of the wealthiest in the Papal State, has several paintings by Vasari. 4, The church of S. Domenico has a fine coloured-glass window in the choir, and the tomb of Pope Benedict XI., who died at Perugia in 1304, is remarkable for its sculptures. Descriptions of each of these churches are published.

The town-house, 'Palazzo dei Priori,' a vast Gothic building, and the residence of the delegate and of the municipal authorities, contains the archives of Perugia, among which are some curious documents of the middle ages. The old exchange, 'Sala del Cambio,' is adorned with beautiful frescoes by Perugino. The square before the cathedral contains a beautiful fountain, with sculptures by Giovanni da Pisa. In the square 'Del Papa' is the bronze statue of Julius III. seated in a chair, cast by Vincenzo Danti of Perugia. The Place Grimana has a handsome gate, said to be of Etruscan construction, but called the arch of Augustus. The church S. Angelo is built on the site and with the materials of an antient temple. For the Etruscan remains at Perugia, see Etruria (*Antiquities*).

Some interesting excavations are now going on at Perugia, and many objects of antiquity have just been discovered in the immediate vicinity of the city while making a new road. (*Communication from Perugia*, Jan., 1840.)

Perusia was one of the principal cities of antient Etruria, but it seems to have been built before the Etruscan dominion by a colony of Umbri from Sarsina. (Servius, x. 201.) In an Etruscan inscription in the Museum Oddi it is called Perusei. Perusia acted a principal part in the wars of the Etruscans against Rome; its troops were defeated by the consul L. Fabius Maximus, and then Perusia, together with Arretium, sued for peace, and paid tribute to Rome, 294 B.C. (Livy, x. 31, 37.) In the second Punic war, Perusia was one of the allied towns that sent timber and provisions to Scipio to fit out his armament against Africa. During the second triumvirate, the consul Lucius Antonius, brother of Marcus the Triumvir, stimulated by Fulvia, his sister-in-law, having quarrelled with Octavian, and being defeated, shut himself up in the town of Perusia, where he sustained a long siege, and at last, through famine, was obliged to surrender to Octavian, who put to death 300 of the principal citizens of Perusia, and gave up the town to plunder. Perusia was on that occasion nearly destroyed by fire. It was afterwards rebuilt under the name of Perusia Augusta. At the fall of the Western Empire, it was devastated by the Goths under Totila. It passed afterwards through the same vicissitudes as most other towns of Italy: it ruled itself for a time as a free municipality, had its factions of Guelphs and Guibelines, its own tyrants, and at last submitted voluntarily to the rule of Braccio da Montone, one of the best and wisest chieftains of the middle ages. After his death, the government passed through the hands of several of his relatives, and from them to that of the family of Baglioni. Giovani Paolo Baglioni, being seized at Rome by Pope Leo X., was beheaded on some political charge. His descendants however governed Perugia for some years after, until Pope Paul III. united it to the Papal State and built the citadel. (Ciatti, *Memorie di Perugia;* Mariotti, *Saggio di Memorie Istoriche della Città di Perugia.*)

Twelve miles north of Perugia, in a romantic situation among the Apennines, is the monastery of Monte Corona, belonging to the order of Camaldoli, the monks of which have cultivated and planted with trees the surrounding territory. This monastery was one of the few that was spared by the French during their occupation of the Papal State. The monks have an hospice at the foot of the mountain for the reception of travellers. (Premuda, *La Istoria Romoaldina, ovvero Eremitica di Monte Corona*, Venice, 1590.)

PERUGI'NO, PIETRO, or PIETRO VANNUCCI DELLA PIEVE, 'DE CASTRO PLEBIS,' was the son of a certain Cristofano, a poor man of Castello della Pieve, where Pietro was born, in the year 1446. His father is said to have placed him as a shop-boy (fattorino) with a painter of Perugia. When about twenty-five years of age he visited Florence, and, according to Vasari, became a pupil of Andrea Verocchio, the master of Lorenzo di Credi and Leonardo da Vinci; but this fact seems very doubtful. In the course of a few years he attained considerable reputation, and his works were so much esteemed as to be exported. In 1475 we find him employed by the magistrates of Perugia, and the order for a payment to him in that year appears on the public records of the town. In 1480 he executed some frescoes for Sixtus IV. in the Sistine chapel at Rome: only one or two of these now remain, the greater part having been destroyed to make room for the Last Judgment of M. Angelo in the time of Paul III. The Dead Christ, and other figures so much praised by Vasari, were painted for the nuns of Santa Chiara at Florence in 1485. Francesco del Pugliese is said to have bid for this picture three times the original price, and a duplicate by Perugino, but the offer was refused. In the year 1500 Pietro executed the frescoes in the Cambio at Perugia. He afterwards visited Florence again, but, in consequence of a quarrel with the artists there, returned to the city whence he derives his name. He died at Castello della Pieve, in 1524.

The fame of Perugino has certainly been widely spread, from the circumstance of his having been the teacher of Raphael; but, at the same time, the superior genius of the pupil has thrown into comparative obscurity the real merit of the master. Perugino was a most unequal painter: his early works are far better than those executed after 1500. The popularity of his pictures, and the facility which he had acquired, produced repetition and mechanical execution. Vasari says 'he gave all his figures one and the same air;' it must however be admitted that that 'air' is far superior to the contortions of Vasari himself and his fellow-pupils in the school of M. Angelo. Perugino lived to see the conflict between the old and simple style and the very different principles of the great master just named. With M. Angelo himself he is reported to have had a public quarrel: Vasari's account therefore of his moral character must be received with some little suspicion. He says that Perugino was an infidel, who could never be brought to believe in the immortality of the soul, and who would do anything for money. At the same time he gives him great credit for his technical skill, especially in colouring.

Among the best pictures of Perugino now extant are:—An Infant Christ, Virgin, and Angels, painted in 1480, and preserved in the Albani Palace at Rome; a Fresco in Santa M. Maddalena dei Pazzi at Florence, executed at a later period; the Dead Christ, before alluded to (now in the Pitti Palace, No. 164); one or two pictures in the Accademia at Florence; and his frescoes in the Cambio at Perugia. Mr. Beckford, in this country, possesses a work of Perugino's best time.

Raphael was a pupil of Perugino, and his early works, such as the Marriage of the Virgin, greatly resemble those of his master. [RAPHAEL.]

The following painters were among the most eminent scholars of Perugino:—Pinturicchio of Perugia; Andrea Luigi d'Ascesi, called l'Ingegno; Giovanni Spagnuolo, surnamed Lo Spagna; and Rocco Zoppo of Florence.

(Vasari, *Vite dei Pittori;* Rumohr, *Italienische Forschungen;* Lanzi, *Storia Pittorica.*)

PERU'SIA. [PERUGIA.]

PERUVIAN ARCHITECTURE. [PERU.]

PERUVIAN BARK. [CINCHONA.]

PERUZZI, BALDASSA'RE, an architect of less celebrity than many greatly inferior to him in design, was born in 1481, at Volterra, to which city his father Antonio had removed, in order to avoid the civil dissensions which agitated Florence. A few years afterwards Volterra itself was besieged and sacked, and Antonio fled to Siena, where the family lived in reduced circumstances, having lost nearly all their property. On his father's death, Baldassare, who had enjoyed opportunities of access to many artists and their works, determined to apply himself to painting, which he did with so much assiduity, both from his natural inclination and from his wish to aid his mother and sister, that he made extraordinary progress. After executing some subjects in a chapel at Volterra, he accompanied a painter of that city, named Piero, to Rome, where the latter was employed by Alexander VI. The death of that pope frustrated their scheme of working in concert at the Vatican; however Baldassare remained for awhile at Rome, where he painted some frescoes in the church of S. Onofrio, and in that of San Rocco à Ripa, and distinguished himself by some others at Ostia, particularly by one in chiaro-scuro, representing a siege by Roman warriors, and remarkable for the strict fidelity of the antient military costume, which he derived from bas-reliefs and other existing monuments.

On returning to Rome he found a liberal patron in the celebrated Agostino Chigi (a native of Siena), by whom he was enabled to continue at Rome for the purpose of devoting himself chiefly to the study of architecture. The acquirements he thus made soon displayed themselves in what was then quite a new career of art, namely architectural perspectives and scene-painting; and the science of perspective and its application to pictorial illusion and effect. To what perfection he brought this branch of art may be judged from what Vasari relates, who says that on his taking Titian to see some of Peruzzi's works, that great painter could hardly believe at first that the objects were not real. Of his astonishing performances in scene painting there is now no evidence, but some idea of his extraordinary ability in it may still be formed from the painted architecture, &c. with which he decorated a gallery in the Farnesina. It was not however in scenic and fictitious architecture alone that he displayed his talent for that art; he designed many elegant façades at Rome, and gave proof of his superior ability in the Palazzo Massimi, one of the most original and tasteful edifices of its class in that city. Instead of being perplexed by the awkwardness of the site, he availed himself of it to curve the front of the building, and thereby produce so happy an effect that such form seems to have been entirely the result of choice, and independent of other circumstances. The loggia and small inner court are singularly beautiful, and the whole edifice deserves the attention it has received in a folio work, by Suys and Haudebourt, expressly devoted to it, and containing outline engravings of all its parts and details (Paris, 1818).

Peruzzi made a design for St. Peter's on the plan of a Greek cross, which, had it been executed, would have surpassed the present structure; also two different designs for the façade of S. Petronio at Bologna. On Rome being taken and sacked by the Constable Bourbon, it was with extreme difficulty that Baldassare escaped from the hands of the soldiery, and after being pillaged of everything, reached Siena, where he was most kindly received, and employed on various buildings. He returned however to Rome, and it was then that he built the Palazzo Massimi, but did not live to see it quite completed. He died in 1536, not without suspicion of having been poisoned by a rival who sought to obtain the appointment which he held as architect of St. Peter's. He was buried in the Pantheon, near Raphael.

PE'SARO E URBI'NO, LEGAZIONE DI, a province of the Papal State, is bounded on the east by the province of Ancona, on the north and north-east by the Adriatic Sea, on the west by the province of Forli and the grand-duchy of Tuscany, and on the south by the province of Perugia. The area is estimated at 1749 square miles. (Neigebaur.) The central ridge of the Apennines, which divides the province of Pesaro e Urbino from Tuscany, projects eastward towards the Adriatic in the neighbourhood of Urbino, and sends off several offsets, which run to the sea-coast, forming the natural boundary between Northern and Southern Italy. The mountain on which San Marino stands forms part of one of these offsets. [SAN MARINO.] Several streams run in a north-east direction from the Apennines to the sea. The first of these streams, reckoning from the north, is the Conca, which runs along the boundary between the province of Forli and that of Pesaro, and after a course of about twenty-five miles enters the sea near La Cattolica. The next is the Foglia, the antient Pisaurus, which rises in the Apennines of Carpegna on the Tuscan border, and after a course of forty-six miles enters the sea at the town of Pesaro. Farther south is the Metauro, the largest river in the province, which rises near Borgo Pace on the east side of the Apennines that bound the valley of the upper Tiber: it runs first due east, passing by the towns of St. Angelo and Urbania, receives the united stream of the Cantiano and Candigliano, which comes from the south from the mountains of Gubbio, then turning to the north-east passes by Fossombrone, and enters the sea by the town of Fano, after a course of nearly sixty miles. According to a tradition among the country-people, the spot in which Hasdrubal was defeated and killed is a plain called Piano di San Silvestro, above the confluence of the Cantiano, and about six miles south of the town of Urbino. A tower on a hill called Monte d'Elce, on the right bank of the Metaurus, is called the sepulchre of Hasdrubal. The Flaminian road from Fano crosses the Metaurus above Fossombrone, and follows the course of the Cantiano, ascending the Apennines above the source of the latter river, and afterwards descending by Gualdo to Nocera. The next river in the province of Pesaro is the Césano, which rises in the mountains of Avellana, passes the town of Pérgola and the site of the antient town of Suasa, of which some remains are still visible, and enters the sea north-west of Sinigaglia, after a course of about thirty miles. South-east of the Césano is the Misa, which enters the sea at Sinigaglia, after a course of about twenty-five miles.

The surface of the province of Pesaro e Urbino is hilly; some parts of it are very fertile, but the mountains are generally barren. The lower hills are planted with vines, olive, and mulberry-trees. Good pasture is also abundant. The province is divided into five districts—Urbino, Pesaro, Fano, Sinigaglia, and Gubbio, containing altogether 226,000 inhabitants. (Serristori.) The principal towns are—URBINO, which is the old capital of the province and the residence of the former dukes. 2. Pésaro, the antient Pisaurum, a well-built town and a bishop's see, has several fine churches with some good paintings, a fine market-place, several palaces of the nobility, and the palace of the former dukes della Rovere, who were once sovereigns of this little state, a public library of 15,000 volumes, with a museum and a cabinet of models bequeathed by Olivieri, a learned man of Pesaro, to his townsmen. Pesaro has a small harbour, several manufactories of silks, pottery and glass, and leather, and about 11,000 inhabitants. (Calindri.) The surrounding territory, which is very fruitful, produces, among other things, excellent figs, and is covered with pleasant country-houses. Pesaro carries on a considerable trade in the agricultural products of the province. A bed of coal has been discovered in the neighbourhood. Pesaro has a civil and criminal court, and a commercial tribunal, a college, and a clerical seminary. It is the birth-place of Pandolfo Collenuccio, a chronicler and poet of the fifteenth century; of Count Perticari, a philologist and son-in-law of Monti; and of the musical composer Rossini. 3. Fano, the antient Fanum Fortunæ, is a town with about 7000 inhabitants. It has a triumphal arch dedicated to Augustus, which has been badly restored, and therefore spoiled (Poletti, *Ragionamento intorno all' Arco d'Augusto in Fano*), several churches with paintings by Guido and Guercino, a handsome theatre, some silk manufactories, and a public library. On the coast near Fano are taken great quantities of a small fish called 'cavallo marino,' the head of which resembles that of a horse, and has a sort of mane attached to it. 4. Sinigaglia, the antient Sena Gallica, is a bustling town with a small harbour, several churches and convents, and about 8000 inhabitants. It is chiefly remarkable on account of its great fair, one of the largest in Italy, which is held in the month of July, and is frequented by tradespeople from all parts of Italy, and also from other countries. About 200 vessels, mostly of small burthen, of the various nations which trade in the Mediterranean, arrive at Sinigaglia at that time, and bring colonial and other produce, and also French, English, and German manufactures. The celebrated singer Madame Catalani, was a native of Sinigaglia. 5. Fossombrone, situated on a hill about a mile and a half from the ruins of Forum Sempronii, which are lower down the banks of the Metaurus, is a bishop's see, has several churches and convents, a bridge on the Metaurus, and about 4000 inhabitants. The silk spun at Fossombrone is considered the best in Italy. 6. Gubbio, the antient Iguvium, a city of the Umbri, is situated out of the high road on the southern slope of the Apennines near the sources of the Chiascio, an affluent of the Tiber: it has several churches and other buildings worthy of notice, and about 4500 inhabitants. Old Iguvium was in a lower situation than the present town; the amphitheatre is still in tolerable preservation; eighteen of the lower arches are remaining, as well as three of the upper row. There is also an antient tomb, with other remains of antiquity. No traces of the temple of Jupiter Apenninus, an old deity of the Umbri, are visible at Gubbio, but according to Micali, they are to be seen three miles from Chiascerna, the antient Clavernium, not far from the post station of La Scheggia in the Apennines, on the high road called the Furlo. In this neighbourhood also were found, about the middle of the fifteenth century, the seven bronze tablets written partly in Etruscan and partly in Latin characters, and known by the name of the Eugubine tables, which are now in the museum of Gubbio. According to the interpretation of Lanzi, they relate entirely to the religious rites of the antient Umbri. 7. Cagli, the antient Callis, a Roman colony, on the Flaminian road, has about 3000 inhabitants, and some remains of antiquity. 8. Urbania, a modern town, which derives its name from pope Urban VIII., is situated on the banks of the Metaurus, has a collegiate church, a manufactory of majolica, or Delft ware, and about 4400 inhabitants. 9. Pérgola, on the Césano, has 2500 inhabitants. [Calindri.]

The province of Pesaro e Urbino is very interesting for its romantic scenery, its classical recollections, and the numerous remains of antiquity which are scattered about it.

PESCE, NICOLA, or COLA, a famous Sicilian swimmer and diver, who lived towards the end of the fourteenth century. His name was Nicholas, and he was surnamed 'Pesce' (the fish) on account of his expertness in diving. Frederic II., king of the Two Sicilies, employed him, and encouraged his feats. The most incredible stories are told of him; it is said that he passed whole hours under water, and whole days in the water; that he used to swim from Sicily to the Lipari Islands, carrying letters and despatches in a leathern bag, &c. The truth seems to be that he was a most expert swimmer and diver, and that he could remain longer under water than any other person on record. He had been accustomed from his boyhood to dive for oysters and coral along the coast of his native country. It is reported that king Frederic once asked him to dive into the sea off the Point of Faro, where the current forms a whirlpool known by the name of Charybdis; and as Pesce hesitated, the king threw a golden cup into the sea, when Pesce plunged in, and after remaining a considerable time under water, brought up the cup, to which the king added a purse of gold as a gift. Pesce was induced to repeat the experiment, but he never rose again from the sea. (Kircher, *Mundus Subterraneus*, b. i.) We know now that the whirlpool of Charybdis is not so fearful as it was once represented to be, and that at times there is very little agitation in the water.

Mariotti, in his 'Riflessioni' on the lake of Perugia, speaks of a fisherman called Nonno di San Feliciano, who was 'a great swimmer and diver, like Pesce Cola of Sicily and lived almost entirely in the water. He lived till past ninety years of age.' It must be observed however that the lake of Perugia is not very deep.

PESHAWER. [AFGHANISTAN.]

PESTH, the greatest commercial town and the most populous city in Hungary, is situated in 47° 30′ N. lat. and 19° 4′ E. long., on the left or east bank of the Danube, about 20 miles from the spot where the course of the river, till then nearly from west to east, makes a sudden bend to the south. On the other side of the Danube, which is here about 1500 feet broad, is the city of Ofen. [BUDA.] The two cities are connected by a bridge of boats, which, including the fixed portion on the two banks, is 1500 paces in length. The city of Pesth is about seven miles in circumference. It consists of five principal parts—1, the old town, which, though antiquated and irregularly built, contains some fine buildings; 2, the Leopoldstadt, or new town; 3, the Theresienstadt; 4, the Josephstadt; and 5, the Franzstadt—so named after the sovereigns in whose reigns they were built. Leopoldstadt is now joined to the old town, the walls which formerly surrounded the latter having been levelled to make room for new buildings. Leopoldstadt is built on a very regular plan. The other three parts or suburbs are separated from these two by a very broad street. Among the fifteen churches, that of the university is distinguished by its fine steeple and excellent fresco paintings. The other Roman Catholic churches, 11 in number, are not remarkable; but the Greek church on the Danube is one of the finest buildings in the city. The two Protestant churches are very plain edifices. Of the other public buildings, the following deserve notice: the great barracks built by Charles VI.; the hospital of invalids, an immense edifice begun in 1786 under Joseph II., the building of which was interrupted by the Turkish war (it is not known to what use it was destined by that emperor; at present it serves as barracks for a regiment of artillery); the theatre, a very handsome edifice, capable of containing 3000 spectators; the national museum, and the university. The university was founded in 1635 at Tyrnau. In the seventeenth and eighteenth centuries it exercised, through the powerful agency of the Jesuits, great influence over the people. In the year 1777 it was transferred by Maria Theresa to Ofen, and in 1784 by Joseph II. to Pesth. The branches of learning taught are theology, law, medicine, philosophy, philology, and mathematics. There are 49 professors and above 1000 students. The university has a library of 60,000 volumes, a cabinet of natural history, a collection of medals, a chemical laboratory, and an anatomical and pathological collection. Dependent on it are the botanic garden, the veterinary school, the university hospital, and the observatory at Ofen, which stands on the Blocksberg, 278 feet above the Danube, and is well furnished with good instruments. The National Museum, which is independent of the university, was founded by Count Szecsenyi, who gave his fine library and a valuable collection of Hungarian coins and medals, and induced the Diet in 1808 to endow it. It would take a volume to describe this museum. The collection of coins and medals contains above 60,000 specimens, of which the Greek, Roman, and other antique silver medals amount to above 12,000. The gymnasium of the Piarists has 800 scholars; and the city normal school (likewise in the convent of the Piarists), above 400. There are eight other Catholic schools, two Greek, and two Protestant schools. The Roman Catholic girls' school of the English ladies, as it is called, has 400 day-scholars and 40 boarders.

Though Buda is the residence of the viceroy and the capital of the kingdom, Pesth is the seat of the high court of justice, and of the supreme court of appeal and other tribunals, and also of the government of the three united counties of Pesth, Pils, and Solther, which contains a population of 400,000 inhabitants. The manufactures are of silk, cotton, leather, jewellery, and musical instruments, but on a small scale; that of tobacco is a government monopoly. Pesth however has, next to Vienna, the greatest trade of any city on the Danube. It has four fairs, each of which lasts a fortnight. The principal articles sold are manufactures and colonial produce, and the natural productions of the country, such as cattle, wine, wool, tobacco, and raw hides, honey, wax, &c. Above 14,000 waggons and 8000 ships are employed in conveying goods to and from the fairs, the value of which at each of them is from 16 to 17 millions of florins. The environs of Pesth are not picturesque, the city being situated on a sandy plain, but there are some fine promenades, such as the Grove, a mile and a half from the city; the gardens of Baron Orczy; and the Palatine, or Margaret Island, in the Danube, which is laid out in walks and gardens with great taste. Among the inhabitants are many noblemen, country gentlemen, professors, judges, and lawyers. The population of Pesth consisted (1833) of 62,850 inhabitants, of whom about 54,000 were Roman Catholics, 3000 Protestants, 817 Greeks, and 5000 Jews. With the addition of the garrison (9133 men) and the numerous strangers, the population amounts to 75,000. Pesth, though an antient town, is in its present form comparatively recent. It has been frequently laid waste by war, and was in the possession of the Turks for nearly 160 years, who were not finally expelled till 1686. Civil war followed, and at the beginning of the eighteenth century Pesth was one of the most inconsiderable towns in the kingdom. Its improvement may be dated from the reign of Maria Theresa, and it has since been progressive and rapid. In 1793 there were only 2580 houses: there were in 1837, 4500. The winter of 1838 was disastrous to Pesth, above 1200 houses being destroyed by the overflowing of the Danube. They were however, for the most part, the worst buildings in the city, and there is little doubt that the spirit of the inhabitants, aided by the munificent contributions sent to them from all parts of the empire, will in a few years efface all traces of the devastation.

(J. v. Thiele, *Das Königreich Ungarn*, vol. vi.; *Oesterreichische National Encyclopädie*; R. E. v. Jenny, *Handbuch für Reisende in Oesterreich*; Blumenbach, *Gemälde der Oesterreichischen Monarchie*.)

PESTILENCE, or PLAGUE, is a disease of so fatal and malignant a nature, that to this very circumstance it probably owes its nomenclature; but some misapprehension exists as to its definite character, and this has originated from writers having applied the terms pestilential and pestilent in a generic sense to diseases specifically different; hence we read of pestilential small-pox, pestilential cholera, &c. In fact every virulent and contagious disease may be called pestilent, but every pestilential disease is not plague. In casting a glance over the histories of these epidemics, it is obvious that many things are involved in obscurity. Numerous facts have however been collected, and are agreed upon by all parties, and we shall endeavour, by a comparison of these, to arrive at some definite conclusion as to the nature of plague. The nosological definition of this disease by Dr. Cullen is perhaps as correct as can be given in few words:—'A typhus fever, in the highest degree contagious, and accompanied with extreme debility. On an uncertain day of the disease, there is an eruption of buboes or carbuncles.' Dr. Patrick Russell, who practised at Aleppo during the plague of 1760-1-2, informs us that its progress at its commencement is much the same in the several parts of the Levant as in the cities of Europe. It advances slowly, fluctuating perhaps for two or three weeks; and although at that period it generally proves fatal, yet it is often unattended by its characteristic eruptions. Indeed the cases in which the eruption is wanting constitute the most rapidly fatal type of the disease. The general derangement of the system which ushers in an attack of the plague, is much like that which commences the course of ordinary fever. A sense of cold, with some shivering, which is soon followed by heat and acceleration of the pulse, with giddiness, headache, depression of strength and spirits, white tongue, vomiting or diarrhœa, and great oppression about the præcordia, are among the first symptoms of the disease. These are succeeded by a burning pain about the pit of the stomach; by a peculiar muddiness of the eyes; by coma, delirium, and other affections of the sensorium, which terminate by death in some cases on the second or third day, before the pathognomic symptoms, buboes and carbuncles, have appeared. In other cases these last-mentioned symptoms are present, together with purple spots and ecchymoses, which belong to the plague in common with other malignant fevers. Though these are the ordinary symptoms of plague, they are not all invariably observed in the same individual; but many varieties occur, which chiefly have reference to the greater or less virulence of the disease, and the absence or presence of some particular symptoms. Thus, we are informed by Sydenham that in the infancy of the great plague of London scarce a day passed but some of those who were seized with it died suddenly in the streets, without having had any previous sickness; the purple spots, which denote immediate death, coming out all over the body, even when persons were abroad about their business; whereas after it had continued for some time, it destroyed none, unless a fever and other symptoms had preceded. Dr. Russell describes six classes or varieties of plague, in some of which the fever appears to have been very violent, while in others it was proportionally mild. The most destructive forms of the disease, according to this author, were marked by severe febrile symptoms; and the infected of this class seldom or never had buboes or carbuncles. The bubo however was the most frequent concomitant afterwards; carbuncles, on the contrary, were remarked in one-third of the infected only, and were seldom observed at Aleppo earlier than the month of May, near three months after the disease began to spread. The carbuncle increased in the summer, was less common in the autumn, and very rarely was observed in the winter. The absence of bubo and carbuncle at the commencement of the plague has been one of the grounds of contention among writers as to the real nature of the disease. Diemerbroech and some others assure us that no one symptom is pathognomonic of plague, and Dr. Russell concludes that 'the plague, under a form of all others the most destructive, exists without its characteristic symptoms, can admit of no doubt.' From all the evidence upon this subject that we have been able to collect, it plainly appears that authors are by no means agreed on the existence of the plague as a distinct disease. The symptoms, morbid changes, history, and mode of propagation of plague, bear so close a resemblance to those of the malignant typhus of this country, that it is difficult to regard them otherwise than as types of the same disease. This opinion is strengthened by the authority of Dr. Mackenzie, who resided thirty years at Constantinople. 'The annual pestilential fever of that place,' he observes, 'very much resembles that of our gaols and crowded hospitals, and is only called plague when attended with buboes and carbuncles.' Sir John Pringle too observes, 'that though the hospital or gaol fever may differ in species from the true plague, yet it may be accounted of the same genus, as it seems to proceed from a like cause, and is attended with similar symptoms.' The buboes which characterise plague consist of inflammatory swellings of the glands in the groin and armpits; the parotid, maxillary, and cervical glands sometimes, but less frequently, become affected. These buboes may either suppurate or gradually disperse: when suppuration occurs, it is seldom till the fever has begun to abate, and is manifestly on the decline, as about the eighth or ninth day. Carbuncles consist of inflamed pustules or angry pimples, which, instead of suppurating, frequently terminate in mortification. They may be seated on any part of the body. The morbid changes that are met with in the bodies of those who die from plague are very similar to what we find in typhus, yellow fever, and in the carcasses of animals that have died in consequence of a putrid matter injected into their veins. The vessels of the brain and its membranes are gorged with a dark coloured blood; the lungs and liver present traces of inflammation or of gangrene; patches of inflammation and ulceration are met with in the stomach and intestines; the heart is of a pale red colour, easily torn, and full of black blood, which, according to M. Magendie, never coagulates. These changes however are not always found, and the same absence of appreciable organic lesion is sometimes observed in typhus and other diseases which prove rapidly fatal. No age, sex, or profession appears to enjoy an immunity from plague, nor does one attack secure the individual from future infection;

but it has been observed that old persons, women, and children suffer less frequently and severely from its attacks than robust adults. Some persons also, who exercise particular trades, as knackers, tanners, water-carriers, bakers, and oilmen, seem to share this advantage; while smiths and cooks were noticed, during the campaign in Egypt, to be more particularly liable to it. One law appears to be universal in all plagues, namely, that the poor are the first and chief sufferers. In Grand Cairo, Constantinople, and Aleppo, it is in the low, crowded, and filthy parts of those cities, occupied by the poorest people, that the plague commits its greatest ravages. The celebrated plague of Marseille, in the year 1720, first appeared in a part of the city noted for the sordid filth, crowded state, and wretchedness of the poor inhabitants. This was likewise true of London, where, from the same circumstance, it obtained the appellation of the Poors' Plague. Like many other diseases, plague is observed in two forms: first, as an indigenous and local disease, peculiar to the inhabitants of certain countries, and from which they are never entirely free; and secondly, as a raging and fatal epidemic, not confined to its original seat, although exhibiting itself there in its most intense forms. It is the epidemic variety of this fatal malady that has engrossed so much attention from the earliest times down to the present; and we shall therefore briefly pass in review some of the principal circumstances which attend its origin, progress, and termination.

It has been observed that nearly all plagues have been preceded by certain natural signs, and by a greater mortality from malignant diseases generally than at other times. Among these precursory signals great and sudden atmospheric vicissitudes have been noted. Livy (v. 13) attributes the origin of a pestilence to this cause. 'The year was remarkable,' he observes, 'for a cold and snowy winter, so that the roads were impassable and the Tiber completely frozen. This deplorable winter, whether it was from the unseasonable state of the air, which suddenly changed to an opposite state, or from some other cause, was succeeded by intense heat, pestilential and destructive to all kinds of animals.' But in the great plague of Athens, of which Thucydides has given so minute a description (ii. 48, &c.), he observes that the year of the plague was particularly free from all other diseases; and he mentions nothing unusual as having occurred in preceding years. The city however was then greatly over-crowded with inhabitants, a great part of the population having taken refuge within the walls of Athens (ii. 16), in consequence of the war. [PERICLES.] Russell informs us that the winter of 1756-7, which preceded the petechial fever of 1758 at Aleppo, and the plague of 1759-60-1-2 in different parts of Syria, was excessively severe. Olive-trees which had withstood the weather for fifty years were killed. In the following summer a dearth ensued from the failure of the crops, and so severe a famine, that parents devoured their own children, and the poor from the mountains offered their wives for sale in the markets to buy food. The connection between famine and pestilence has been noticed in all ages of the world. An enormous increase of insects has frequently been observed to precede a pestilence. We are informed by Short, that in 1610 Constantinople was infested with crowds of grasshoppers of great size that devoured every green thing, and the next year (1613) the plague carried off 200,000 inhabitants of that city. In 1612, swarms of locusts laid waste the vegetable kingdom in Provence; and 1613 the plague appeared in different parts of France. Locusts and pestilence are frequently mentioned together in the sacred writings; and we find that the plagues of Egypt exhibited a series of phenomena, rising in progression from corruption of the rivers and fountains, swarms of insects, murrain among cattle, thunder and thick darkness, and a tribe of inferior diseases, to that fatal pestilence which swept away the first-born of the Egyptians. In fine, dearth or unwholesome provisions, pestilence among cattle, great abundance of insects, absence or death of birds, blight and mildew, appear, with few exceptions, to have separately or conjointly preceded or attended all such calamities. Plague is usually preceded by other diseases which occasion great mortality. Lord Bacon has observed that 'the lesser infections of small-pox, purple fever, agues, &c., in the preceding summer and hovering all winter, do portend a great pestilence the summer following; for putrefaction rises not to its height at once;' and Dr. Mead states, as a general fact, that fevers of extraordinary malignity are the usual forerunners of plague. Indeed nearly all the most remarkable plagues of the last two centuries have been preceded by malignant fevers. The increased number of deaths from this source will be seen by an examination of the London Bills of Mortality at the three last plague epochs in this country, an abstract from which we here present, showing the number of deaths from other diseases besides the plague, in 1625, 1636, and 1665, with that of the year before and after respectively:

Years.	Common Diseases.	Plague.
1624	12,199	11
1625	18,848	35,417
1626	7,400	134
1635	10,651	..
1636	12,959	10,400
1637	8,681	3,082
1664	18,291	6
1665	28,710	68,596
1666	10,840	1,998

The season of the year in which pestilence commits its greatest ravages differs in different countries. In Europe it has invariably raged most violently and fatally in the summer and autumnal months, especially in September. Thus, in the plague of London in 1665, the deaths from the plague were: in June, 590; in July, 4129; in August, 20,046; in September, 26,230; in October, 14,373; in November, 3449; and in December they were under 1000. In Egypt it commences in the autumn, and prevails till the beginning of June, and the vernal equinox is the period of the greatest fatality. Extremes of heat and cold generally check and not unfrequently entirely arrest its progress. In tropical climates the disease is unknown, and in Egypt, according to Alpinus, to whatever degree pestilence may be raging, as soon as the sun enters Cancer it entirely ceases. The cold weather of northern climates has been observed to check the ravages of plague; and in these countries when it has broken out in the autumn, its course has been arrested during the winter months. With respect to the progress and termination of plague, the disease appears to be subject to the same laws as regulate the course and termination of other epidemics: it is most fatal at its first outbreak, and becomes less virulent as it increases in extent. The increased mortality which occurs during the advance of plague, and which we have before shown to be at its height in the month of September, arises from the increased extension and not from the greater malignancy of the disease. With its progress and decline there has usually been observed a progressive increase and decrease in the whole train of diseases, and those which had immediately preceded plague, on its decline reappeared. The former fact will be seen by a reference to the table we have given above.

The causes of pestilence have been referred by some to a vitiated atmosphere, engendered by epidemic and endemic causes, and wholly independent of contagion; while others have attributed it solely to the latter influence. The truth probably lies between these extremes, and we have little doubt, from an examination of the evidence on both sides of the question, that both these causes do occasionally operate in the propagation of plague. As the foundation of quarantine establishments rests entirely on the supposition of the contagious nature of plague, we shall examine how far this can be supported by a reference to facts. It is asserted by the contagionists that plague is transferred from individual to individual in all the ascertained modes in which diseases are thus communicated—by contact, by inoculation with the matter of buboes, through the atmosphere, and by fomites. According to them, its appearance in Western Europe has been always owing to imported contagion; and where strict isolation from all infected individuals and articles has been observed, there it has never appeared. It is admitted however by several, among whom may be mentioned the respected names of Sydenham, Russell, and Mead, that a peculiar atmospheric condition is essential to the spread of pestilence; yet they maintain that this is inadequate to its production without importation by fomites, or the arrival of a diseased person from an infected district. In support of this opinion, they refer to the histories of the different plagues that have visited Europe, and above all to that which ravaged Marseille in the year 1720. Its introduction into this city was traced to the arrival of three ships or lazarettos, which, by some means or other, for we learn not how, communicated the disease to a woman living in the Rue de l'Escale. This person being received into the Hôtel Dieu, two of the nurses who assisted at her reception, and the matron who changed the linen, were taken ill the next day, and died after a few hours. In a short time it destroyed physicians, surgeons, apothecaries, confessors, and all the other officers and servants, with the whole of the poor in the hospital, including above 300 foundlings. The priests and monks who attended the infected, suffered in the same manner as the medical assistants: and lastly, of 230 galley-slaves, employed in going into the infected houses and burying the dead, 220 perished in the space of ten or twelve days. Many of these facts however may be not inaptly termed false facts; and some, of undoubted existence, that are brought forward as examples of contagion, may be explained on another hypothesis. It is admitted by all that animal effluvia, from a number of persons crowded into a small space, and surrounded by their own filth, acquire a high degree of virulence, even without the morbid action of a febrile affection. If then, to the circumstances above noticed, are superadded corrupt food and the influence of a sickly season, is it surprising that miasmata endowed with a most pestilential contagious power should be generated? But this rapid transit of plague from one individual to another is only what we know to take place in other epidemic diseases. To illustrate this position by a familiar and well-known disease—epidemic catarrh, or influenza: what is more common than for all the members of a family living together, the clerks in the same office, and the artisans of the same workshop, to be successively or almost simultaneously attacked? Yet nobody attributes the circumstance to contagion: certainly, if one had a motive for so doing, nothing would be easier than to accumulate examples without number in support of this position. Whatever share then contagion may have in the propagation of the plague, it is quite certain that its power has been greatly overrated. According to the most staunch supporters of this doctrine, a particular state of the air is essential to its action; and they all admit that whenever the plague has been excited out of its proper season, it has not spread. Without being understood to advocate the contagious origin of plague, we fully agree with Dr. Bancroft that 'it is fortunate for mankind that the communication of the contagion of the plague depends upon the co-operation of so many favourable circumstances, and particularly upon that of a suitable temperature, and of certain aptitudes and susceptibilities in the human subject; for without such requisites, or such obstacles to its propagation, the earth might have long since become desolate.' Those who contend for the non-contagiousness of plague, and therefore for the abolition of the quarantine laws, maintain that these laws, however strictly enforced, have not succeeded in shutting out the plague from pestilential districts; and that countries not possessing indigenous sources of pestilence are not visited with this disease, although unprotected by quarantine establishments. They likewise adduce numerous instances of persons in constant communication with plague patients, and even wearing their clothes, escaping the disease. Odessa has one of the best organised quarantine establishments in the world; yet not long ago the plague broke out in it, entered the town, destroyed a number of inhabitants, and ceased at a particular season. In 1835 the harem of the pasha of Egypt consisted of about 300 persons; but notwithstanding the severest cordon, the plague entered, and seven died within. The cordon was composed of 500 men, who were in constant contact with the town, where the disease was raging violently; of these only three died, so that the proportion of those who perished within to those without was nearly as 4 to 1. The plague of 1665, which ravaged most parts of this kingdom, never visited Oxford, although the terms were kept there, and the court and both houses of parliament were held there; a close correspondence too was maintained between this city and the metropolis, where it was raging. The Persians, although their country is every year surrounded by the plague, seldom suffer anything by it themselves. 'The Turks and Moors,' says Bruce, 'immediately after St. John's day, expose in the market-places the clothes of the many thousands that have died of the plague during its late continuance; and though these consist of furs, cotton, silk, and woollen cloths, which are stuffs the most retentive of the infection, no accident happens to those who wear them.' Clot Bey, who is at the head of the medical department in Egypt, and has treated thousands of cases, says, that removed from malaria or miasm, he has never known the plague to be communicated by contact. He has twice inoculated himself with the pus and blood of those affected with plague, but without producing the disease.

This fully agrees with the evidence that was given before a select committee of the House of Commons, on the contagion of plague in 1819. It appears from the Custom-house Returns, that none of the expurgators of goods in Great Britain, at the quarantine establishments, have ever taken the plague. What then are we to regard as the cause of pestilence, and whence is it to be sought? Undoubtedly in the miasm of pestiferous soils; or of crowded, ill-ventilated, and filthy localities. When plague has at any time become epidemic, these are the spots in which it has first planted itself, and in which it has committed the greatest devastation. Notwithstanding the obviousness of this fact, it is a remarkable circumstance in connection with the history of plague, that no people in the world have been willing to acknowledge their own country to be the first or indigenous seat of pestilence. The doctrine that it is imported and not indigenous, is as prevalent in Turkey as it is in Egypt. The Egyptian Levantines insist that it has never been an Egyptian endemic, but has been imported by travellers or goods; while the Turks contend that it is from Egypt. In the eloquent language of Dr. Hancock, 'Egypt disowns it; Ethiopia has no such progeny; Syria is too genial for its production; and Constantinople harbours it through neglect or sufferance. As to the north, how could the temperate climate of Britain generate a principle so terribly destructive?' Facts however are too numerous and weighty to allow us a moment's hesitation on this point. Wherever civilization has advanced, there plague has receded, till it is now only to be found lurking among the swamps of Egypt or revelling in the filth of Constantinople. It is the spring, we have seen, that is so fatal to the Egyptians, about which time south winds prevail, loaded with putrid emanations from animal and vegetable substances in the lakes formed by the retiring waters of the Nile. In June, the wind is in the north, passing over the Mediterranean, and this is the most healthy and salubrious season. In Constantinople, the month of August is most fatal, and this is the season of the year when decomposition goes on with greatest rapidity. The exemption of the city of Oxford, in the plague of 1665, is a strong proof of the correctness of these opinions. The following words from Quincy are much to the purpose: 'Dr. Plott observes, the reasons why Oxford is now much more healthful than formerly, to be, the enlargement of the city, whereby the inhabitants, who are not proportionately increased, are not so close crowded together; and the care of the magistrates in keeping the streets clear from filth. For "formerly," he says, "they used to kill all manner of cattle within the walls, and suffer their dung and offals to lie in the streets. Moreover about those times, the Isis and Cherwell, through the carelessness of the townsmen, being filled with mud, and the common-shores by such means stopped, did cause the ascent of malignant vapours whenever there happened to be a flood. But since that, by the care and at the charge of Richard Fox, bishop of Winchester, in the year 1517, those rivers were cleansed, and more trenches cut for the water's free passage, the town has continued in a very healthful condition, and in a particular manner so free from pestilential diseases, that the sickness in 1665, which raged in most parts of the kingdom, never visited any person there, although the terms were there kept, and the court and both houses of parliament did there reside."' Now what was done in Oxford, as early as 1517, to remedy its unhealthiness, has since been done in all the principal cities of this country and on the Continent. Accordingly we find that the plague has not visited us since 1665. Holland, which has no system of quarantine, has experienced an exemption corresponding to that of our own country. Paris has not been attacked since 1668, and a century has elapsed since the plague of Marseille.

Treatment of Plague.—The preventive treatment of plague will be gathered from what we have said respecting the causes of this disease, and the most effectual barriers that can be opposed to its future introduction into Europe, are, to adopt again the language of Dr. Hancock, 'the barrier of cleanliness in our towns and villages against filth and crowded habitations; the barrier of Christian charity towards our poor against famine and distress; the barrier of peace against the desolating evils of war; and the barrier of industry against the vice of sloth.' With regard to remedial measures, it appears little can be done towards arresting the progress of plague after it has once declared itself in an individual. Our efforts therefore are limited to removing the patient from those sources of miasm which gave origin to his disease, and in placing him in those conditions which are most favourable for his recovery. Free exposure to fresh air, supporting the strength, and regulating the secretions, are the only means which promise much chance of success. When this plan is adopted, we have the authority of our latest writers on this subject for declaring that the mortality of the disease may be considerably diminished. Thirty per cent. only, of those attacked, die under this mode of treatment; while in the lazaretto at Alexandria, 90 per cent. died in 1833, and 77 in 1836. With respect to the management of buboes and carbuncles, they must be treated in the way which is found efficacious in their removal when uncomplicated with plague, and if by these means we are unable to effect their dispersion, suppuration may be promoted by the employment of emollient cataplasms or any other mild stimulant.

In the following chronological table of some of the principal plagues upon record, we have purposely omitted the mention of many which, although described under that name, are obviously a different disease; even among those we have selected, the vagueness with which the symptoms of some are described, leave us in doubt whether the disease was the same as that which at present goes under the name of plague:—

1799. In the French army in Egypt. Sotira, *Mémoire sur la Peste observée en Egypte pendant le Sejour de l'Armée d'Orient dans cette Contrée;* Baron Larrey, *Description d'Egypte, &c.*

For further accounts of the plague, as it has appeared more recently, see Tully's *Hist. of the Plague in the Islands of Malta, Gozo, Corfu, Cephalonia, &c.*, 1821; also Dr. Bowring's *Observations on the Oriental Plague and on Quarantine, &c.*, 1838.

Pestilential, Epidemic, or Asiatic Cholera is a disease not less fatal than that described in the preceding article; and in its endemic origin, its occasional epidemic eruptions, its selection of victims, and the localities which it ravages, it bears a striking resemblance to plague. Its essential character is however perfectly distinct, as will be seen by the following account of the symptoms of cholera. The disease has two well-marked stages: the cold or choleric, called also the stage of collapse; and the hot or febrile stage, or that in which reaction takes place. The first is generally preceded by certain premonitory symptoms, among the most prominent of which is diarrhœa, accompanied usually with languor and some degree of nausea; the dejections are fæcal and bilious, and often very copious. The commencement of the purging may precede the accession of the febrile stage for several days, or only a few hours may elapse. It is important not to think lightly of this disorder during the prevalence of epidemic cholera, for many a life might have been preserved if timely warning had been taken, and appropriate treatment adopted for removing it, before the accession of the symptoms about to be described.

Symptoms of the Cold Stage.—The time of its invasion is, in the majority of instances, from two to four o'clock in the morning. The patient is attacked with uneasiness of the stomach, to which speedily succeed vomiting and purging of a watery, colourless, and inodorous fluid, similar to barley-water, or more frequently to rice-water: sometimes it is like milk, and occasionally yellowish; but the 'conjee-stools,' as they are termed, which consist of albuminous flakes floating in serum, or discharges of pure serum, are of the most frequent occurrence. These discharges are attended with severe cramps in the extremities, especially in the calves of the legs, and are succeeded by exhaustion, giddiness, and sinking of the pulse; the pulse is small, weak, and accelerated; and after a certain interval, becomes imperceptible. The skin is cold from the commencement; and as the disease advances, it becomes gradually colder, and is covered either with a profuse sweat or a clammy moisture. The features are shrunk and anxious: there is restlessness and agitation, with great thirst, heartburn, and hurried respiration. Notwithstanding the coldness of the body externally, the patient complains of heat, and throws off his bed-clothes. As the cold increases, the skin frequently becomes blue; the eyes, which are dull and suffused, seem drawn into and fixed at the bottom of their sockets; the tongue is cold, but moist; the voice is feeble, hollow, hoarse, and interrupted; but the mental functions remain undisturbed to the last. At this advanced period the collapse is complete, the respiration very slow, and the patient, who suffers little or no pain, presents the appearance of a person who has been dead for some time. The urine is usually suppressed throughout the whole of this stage; but the dejections, becoming thinner and thinner, continue to the last. Some patients, although blue, cold, and pulseless, have sufficient strength to go about· many however die of exhaustion before all these symptoms have declared themselves. In the majority of cases the spasmodic symptoms are first observed, and afterwards the collapse: the former are characterised by pain, evacuations, and moans; the second, by the suppression of voice, urine, and heat. If however the patient get over the cold stage, that of reaction commences. The coldness and blueness gradually disappear; the pulse returns, increasing in force and frequency; to the pale or blue cheek succeeds the flush; the eye brightens; the tongue, which was of a dirty white, becomes cleaner and dry; vomitings are less frequent, but diarrhœa continues; and there is some tenderness of the abdomen, with thirst, great disgust of food, and intense headache. The urine however is secreted; and if all goes on well, at the end of two or three days the features assume their usual expression; the stools are less frequent and more natural; the strength and appetite begin to return; the pulse resumes its ordinary character; and the patient is convalescent. Several varieties occur in the duration and intensity of cholera, and complications are sometimes produced of a character not less fatal than the disease itself. We are informed by M. Dalmas, that soldiers attacked in full march will retire from the ranks, lay down their arms by the road-side, and expire in two hours. During the prevalence of the last epidemic in India, several instances were heard of at Houbley and other places in that country, of natives being struck with the disease while walking in the open air; they fell down, retched a little, complained of vertigo, deafness, and blindness, and expired in a few minutes. This rapidly fatal form of cholera has not been observed in this country. The most severe cases that we have met with generally lasted five or six hours; but the average duration of the fatal cases, when they did not terminate in consecutive fever, was from twelve to fourteen hours. When reaction was established, and fever supervened, the duration of fatal cases was from four to ten days. As a general rule to guide us in forming a prognosis, it may be stated that the more complete is the collapse, the greater is the danger; and if the patient survive it, the more violent and malignant is the subsequent fever. The cases in which spasms and vomiting are most violent are by no means the most dangerous.

Morbid Anatomy of Cholera.—Dissection presents us with nothing satisfactory by which we can judge of the nature of the disease. There is general venous congestion of all the important organs in the body; but it is rare that any traces of inflammation are discovered. The gall-bladder is mostly distended with bile, and its ducts are constricted. In the stomach and intestines is found either a transparent or a turbid serous fluid, mixed with a white opake substance in the form of flakes, and similar in all respects to the matters ejected during life. The mucous membrane lining the intestinal canal is most frequently of a pale white colour, and somewhat more soft and pulpy than in its natural condition; but occasionally some degree of vascularity is observed. The urinary bladder is empty and contracted. With respect to the blood, it is found to be more viscid, and darker coloured than natural, which arises from a deficiency of its saline and watery components, and a relative increase of its solid constituents. In 1000 parts of serum, Dr. O'Shaugnessy found 133 of albumen, whereas healthy serum contains only 78 parts. On comparing the blood with the matter found in the intestines, it is manifest that the latter contains all the ingredients of the blood, except the red globules; and that the aqueous and saline parts pass out of the circulation more rapidly than the albuminous.

History and Statistics of Cholera.—The last outbreak of pestilential cholera, which commenced in India and traversed successively nearly every country in the world, was perhaps the most diffused and best observed of any similar visitation: the observations we shall have to make will therefore chiefly relate to this epidemic. It originated in the district of Nuddeah and in some other parts of the delta of the Ganges, about the end of May or the beginning of June, 1817. During that year it did not extend beyond the territory of Lower Bengal; but in 1818 and the early part of 1819 it diffused itself throughout the extreme length and breadth of the Indian peninsula, yet leaving untouched many districts placed between its lines of movement. Its progress along the lines selected was wonderfully uniform, being, for some successive months, at the rate of about one degree in a month. As early as 1818, it extended itself beyond the boundaries of Hindustan into the Burmese empire and other parts of Eastern Asia, and making gradual progress through these countries, reached China in 1820, and in the following year visited the numerous and populous islands of the Indian Archipelago. The Isle of France suffered its invasion in 1819, and some cases occurred in the same year at one point in Bourbon. In 1821 it extended along the shores of the Persian Gulf, and, during this and the following year, spread through parts of Arabia, Persia, and Syria, and closely threatened Europe. It appeared in the Russian territories in 1823, at Tefflis, Orenburg, and Astrakan; but its farther northern and western progress was stopped for a time. It however re-appeared in Orenburg in 1828, and again in 1829, and in 1830 advanced through the southern provinces of the Russian empire, till it reached Moscow on the 28th of September of that year, and Petersburg the year following. Warsaw was attacked in March, 1831; Danzig in May; Berlin, in August; Hamburg and Sunderland in October; and London and Paris in 1832. At the end of 1833 it had reached Mexico and several other parts of America. We see that the course of the epidemic was principally from east to west, and it was observed that prior to its appearance in many countries, and during its continuance, easterly winds were uncommonly prevalent; but most accurate and extensive meteorological observations, made daily during the continuance of the disease, prove that neither variations of temperature, fluctuations of the barometer, change of wind, nor the prevalence nor absence of moisture, affect in the slightest degree its duration or intensity. Bowel complaints appear to have preceded the cholera in most places, and to have continued for some months after its cessation. In many localities the disease existed only for a few weeks, while in others it lingered for several months. In the first case, the mortality was invariably high; in the last, the malignancy of the disease generally diminished as its stay was prolonged. Into whatever country or town the disease advanced, its first and most deadly fury was expended upon the poorest and most miserable of the population, and upon those who inhabited crowded districts, or low humid localities bordering on a port or river. Among this class of individuals whole families were sometimes cut off by it; indeed it is a peculiar feature of epidemic cholera that its ravages are confined almost exclusively to the poor. When the disease has appeared in a family occupying a station in life above the labouring class, we have the authority of Dr. Brown for declaring that in every case it has been confined to the individual first attacked, and has not in any instance spread to the other members of the family. The mortality from this disease is very great; but it varies somewhat in different countries and at different stages of its epidemic career. During its early prevalence in India, in 1817 and 1818, we learn, from the 'Report to the Medical Board at Bombay,' that there is reason to believe that of 1294 cases which received no medical assistance, every individual perished; and it is added, that it is not ascertained that any person has recovered to whom medicine had not been administered. This appalling statement however is without parallel, and it is gratifying to know that where the premonitory symptoms have been combated by early and judicious treatment, the mortality has always been diminished. This is strikingly exemplified by the statistical records kept at our different military stations in various parts of the world. In all situations and under all modes of treatment, about one in two died of the cases in civil, and one in three of those in the military hospitals; a result doubtless to be attributed to the strict surveillance exercised over the troops, by which nearly one-half of the cases among them were noticed in the premonitory stage, and consequently could be treated with a greater prospect of success than those in the civil hospitals, where the great majority of the patients were far advanced in the disease before they applied for medical aid. Of the severe cases however the mortality is probably nearly the same in all, being about 60 per cent. One of the most extraordinary features of this epidemic, observes Major Tulloch, is that the proportion of deaths to the number attacked has been very nearly alike in all the military commands of which the medical records have been investigated: for instance—In the United Kingdom, the deaths were 1 in 3¼; in Gibraltar, 1 in 3½; in Nova Scotia, 1 in 3⅓; in Canada, 1 in 3; in Honduras, 1 in 3; in the Mauritius, 1 in 8⅓. The Mauritius appears to be the only exception to this; so that either the epidemic was less severe in its character, or the remedies employed were more successful.

The influence of age on the mortality by this disease among the troops of the line serving in Canada is exemplified in the following table:—

Age.	Ratio of Deaths at each Age, per 1000 of strength, by Epidemic Cholera.
Under 18	—
18 to 25	15·5
25 to 33	23·
33 to 40	36·6
40 to 50	70·6

It appears from the authority to which we are indebted for the foregoing table, that females were attacked in very nearly the same proportion as males, but that the cases proved more generally fatal. Children were in a great measure exempt, though, when attacked, they rapidly sunk under it. The greater mortality of the disease in females has also been observed in this country. Dr. Ogden informs us that of 145 fatal cases of cholera at Sunderland, 63 were males and 82 females. The information which we possess on the relative mortality of the disease in the different races of mankind is rather meagre. The native Indians of North America suffered from it in an equal degree with the white population; and the same was observed with regard to the Sepoys in our Indian army. In the Mauritius, whose population in 1831 was 90,000, of which 25,000 were whites and the rest coloured, the total number of deaths recorded in the civil and military hospitals was 1327. Of these 168 were whites, 162 coloured, and 997 blacks, principally negroes, who seemed peculiarly subject to the disease. This great susceptibility of negroes to the invasion of disease, when absent from their native land, we have had occasion to notice in the article Phthisis; and that time seems to have had little effect in weakening this susceptibility, appears from a comparison of the mortality among them in the present epidemic with that which took place during a similar epidemic in this island in the year 1775. At this date, more than 2000 out of 4300 slaves belonging to government were cut off by it, and of those belonging to the planters nearly as many.

Causes of Cholera.—That the whole series of phenomena results from the action of a morbific poison on the body, there can be no doubt; that this morbific matter is indigenous to some countries, and apparently has its origin in certain peculiar conditions of the soil, is supposed to be true from the effects which we find to be produced upon animal bodies living in these districts. But why the miasm arising from the overflow of the Nile should produce plague; that of the Ganges, cholera; that of the parts situated in the tropics, yellow fever; or our own marshes, simple intermittent—we are entirely ignorant; nor can we, in the present state of our knowledge, at all account for the epidemic spread of some of these endemic diseases. The doctrine of contagion has been had recourse to in cholera, as in many other diseases, in order to explain its diffusion, and it has been asserted by the advocates of the exclusive operation of this principle, that the disease has always been found to move in the line of human intercourse; and it must be acknowledged, observes Dr. Brown, that while so migratory an animal as man inhabits the earth, it cannot well do otherwise. But if it is meant to be asserted that its diffusion has been in proportion to the intercourse between infected and healthy districts, the assertion is by no means supported by facts. Its appearance at Madras, for instance, whither, according to this doctrine, it ought to have been conveyed almost three months earlier by trading vessels from the infected districts, was simultaneous with its appearance in parallel latitudes in the interior. It did not reach Ceylon, to which, on the contagious principle, it ought to have been conveyed much earlier by shipping from the infected points of the coast, until it had previously gained the nearest point to it on the continent, and had been long prevalent on both coasts of the peninsula. In its importation into this country likewise, supposing it to be imported, so far from following the great routes of human intercourse, it chose one of the least frequented paths. The principal evidence on this point, which was collected during the last epidemic cholera, goes to negative its contagious character; and the advocates of the contrary opinion are at present by far the more numerous party. Of fifteen medical reporters in India who had observed the disease, two only thought it contagious, eight were of a contrary opinion, and five were doubtful. The medical officers at Gibraltar seem to have been almost unanimous in their opinion that the disease was not contagious. In the same ward with the cholera patients in the civil hospital were several persons labouring under other diseases, who, although in constant communication with and frequently in attendance on those suffering under the epidemic, were in no instance affected by it. In the military hospital too it was observed that the orderlies employed in attendance on the sick were not attacked in a greater proportion than others who were not so employed; and of thirty medical officers in constant attendance on the sick during the prevalence of the epidemic, all of whom, from the nature of their duties, were subject to great fatigue and anxiety, only one or two exhibited any symptoms of the disease, and their cases were comparatively slight. Nevertheless it is probable that under some circumstances cholera may be contagious, and this opinion derives support from the great mortality which was always observed under the operation of the quarantine laws, on the inutility of which, in this disease at least, all medical men are agreed. The predisposing causes of cholera may be gathered from its history. The poor, the old, the infirm, and the dissipated were the principal sufferers. In the north of Germany, Tuesday was always the day of the greatest mortality, owing, it was supposed, to the excesses committed on the two or three preceding days. Hence every circumstance which tends to debilitate the system generally, whether occasioned by atmospheric vicissitudes, by residence in an unhealthy locality, by unwholesome or insufficient food, by the abuse of spirituous liquors, or by debauchery, acts as a predisposing cause in the production of cholera.

Treatment of Cholera.—Premising, in a prophylactic point of view, the superiority of avoiding all the predisposing causes of cholera to the absurd practice of swallowing specifics against the disease, our treatment must be regulated according to the state in which we find the patient. If the premonitory symptoms only are present, the stomach should be unloaded by an emetic, and a table-spoonful of good mustard constitutes a very efficient one. The diarrhœa may be treated by a full dose of calomel and opium, combined with some aromatic, and a blister should be applied to the abdomen. Bleeding also has been recommended at this period of the disorder. If the patient is already in a state of collapse, the various modes of treatment which have been adopted prove how little is to be effected when the disease has advanced to this stage. Major Tulloch informs us that the principal remedy of the American aborigines consisted in merely swallowing large quantities of charcoal mixed with lard; yet very nearly the same proportion recovered as among the white inhabitants of the towns who had the advantage of the best medical science. In this country, blood-letting, cold affusion, hot-baths, emetics, purges, astringents, sedatives, and stimulants of the most powerful kind, have been successively tried with very doubtful advantage. The plan however which has excited most attention is that by salines. Medical men, guided by chemical analysis, conceived the project of supplying by artificial means the serum which was found wanting in the blood. With this view lavements and potions of an alkaline solution, resembling serum in composition, were administered; but not being able by this means to arrest the vomiting, it was recommended and put into practice by Dr. Latta of Leith to inject the same fluid into the veins. This was first done by means of one of Reid's syringes, the temperature of the solution being kept at from 108° to 110° Fahr. Of 74 bad cases treated in this method, 22 recovered, and in one case only did any unfavourable symptoms occur, and this was from phlebitis, or inflammation of the veins. As much as 33 lbs. of this alkaline solution have been injected in the space of 52 hours, and with a successful result. Some practitioners have even exceeded in amount this quantity. The composition of the saline injection employed by Dr. Latta consisted of two drachms of common salt and two scruples of carbonate of soda dissolved in sixty ounces of water; but this formula has been slightly varied in different cases. The immediate effects observed on injecting this fluid into the veins are, an increase of the temperature and perspiration, a reappearance of the pulse, if before imperceptible, or it becomes fuller, stronger, and slower, when it was before small, frequent, and feeble. The collapsed appearance of the countenance gradually vanishes; it becomes fuller and more natural; the eyes brighten, the thirst diminishes, and the patient expresses himself in terms of gratitude or satisfaction at the wonderful change wrought in his feelings. But this change is evanescent; the purging continues, and the patient is shortly reduced to the same hopeless state in which he was previous to the adoption of this treatment. By recommencing the injections, the same beneficial results are obtained, and, provided this treatment prove successful, the patient does not again relapse into his former condition, but the diarrhœa and vomiting diminish, and reaction commences. With respect to the treatment of the febrile stage of cholera little need be said. The same recognised principles that are applicable to the treatment of pyrexia in general must be our guides in treating this fever; and the physician should never neglect to impress upon his patient the probability of a relapse, if he should indulge too soon in any dietetic or other irregularities.

PETAL is one of the inner divisions of the organs clothing a flower, and called floral envelopes. These are usually double, the outer being a calyx composed of sepals, and the inner a corolla composed of petals. Both these parts are leaves incompletely organised. The petal, being fugitive, and of very temporary utility, is generally the more delicate, containing no woody tissue to protect the spiral vessels. It is sometimes of extraordinary size, but is as frequently a very minute body. [Corolla; Morphology; Flower.]

PETALISM. [Ostracism.]

PETALITE, a mineral which occurs massive. Structure perfectly lamellar in one direction. Cleavage parallel to the lateral planes, and both diagonals of a rhombic prism. Fracture uneven. Hardness 6·5. Brittle. Colour greyish, greenish, or reddish-white. Streak white. Lustre vitreous, inclining to resinous. Translucent. Specific gravity 2·42 to 2·45. When heated in acids, it undergoes partial decomposition; emits a blue phosphorescent light when gently heated. When by itself, it melts with difficulty, and only on the edges; but with borax, it fuses into a colourless glass.

It occurs at Utön in Sweden, and in North America. It consists, according to Gmelin, of—Silica, 74·17; Alumina, 17·41; Lithia, 5·16; Lime, 0·32; Water, 2·17.

PETARD. [Artillery.]

PETAURUS. [Marsupialia, vol. xiv., pp. 460, 461.]

PETA'VIUS, DIONYSIUS PETAU, born at Orleans, in 1583, studied at Paris, and afterwards entered the order of the Jesuits. He lectured on rhetoric in the colleges of Rheims, La Flèche, and lastly at Paris, in which he was made professor of theology in 1621. He applied himself assiduously to classical and historical studies, and became a distinguished scholar and critic. In 1627 he published his great work on chronology, 'De Doctrinâ Temporum,' 2 vols. folio, which was republished with considerable additions by himself, as well as by Hardouin and others, in 3 vols. folio, Antwerp, 1703. The 'Doctrinâ Temporum' consists of 13 books. In the first 8 books, Petau discusses the principles of the science of chronology, antient and modern; in books 9 to 12, he examines the application of chronology to history, the various æras, &c.; and in the last or 13th book he gives chronological tables of the principal events from the creation to the reign of Justinian. After the publication of the work, Philip IV. invited Petau to Madrid to fill the chair of history, but Petau declined the offer, as well as an invitation to go to Rome by Pope Urban VIII., preferring the tranquillity of his cell in the Jesuits' college of Clermont at Paris, where he died in 1652. Just before his death he published 'Rationarium Temporum,' 2 vols. 8vo., 1652, which is a kind of abridgement of his great work, and forms a useful manual of universal chronology. It has gone through many editions, and has been translated into French: 'Abrégé Chronologique de l'Histoire universelle, sacrée et profane,' 5 vols. 12mo., Paris, 1715. Perizonius published an edition of the 'Rationarium Temporum,' with a continuation down to 1715. At the end of the work are lists of the Roman consuls, the popes, the emperors of the Eastern and Western empires, of the various dynasties of modern Europe, as well as of the councils, and of the various heresies and schisms. Petau wrote also 'De Theologicis Dogmatibus,' 3 vols. fol., Antwerp, 1700. He edited the Breviarium of Nicephorus, in Greek and Latin, with notes, Paris, 1648; the works of Synesius, bishop of Ptolemaïs in Cyrenaica; and those of St. Epiphanius, with a Latin translation, 2 vols. folio, Paris, 1622. He also wrote a dissertation upon Photinus, 'De Photino Heretico.'

PETE'CHIÆ are small spots of a dark red colour produced by the effusion of drops of blood in the skin just beneath the cuticle. At first sight they look very like flea-bites, but they do not disappear when they are pressed with the finger. They usually indicate an altered state of the blood, and are often symptoms of very serious diseases, as in typhus fever (some varieties of which have hence been called petechial fever), scurvy, purpura, &c. They commonly appear also in very severe cases of small-pox, measles, and scarlet fever, and are amongst the worst symptoms by which those diseases are marked.

PETER, ST., one of the twelve Apostles, was born at Bethsaida, on the western side of the lake of Gennesareth. His name at first was Simon, which was changed by our Lord into Cephas, a Syriac word signifying a stone or rock; in Greek, *petra*, whence Peter. In conjunction with Andrew his brother, he followed the occupation of a fisherman. Both were hearers of John the Baptist, by whom they were taught that Jesus Christ was the Messiah. While plying their business on the sea of Galilee, the Saviour called them to be his disciples:—'Follow me, and I will make you fishers of men:' immediately they quitted their boats and nets, and became his intimate friends and constant associates. Peter was one of the three, James and John being the others, who were favoured by our Lord with peculiar marks of his confidence.

Peter was a man of an open and generous nature, strong in his attachments, ardent, and precipitate. He was prompt on every occasion to exhibit his zeal in behalf of his master, of which we have a memorable instance in his conduct towards the high-priest's servant, whose ear he cut off when the Jewish officers were about to apprehend our Lord. Yet, notwithstanding the ardour of his character and his solemn declaration to the contrary, he denied Christ when he was in circumstances of danger. After the denial, 'Jesus turned and looked upon Peter.' That look entered his heart; and stung with deep compunction, he went out and wept bitterly.

On the day of Pentecost which succeeded the ascension of our Lord, the Holy Ghost descended upon the Apostles, and produced the most astonishing and extraordinary results. The gift of tongues came upon them; and they were enabled to address the inhabitants of different nations, each in his own language. On this occasion the character of St. Peter sustained a singular change; and he preached with so much effect, that three thousand were converted to the Christian faith. He now took a prominent position among the Apostles. When a miracle is performed, it is Peter who avails himself of the opportunity, and preaches to the people. When brought before the council for declaring the resurrection of their Master, it is Peter who speaks in reply to the charges against them. In the case of Ananias and Sapphira, it is Peter who detects and punishes the fraud.

Being at Joppa in the course of his apostolic labours, he converted Cornelius, a Roman centurion, the first Gentile who was admitted into the Church without circumcision. This event was considered satisfactory evidence that the benefits of the Gospel were intended, not for the Jews only, but for mankind universally. Shortly after, the zeal and success with which he propagated the new religion induced Herod Agrippa to cast him into prison, from which he was miraculously delivered by an angel. The last important transaction in which we find him engaged was in the apostolic council held at Jerusalem, A.D. 49, when it was decided that Christianity required of its converts neither circumcision nor the observance of any other rite of the Jewish institute. It is supposed that he afterwards preached to the Hebrew Christians dispersed through Pontus, Galatia, Cappadocia, Asia Minor, and Bithynia; and that he visited Rome, A.D. 63, where he soon after suffered martyrdom.

St. Peter was the author of two Epistles, both of which make part of our canonical Scriptures. The first, whose genuineness and authenticity have never been questioned, is addressed 'to the strangers scattered throughout Pontus, Galatia, Cappadocia, Asia, and Bithynia.' There is much difference of opinion among the learned with respect to the persons here denominated *strangers*. Some suppose they were Jewish Christians; others, that they were in the first instance proselytes to Judaism, and then converts to Christianity; others again, that they were Christians in general. There are two considerations which induce us to hold that the first is the more probable opinion. The word *strangers* (Παρεπίδημοι) properly signifies persons from another country; and therefore it is very suitably applied to those Jewish believers who, in consequence of persecution in Judæa, were obliged to take refuge in distant provinces: and again, since the ministry of the circumcision was committed to St. Peter, it is more likely that he should address himself to his own converts than to Gentiles.

Another controversy has been agitated with respect to the place where the Epistle was written. In the concluding verses, it is implied that the Apostle was then at Babylon; but whether the word is used in a real sense to designate the city of that name, or mystically to signify Jerusalem or Rome, is the matter in debate. In all probability the term is employed for Rome; for the Jews were fond of using figurative appellations, especially in their national distresses. Edom was frequently a name for their heathen oppressors; and as Babylon was the cause of their first dispersion and captivity, it is not unlikely that Rome, the instrument of their second, and which so closely resembled Babylon in her 'abominations, idolatries, and persecutions of the saints,' should be denominated by the same title.

As St. Peter arrived in Rome, A.D. 63, and suffered martyrdom about 65, the Epistle may be dated in 64. It was written in a period of general calamity to the Church; and the design of the Apostle is to console and strengthen his converts in their trials, and teach them how to bear persecution. He exhorts them to honour and obey the civil authorities; and, above all things, to lead a holy and blameless life, that they might stop the mouths of their enemies and calumniators, and by their example gain over others to the side of Christianity.

The best critics speak highly of the excellence of this Epistle. One says it is sparing of words, but full of sense; another calls it majestic; and a third declares it one of the finest books in the New Testament, composed in a strain which demonstrates its divine authority. The writer displays a profound knowledge of the Gospel, and a deep conviction of the truth and certainty of its doctrines. Careless about the disposition of his words and the rounding of his periods, his heart is absorbed and his thoughts swell with the importance and grandeur of his subject. His style is vehement and fervid, and he speaks with the authority of the first man in the Apostolic college.

His second Epistle was written soon after the first. Its object is to confirm the instructions which he had formerly delivered, to establish his converts in the religion that they had embraced, to caution them against false teachers, to warn them against profane scoffers, and to prepare them for the future judgment of the world.

(Horne's *Introduction*; Macknight; Benson; Michaelis.)

PETER, ST., MARTYR. [Office, Holy.]

PETER OF BLOIS, better known by his Latinised name Petrus Blesensis (Blois being his birth-place), a writer of the twelfth century, who spent much of his life in England, being invited thither by King Henry II., who gave him the archdeaconry of Bath. There is a large volume of the writings of this Peter, consisting very much of letters, from which a far better account of his life might be collected than any which has yet been prepared. He was in great favour with Richard, who succeeded Becket in the archbishopric of Canterbury, and was his chancellor. He had also in England the archdeaconry of London, having resigned his archdeaconry of Bath. Peter was a scholar of John of Salisbury; and before he came to England he had studied at Paris and Bologna, and had been secretary to William II., king of Sicily. He died in England in 1200. The edition of his works by Pierre de Goussainville, folio, 1667, is accounted the best. His works belong to the series known as the Fathers of the Church.

Peter visited Bologna for the purpose of acquiring a knowledge of Roman law, and his letters contain numerous indications of his acquaintance with this subject. A work of his on canon law and process has lately been discovered, of which an account is given in the *Zeitschrift für Geschichtliche Rechtswissenschaft*, vol. vii., p. 207. (Savigny, *Geschichte des Römischen Rechts im Mittelalter*.)

PETER OF SICILY. [Sicilies, the Two, Kingdom of.]

PETER THE CRUEL, DON PEDRO I., son of Alonso XI., after his father's death succeeded to the united crown of Castile and Leon, A.D. 1350, being then only sixteen years of age. His first step was to put to death Leonora de Guzman, the mistress of his father, who had several children by her. His next proceeding was to command the city of Burgos to pay a certain tax without the sanction of the Cortes, but the people resisted and killed the collector. Upon this Pedro went to Burgos, accompanied by Don Juan de Albuquerque, his unprincipled councillor, and having summoned Garcilasso de la Vega, the adelantado of Castile, into his presence, ordered him to be instantly put to death by his ballasteros, or men-at-arms. In 1352, he assembled the Cortes at Valladolid, and endeavoured, but without success, to obtain the abolition of the Behetrias, which was the name given to the political condition of certain towns that had placed themselves under the protection of some powerful noble, and were in great measure independent of the crown. He next proceeded to Ciudad Rodrigo, where he had a conference with his maternal uncle, Alonso or Affonso IV., king of Portugal, who gave him the best advice as to the necessity of moderation, and above all as to adopting conciliatory measures towards his half-brothers, the sons of Donna Leonora, who possessed great influence in the country. Pedro listened to the advice, and he even invited the eldest of his natural brothers, Don Enrique, called Enrique of Transtamare, to his court, where another brother, Don Tello, already was. But his brothers did not trust him, and they soon left Pedro, rebelled, were defeated, and emigrated into Aragon. In 1253, by the advice of his ministers, Pedro solicited and obtained the hand of Blanche of Bourbon, a princess of the royal house of France. Pedro, who had a mistress, Maria de Padilla, behaved with coldness to his bride, and soon confined her in the fortress of Arevalo. He next conceived a passion for Donna Juana de Castro, a young lady of a noble family, and in order to marry her, he pretended, upon some grounds unknown to us, that his marriage with Blanche was null, and he found some prelates, the bishops of Salamanca and Avila, who took his part. In 1354, he publicly married Juana at Salamanca, but he soon abandoned her also, on the ground that he had deceived her as well as the prelates. Not long after Juana was brought to bed of a son. Her brother, Fernando Perez de Castro, a powerful lord of Galicia, incensed at his sister's treatment, raised the standard of revolt, and joined the king's brothers and other discontented nobles. Queen Blanche being rescued from her guards, the citizens of Toledo declared themselves her champions and defenders. The league thus formed became too powerful for Pedro, and on the interference of the pope's legate, the king promised to discard Maria de Padilla and to live with Blanche. On this condition the papal legate abstained from excommunicating him, but Pedro shortly after, having obtained supplies from the Cortes at Burgos, resumed the war, confined Blanche to the fortress of Siguenza, surprised the towns of Toledo and Toro, and put to death many of the leaders of the league; the rest escaped into Aragon. In 1358, Pedro having got into his possession his natural brother Fadrique, grand-master of the order of St. Iago, ordered him to be put to death by his guards in his own presence. Fadrique's brothers Enrique and Tello kept up a desultory warfare against Pedro on the borders of Aragon and Castile.

Pedro now entered into an agreement with his cousin and namesake, King Pedro of Portugal, for the mutual surrender of their respective subjects. Pedro of Portugal was nearly as cruel, though not quite so unprincipled as his cousin of Castile, and he was then busy in discovering and putting to death all those who had been any way concerned in the murder of his mistress Inez de Castro. [Alonso IV. of Portugal.] In 1360 the exchange of blood was made. The Castilian gave up the Portuguese emigrants, who were put to death, and he obtained the persons of several of his revolted subjects who had fled to Portugal, and whom he speedily despatched, except the archbishop of Toledo, the protector of Blanche, who was only banished. In 1361 that unhappy lady was put to death, it is said by poison, at Xeres, by order of her husband. Soon after, Maria de Padilla died a natural death, and Pedro, having assembled the Cortes at Seville, declared that she had been his lawful wife, and produced witnesses who swore to the nuptials as having taken place before his marriage with Blanche. The Cortes acknowledged the issue of Maria de Padilla to be legitimate.

It was about this time that Pedro committed another atrocious murder, on the person of Abu Saïd, the Moorish king of Granada, who had come to him at Seville with a safe conduct, [illegible] the purpose of doing homage for his kingdom as a fief of Castile. The Moor came with numerous attendants and servants in splendid attire, and brought much valuable property with him. He was invited by

Pedro to an entertainment, in the midst of which a number of armed men entered the hall, seized the Moors, rifled their persons, and dragged them to prison. The following day Abu Saïd, mounted on an ass, and thirty-seven of his companions, were paraded through the streets of Seville, preceded by a herald, who cried, that they were condemned to death by King Don Pedro for dethroning their lawful sovereign Mohammed Ben Yúsef. Being conducted to a field behind the Alcazar, Abu Saïd was stabbed to the heart by Pedro himself, whilst his companions were despatched by the Castilian guards, A.D. 1362. Abu Saïd was a usurper, but Pedro was not his judge. He had come to Seville on the faith of a king's promise, and on a friendly errand, and his murder was as unprovoked as it was cowardly. [MOORS, p. 389.]

The king of Aragon, joined by the king of Navarre, as well as by Bertrand Duguesclin and other French leaders and soldiers who resented the cruel treatment of Blanche, invaded Castile in 1366, entered Calahorra, and proclaimed Enrique, Pedro's natural brother, as king. Pedro, who was at Burgos, fled to Seville without fighting. Enrique was acknowledged throughout all Castile, and the people of Seville soon after revolted against Pedro, who fled into Portugal. From Portugal he went into Galicia, where he had some partisans, who urged him to try the fortune of arms; but Pedro, having already, in 1363, formed an alliance with Edward III. of England, depended chiefly upon the assistance of the Black Prince, who was then in Gascony. While passing through St. Iago he committed another deed of atrocity, the motive of which is not clearly ascertained. The archbishop of St. Iago, called Don Suero, was lord of several towns and fortresses, and he was one of those who had urged Pedro to make a stand against his enemies. All at once Pedro sent for him, and on the archbishop reaching the gate of his own cathedral, where the king stood as if to receive him, he and the dean were suddenly pierced by the spears of the guards, and the church was plundered. The strongholds of the archbishop were then occupied by the king's troops, after which Pedro embarked at Coruña, and sailed for Bayonne, A.D. 1366.

Edward the Black Prince engaged to restore Pedro to his throne. Pedro on his part promised him the lordship of Biscay, with a supply of money for himself and his army. Besides the alliance existing between his father and Pedro, the French king, Charles V., being the ally of Enrique, the English prince found it his interest to put his weight in the other side of the scale. In the spring of 1367 the Black Prince, together with Pedro, put themselves in motion with an army of English, Normans, and Gascons, and passing through the defile of Roncesvalles, they crossed Navarre, with the consent of that king, and entered Castile. The Black Prince was joined on his march by Sir Hugh de Calverley and Sir Robert Knowles, at the head of several thousand men, who had served as volunteers in the army of Enrique, but would not bear arms against their own countrymen. The army thus reinforced amounted to about 30,000 men. The army of Enrique was much superior in numbers, but the men were not all true to his cause. The two armies met at Najera, a few miles from the right bank of the Ebro, on the 3rd of April. The battle began with the war cry of 'Guienne and St. George' on one side, and Castile and St. Iago' on the other. Enrique fought bravely, but his brother Don Tello fled from the field at the head of the cavalry, and the Castilian infantry, being charged by the Black Prince in person, gave way. Enrique escaped with very few followers, and retired into Aragon. Pedro, whose ferocity had not been tamed by adversity, wished to kill the prisoners, but was prevented by the Black Prince as long as he remained in Castile. Pedro proceeded to Burgos, and all Castile acknowledged him again. But he behaved faithlessly to his ally; he only paid part of the money which he had promised for the troops, and as for the lordship of Biscay, Pedro excused himself by saying that he could not give it without the consent of the states of that province. The Black Prince, disgusted, and out of health, with his troops half starved, returned to Guienne, where he arrived in July. After his departure Pedro gave vent to his cruelty, and put to death many persons at Toledo, Cordova, and Seville. This gave rise to a second insurrection, and Enrique having again made his appearance, many of the towns of Castile declared for him. Some towns however, and Toledo among the rest, held out for Don Pedro, and a desultory but destructive warfare, as all Spanish wars have been, was carried on for two years. The circumstance of Pedro having still a strong party in many towns, notwithstanding all his cruelty, gives weight to the supposition that while Pedro ruled the nobles with an iron sceptre, he was not so obnoxious to the mass of the people, who were out of the reach of his capricious ferocity. Indeed it is said by Roderic Santius, that he was the scourge of the proud and turbulent, that he cleared the roads of robbers, and that he could be pleasing and affable when he liked.

In March, 1369, Enrique, being joined by Duguesclin with 600 lances from France, laid siege to the town of Montiél, where his brother then was. Pedro, through one of his knights, made great offers to Duguesclin if he would assist him to escape. Duguesclin informed Enrique of these offers, and it was agreed that he should entice Pedro to his tent. On the evening of the 23rd of March, Pedro came to Duguesclin's tent, when Enrique, who lay in wait, fell upon him with his dagger. They grappled together and fell to the ground, but Enrique soon despatched his brother. A Catalonian, quoted by Zurita, says that Enrique's attendants assisted him in overpowering Pedro. Bad as the latter was, there is no excuse for the treachery and foul manner in which he was killed. Enrique II. was then proclaimed throughout Castile.

(Dunham, *History of Spain and Portugal*, and authorities therein quoted; Froissart, *Chronique.*)

PETER THE FIRST, called the '**GREAT**,' Czar of Russia, was born at Moscow, on the 11th of June, 1672. His father, Alexis Michaelovitz, was twice married: by his first wife he had two sons and four daughters; and one son (the subject of this notice) and one daughter (Natalia Alexowna) by his second wife. The Czar Alexis was a man of a liberal mind; he commenced the work of improvement among his barbarous subjects, established manufactures, reduced the laws into a code, resisted the usurpations of the clergy, and invited foreign officers to discipline his armies. He died in 1677, and was succeeded by his eldest son Theodore, a youth of delicate constitution, who died in 1682, leaving no issue. The next brother, Ivan, was subject to epileptic fits, and of so weak intellect that Theodore named Peter as his successor. The princess Sophia, an ambitious woman, who had intended to reign herself, through the medium of her incompetent brother, being enraged at this appointment, engaged the strelitzes on her side, and fomented an insurrection, which was only appeased by Ivan being proclaimed joint sovereign with Peter, and Sophia as regent. Peter narrowly escaped with his life on this occasion, for, having fled with his mother to the Troitski convent near Moscow, at the commencement of the insurrection, he was pursued by some of the strelitzes, who found him before the altar, and were only deterred from striking a fatal blow by feelings of reverence or superstition. When Peter was seventeen, his party brought about a marriage between him and the daughter of the boyar Feodor Abrahamavitz, during the absence of Prince Galitzin, who had been associated by the Princess Sophia with her in the government. On the pregnancy of the Czarina being declared, Galitzin, whose plans were entirely deranged by this event, raised an insurrection, which however was soon suppressed, and Galitzin was banished to Archangel, and forfeited his estates. The Princess Sophia was confined to a convent for the rest of her life, which terminated in 1704.

From this time (1689) Peter reigned supreme; his brother Ivan never interfered, and died in 1696. Peter was now in the eighteenth year of his age. He was tall, stout, and well made; his features were regular, but indicated, when grave, a great degree of severity; at other times he was lively and sociable, and always full of energy and activity. His education had been much neglected, and it is said that the Princess Sophia had encouraged every species of excess by placing about him corrupt companions. Although there is no doubt that much of his time was passed in debauchery, yet it is a strong proof that a portion of it must have been devoted to better objects, that he immediately commenced the vast undertaking of reforming the whole system of government and the manners of the people, in which he had to encounter the jealousies of every class of his subjects, who looked upon these changes as subversive of their antient constitution. Peter's indomitable energy however overcame all obstacles. He first directed his attention to the army, in which department his plans were ably seconded by Generals Le Fort and Patrick Gordon, who, with other foreigners, had entered into his service. He himself entered the army as a private soldier, and rose through all the intermediate ranks before he obtained a commission. He caused all the young boyars to follow this example. He made the soldiers lay aside their long coats, shave their beards, and dress their hair, and in a very short time he had a corps of 5000 men disciplined and trained on the German plan. The sight of a small vessel built by some Dutchmen in his father's time, on the river which runs through Moscow, made a great impression on him, and he determined to have a navy. He hired Dutch and Venetian shipwrights, who built some small vessels at Pskov, in which he used to cruise on the Lake Peipus, until that becoming too confined a space for him, he went to Archangel, where he passed two summers cruising on board English and Dutch ships, and learning the duties of a practical seaman. His taste for everything connected with ships and navigation soon amounted to a passion. He resolved to be no longer dependent on foreigners for his ships, and accordingly sent a number of young Russians to Venice, Leghorn, and Holland, to learn the art of ship-building. By these measures his expenditure had been so much increased that it was necessary to take some steps towards augmenting the revenue, which he did, through the advice of his foreign councillors, by raising the custom-house duties from 5 to 10 per cent., which caused an increase of nearly 2,000,000 rubles in the first year. In 1696, he besieged and took Azoff. During the rejoicings which followed this first victory by the army and navy of his own creation, some of the discontented boyars and strelitzes conspired to put him to death, but, being betrayed by certain of the confederates, the plot was defeated by their arrest and execution.

Russia was not at this period represented at any of the courts of Europe, but Peter, being more than ever convinced of the pre-eminence of the inhabitants of Western Europe over his own barbarous subjects, resolved to visit these countries himself, and for this purpose he despatched an extraordinary embassy to Holland, accompanying it himself incognito. Before he set out on his travels in 1697, he took the precaution of leaving General Gordon, with 4000 of his guards, in Moscow, with orders to remain in that capital. He only took with him twelve attendants, among whom were his favourites, Menzikoff and Galitzin, and his dwarf, a necessary appendage to all great men in Russia. He went straight to Saardam in Holland, took a small lodging with two rooms and a garret, and a shed adjoining. He purchased carpenters' tools and the dress of the dockyard artificers, and there he and his companions spent almost all their time in working as common shipwrights. Peter went by the name of Pieter Timmerman; he rose early, boiled his own pot, and received wages for his labour. He was described by a native of Holland as being 'very tall and robust, quick, and nimble of foot, rapid in all his actions, his face plump and round, fierce in his look, having brown eyebrows and curling brown hair, and swinging his arms in walking.' He spent much time in sailing on the Zuyder Zee, and with his own hands made a bowsprit for his yacht; he also assisted at rope-making, sail-making, and smiths' work. A bar of iron which he forged at Olonetz some years later, with his own mark stamped upon it, is preserved in the Academy of Sciences at St. Petersburg. In the same spirit of inquiry and eagerness to learn, he visited every manufactory, examining into all the details of each. He attended the hospitals, where he learned to bleed and draw teeth; he was very fond of practising in a surgical way. From Holland he proceeded to England, when he arrived in January, 1698. As his chief object in coming to this country was to learn the theory of shipbuilding, and the method of making drafts, and laying them off in the mould-lofts, he did not disguise his annoyance at the crowds which assembled to see him, and at the festivities given in his honour.

The Marquis of Carmarthen was appointed by King William to attend upon the Czar, and they are reported to have passed their nights together in drinking pepper and brandy. Peter visited the dockyards of Deptford, Woolwich, and Chatham. He spent much of his time at Rotherhithe, where a ship was building for him. After his day's work, he and his companions were in the habit of retiring to a public-house near Tower-hill, to smoke and drink beer and brandy. The house still bears the sign of the Czar of Russia. He went to Portsmouth, to witness a grand naval review and sham fight. In April he quitted England, taking with him several men of science, engineers, and officers for his army and navy. He spent a short time in Holland, and then proceeded to Vienna to make himself acquainted with the dress, discipline, and tactics of the emperor's army, then considered the best in Europe. From thence he was preparing to visit Italy, when he received news of a rebellion having broken out among the strelitzes, fomented, it was said, by the priests and the Princess Sophia. His prudence in leaving General Gordon in Moscow was now made manifest. That officer entirely defeated the rebels, many of whom lost their lives and others were thrown into prison to await the return of the Czar. Peter quitted Vienna immediately on the receipt of this intelligence, and arrived at Moscow, after an absence of seventeen months.

The dark side of Peter's character now showed itself in the savage nature of the punishments inflicted on the rebels; in palliation of which it can only be said that this being the third insurrection during his reign, a severe example was required to deter other malcontents. He next ordained that all persons, civil as well as military, should cut off the skirts of their Tartar coats, and shave their beards: a tax was levied on all who disobeyed, which, from the love of the Russians for these appendages, became a fruitful source of revenue. He regulated the printing-press, and caused translations to be published of works on various arts and other subjects, established schools for the marine and the teaching of languages, obliged his subjects to trade with other countries, which formerly subjected them to the penalty of death, and he altered the calendar, much to the horror of the priests, ordering that the year 1700 should commence on the 1st of January, instead of the 1st of September, which day used to commence the Russian year. He also instituted the order of St. Andrew, the patron saint of Russia.

In the year 1700 Peter entered into an offensive league with Poland and Denmark against Sweden. His army was defeated before Narva by Charles XII., on the 19th of November in that year; but far from being dispirited at this event, he was only excited to renewed exertion, and he observed that the Swedes would at length teach his soldiers to beat them. In 1703 he laid the foundation of St. Petersburg; and in the previous year the Russian army, under Scherematoff, had gained a complete victory over an inferior force of Swedes, and immediately after took the town of Marienburg. The war continued with more or less success until the year 1709, when Charles XII., having rashly marched into the Ukraine, was completely defeated by the Russian army under Peter at Pultowa, on the 15th of June. Charles himself escaped to Bender, but his army was totally annihilated.

We have seen that Peter, in his seventeenth year, had a wife forced upon him, who bore him one son, Alexis. The czarina having encouraged the factious party, who opposed all innovation, Peter found it necessary to divorce and confine her to a convent before he had been married three years (1696). His son Alexis was unfortunately left in her guardianship. When the prisoners taken at Marienburg filed off before General Bauer, he was much struck with the appearance of a very young girl, who appeared to be in the greatest distress. She had been married only the day before to a Livonian sergeant in the Swedish service, whose loss she was then mourning. The general took compassion on her, and received her into his house. Some time after, Menzikoff being struck by her beauty, she was transferred to him, and remained his mistress till the year 1704, when, in the seventeenth year of her age, she became the mistress of Peter, and gained his affections so entirely that he married her, first privately and afterwards publicly. On the 17th of March, 1711, he declared the czarina Catherine Alexina his lawful wife. She accompanied her husband immediately afterwards to the war in Turkey, which had just broken out. Peter, following the rash example of Charles XII., entered the enemy's country before his whole army was concentrated. Without sufficient force to keep up his line of communication with Russia, he crossed the river Pruth near Jassy, marched some way down the right bank, and was hemmed in by the army of the grand-vizier on one side, and the Tartars of the Crimea on the opposite shore of the river. After three days' action, the situation of the army became desperate, when Catherine, unknown to her husband, sent a letter to the grand-vizier, with a present of all the plate and jewels she could collect in the camp. After some delay a treaty of peace was signed, by which Peter gave up the towns of Azof and Taganrog, and the vizier supplied the Russian army with provisions. Peter's health was so much impaired after this campaign, that he went to Carlsbad to drink the waters. From Carlsbad he proceeded to Dresden, where his son the czarovitz Alexis Petrovitz was married to the princess of Wolfenbuttel. From Dresden he went to St. Petersburg, where he solemnised anew his marriage with Catherine with great pomp. Peter now determined to strip Sweden of every place which could be an annoyance to his new capital. Before the close of 1713 Stralsund was the only spot in Pomerania remaining to the Swedes: Peter himself gave the plan for its siege, and then leaving Menzikoff to carry it out, went to St. Petersburg, and from thence with a squadron of galleys and flat boats made himself master of Abo and the whole coast of Finnland. The library of Abo was transferred to St. Petersburg, and was the foundation of the present library of that city.

He next defeated the Swedish fleet in a naval engagement, and instituted the female order of St. Catherine on the occasion, in honour of the czarina, who alone could bestow it. The senate was removed from Moscow to St. Petersburg in 1713, and the emperor's summer and winter palaces were completed in 1715. He employed about 40,000 men in finishing his dockyard, building ships, wharfs, and fortifications. Goods imported into Archangel were prohibited from being sent to Moscow; and under these favourable circumstances, St. Petersburg soon became a place of great commerce and wealth.

Peter had now taken the whole of Finnland, and the provinces of Esthonia and Livonia, and having nothing to fear from Charles XII., he made a second tour through Europe in 1716, accompanied by the empress. They visited Mecklenburg, Hamburg, Pyrmont, Schwerin, Rostock, and Copenhagen, where he remained some months. While he was at Copenhagen, an English and a Dutch squadron arrived: Peter proposed that the four fleets should unite, and proceed to sea in search of the Swedish fleet: the chief command was given to the Czar, who declared the moment in which he hoisted his standard to be the proudest of his life. From Copenhagen he went to Lübeck, where he had an interview with the king of Prussia, and then to Amsterdam, where he remained some time. Catherine, who had been left behind, was brought to bed at Wesel of a third child, which died the next day. She remained at Amsterdam while her husband went to Paris, where he was received with great splendour. On his return to Amsterdam he visited Berlin on his way to Russia. During this tour he purchased great quantities of pictures, cabinets of birds and insects, books, and whatever appeared likely to enrich or ornament the city of his creation. The king of Denmark presented him with a great hollow globe eleven feet in diameter, whose inside represented the celestial and the outside the terrestrial sphere. Peter showed everywhere the same dislike to parade and formal etiquette which he had always evinced, and avoided them when possible.

His eldest son, Alexis, who had unhappily been left to the guardianship of his mother, had always been a source of disquietude and trouble to Peter; and when he grew up, far from showing any desire to tread in the footsteps of his father, he chose his friends and advisers from among the disaffected and turbulent boyars and priests, who were opposed to all change. The unfortunate princess, wife of Alexis, had fallen a victim to the brutal conduct of her husband, after giving birth to a son, Peter Alexiovitz, afterwards Peter II. While yet grieving for the loss of his daughter-in-law, Peter remonstrated with his son on his conduct, and told him that he should not be his successor unless he altered his mode of living. These remonstrances being treated with complete neglect by Alexis, who still pursued his vicious courses, Peter forced him, on the 14th Feb., 1718, to sign and swear to a deed wholly renouncing the succession to the crown: he also required from him the names of his advisers in his misconduct. The answers given by Alexis to the queries put to him were such, that Peter thought it necessary to try him by the great officers of state, the judges, and the bishops, who unanimously condemned him to death. On the day of his condemnation, he was seized with a violent illness, which terminated in two days, on the 7th July, 1718. His mother was strictly confined, and his advisers punished. In 1719 the Czar's son by Catherine, in whose favour Alexis had abdicated, died at five years of age. On the 10th September, 1721, the peace of Neustadt was concluded, by which Sweden ceded to Russia, Livonia, Esthonia, Ingria, Carelia, Wyburg, and the adjacent islands, but secured the possession of the Gulf of Finland.

Peter had now attained the summit of his glory: he was requested, and after some hesitation consented, to adopt the titles of 'Peter the Great, Emperor of all the Russias, and Father of his Country.' This was done amidst great rejoicings, which continued for fifteen days. He now turned his undivided attention to the arts of peace. He commenced canals to unite navigable rivers; encouraged by bounties the manufactures of woollen and linen cloths; the erection of corn, powder, and sawing mills; established a manufactory of small-arms; instituted hospitals, and established a uniformity of weights and measures; paved the streets of Moscow and St. Petersburg; and ordered the young nobility to carry their wives to visit foreign courts and countries, in order to acquire more civilised manners. Some of his measures were not so politic, although equally well intended, such as the attempt to fix the prices of provisions and the limit of expense in dress.

In 1722, Peter led an expedition to the Caspian, which however failed in producing any results. In 1723 he went to St. Petersburg to found the Academy of Sciences, and to erect a memorial of the establishment of a navy in Russia. Peter took his idea of the academy from that of Paris, of which he had been elected a member during his visit to that capital. In the same year he caused Catherine to be crowned, and his eldest daughter was married to the duke of Holstein Gottorp. He suffered greatly at this time from a strangury in the neck of his bladder, which painful disorder he endeavoured to stifle by an unlimited indulgence in strong liquors, which so much increased the violence of his temper, that even the empress is said to have feared his presence. Being partially relieved, he went, in October, 1724, contrary to the advice of his physicians, to inspect the works on Lake Ladoga. On his return he proceeded to Lachta, on the Gulf of Finnland, and had scarcely anchored there, when a boat full of soldiers being cast on the shore, Peter, in his ardour to assist them, waded through the water, which brought on violent inflammation in the bladder and intestines. He was conveyed to St. Petersburg, where his complaint made rapid progress, giving him intense and constant pain. He at length sunk under the disease, and expired on the 28th of January, 1725. His body lay in state till the 21st March, when his obsequies and those of his third daughter, Natalia Petrowna, who died after her father, were performed at the same time.

Peter I., deservedly named the Great, was compounded of contradictions; the greatest undertakings and the most ludicrous were mingled together; benevolence and humanity were as conspicuous in him as a total disregard of human life; he was at once kind-hearted and severe even to ferocity; without education himself, he promoted arts, science, and literature. 'He gave a polish,' says Voltaire, 'to his people, and was himself a savage; he taught them the art of war, of which he was himself ignorant; from the sight of a small boat on the river Moskwa he created a powerful fleet, made himself an expert and active shipwright, sailor, pilot, and commander; he changed the manners, customs, and laws of the Russians, and lives in their memory as the *Father of his Country*.'

Menzikoff, whose birth was so obscure as to be totally unknown, and who had risen through the favour of the Czar to be a prince and governor of St. Petersburg, caused Catherine to be proclaimed empress immediately after the death of Peter, and during her reign possessed unlimited power. Catherine died of a cancer in the breast, aggravated by excessive indulgence in wine of Tokay, in 1727, at the age of 38, having survived her husband only two years and a few months. She was succeeded by Peter II., son of the unfortunate Alexis. He was left in the guardianship of Menzikoff, who affianced his daughter to the young Czar. Peter felt the greatest repugnance to her, and in consequence, with the help of Dolgorouki, his tutor, caused Menzikoff to be arrested and banished to Siberia. His great wealth was forfeited, and he was only allowed out of it 10 rubles a-day for his support. He died at Berezof, in 1729. The haughty favourite of Peter the Great, whose magnificence exceeded that of crowned heads, died in poverty and exile.

Among other works connected with the mechanical arts, Peter the Great translated 'L'Architecture de Sebastien Leclerc;' 'L'Art de Tourner, par Plumier;' 'L'Art des Ecluses et des Moulins, par Sturm.' The manuscripts of these, with his journal of the Swedish campaigns from 1698 to 1714, are preserved at St. Petersburg.

PETER II. [Russia.]

PETER III. [Russia; Catharina ii.]

PETER THE HERMIT. [Crusades.]

PETER-HOUSE, the earliest endowed college in the university of Cambridge, was founded in 1257, by Hugh de Balsham, then sub-prior, afterwards bishop of Ely, who, having purchased two hostels, one of them belonging to the Friars of Penance, united them, and appropriated the building for the residence of students; but it was not till 1280, after his promotion to the see of Ely, that he endowed the college with revenues for the support of a master, fourteen fellows, two bible-clerks, and eight poor scholars. After his death a new college was built on the site of the two hostels, for which purpose the bishop gave by will the sum of three hundred marks; he gave them also the church of St. Peter. Among the principal benefactors in subsequent times were Simon Langham, bishop of Ely, who gave the rectory of Cherry-Hinton; bishop Montacute, who appropriated the church of Triplow, and gave the manor of Chewell in Haddenham; Margaret lady Ramsay, who founded two fellowships and two scholarships, and gave two advowsons; and Dr. Hale, one of the masters, who gave the sum of 7000*l.* and two rectories.

The fellowships are open without restriction to natives of any part of the British dominions, but no one is eligible who is M.A., or of sufficient standing to take that degree. The bishop of Ely appoints to the mastership one of two candidates presented to him by the society. The candidates must be doctors or bachelors of divinity, and must be selected if possible from the fellows on the foundation. Formerly there could not be more than two fellows of a county (except of Cambridge or Middlesex), and seven fellowships were confined to the northern and seven to the southern division of England and Wales; but these restrictions were removed by letters-patent, which came into operation in June, 1839.

One-fourth part only of the foundation fellows are required to be in priest's orders. By queen Elizabeth's licence the five senior clerical fellows may hold any livings with their fellowships, provided they are not more than 20*l.* in the *Liber Regis*, and within twenty miles of the university of Cambridge. The bye fellowships, which are perfectly open and unrestricted, are distinct from the former; the possessors of them are not entitled to any office or voice in the affairs of the college. Two were founded 1589, by Andrew Perne, D.D.; two, in 1601, by Lady Ramsay; and four, in 1637, by Thomas Parke, Esq.

Two fellowships of 70*l.* per annum each, and four new scholarships of 30*l.* per annum each, have recently been added to the college from the donation of the Rev. Francis Gisborne, M.A., late fellow of Peter-House. This foundation bears the name of the donor. The two Gisborne fellowships are tenable for seven years, and any person may be elected from either of them into a foundation fellowship before he is of standing to take his M.A. degree. These fellowships are vacated by marriage, or by the possession of any permanent income amounting to 250*l.* per annum.

The rest of the scholarships, fifty-eight in number, of different value, are paid in proportion to residence. A few of them are in the patronage of Lord Melbourne, and preference is given to scholars of Hertford school.

The livings in the gift of this college are, the rectories of Glayston in Rutlandshire, Statherne in Leicestershire, Exford in Somersetshire; Norton, Witnesham, Newton, and Freckenham, in Suffolk; and Knapton in Norfolk; with the vicarage of Hinton, and the curacy of Little St. Mary, Cambridge, in Cambridgeshire; and the vicarage of Ellington in Huntingdonshire. Glayston rectory is annexed to the mastership, and the vicarage of Hinton and the curacy of Little St. Mary are tenable with fellowships.

This college stands on the west side of Trumpington-street, and consists of two courts, the larger of which is 144 feet by 84. The chapel, which stands in the lesser court, was built in 1632. The master's lodge is a detached building on the opposite side of Trumpington-street.

The bishop of Ely is the visitor of this college. The number of members upon the boards, March 18th, 1840, was 210. Copies of the statutes of this college are preserved among the Harleian MSS. in the British Museum.

(Lysons's *Magna Britann.*, 'Cambr.,' pp. 103, 104; *Camb. Univ. Calendar*, 1840.)

PETER PENCE, a tax antiently levied throughout England, according to some authorities, of a penny upon each house; according to others, of a penny upon every house which contained twenty pennyworth of any kind of goods, and paid to the pope. This payment, in antient times, passed under various denominations: Rome-fee, Rome-penning, and Rome-scot were the Saxon names; Denarii S. Petri and Census S. Petri, in Latin. The earliest payment of it is attributed by some to Ina, king of the West Saxons, A.D. 720; by others to Offa, king of Mercia, A.D. 790. At one period of his reign, Edward III. discontinued this payment, but it was revived by Richard II. It finally ceased at the Reformation. (Du Cange's *Glossary; Hist. Will. Malmsb. Leg. Edw. Conf. & Will. Conq.*)

PETER'S RIVER, ST. [Mississippi, River.]

PETER'S, ST. [Rome.]

PETERBOROUGH, or **PETERBURGH,** an English city, in the liberty of Peterborough (otherwise called Nassburgh or Nassaburgh soke or hundred), in the county of Northampton, on the river Nene, and on the Hull and Lincoln mail road, 83 miles from the General Post-office, London, by Waltham Cross and Baldock.

This city owes its origin to a celebrated Benedictine abbey founded by Peada, son of Penda, king of the Mercians, soon after the revival of Christianity among the Saxons. Peterborough was antiently called Medeshamsted and Medeswellehamsted. About the year 870 the abbey was destroyed by the Danes; and after remaining desolate for a century, was restored in the reign of Edgar (A.D. 970), about which time the name Medeshamsted was superseded by that of Burgh, otherwise Gilden-burgh, from the wealth and splendour of the abbey, or Peter-burgh, from the saint to whom it was dedicated. In the reign of William the Conqueror the abbey was attacked and plundered by the insurgents of the fens under Hereward-le-Wake; and the village which was rising around it was destroyed by fire. In 1116 the village and the greater part of the abbey were again destroyed by fire. The monastic buildings were gradually restored and augmented; and at the dissolution of the religious houses under Henry VIII., Peterborough was one of the most magnificent abbeys then existing. Having been selected as the seat of one of the new bishoprics erected by Henry, the buildings were preserved entire. In the civil war of Charles I. great devastations were committed. The cathedral itself was much injured, and many of the other conventual buildings were utterly demolished and the materials sold. The Lady-chapel was subsequently taken down by the townsmen, to whom the church had been granted for a parish church. No historical interest is attached to the town independent of the abbey or cathedral.

Peterborough is comprehended in the parish of St. John Baptist, which has a total area of 4880 acres, and a population, in 1831, of 6313: of this the limits of the city comprehend an area of 1430 acres, and a population of 5553; the remaining area and population are included in the hamlets of Dogsthorpe and Eastfield with Newark, and the chapelry of Longthorpe. The city consists of several streets regularly laid out and well paved and lighted, close upon the bank of the river, over which there is a wooden bridge. The houses are in general well built, and several of them are of recent erection. Besides the cathedral, there is a large parish church; and also some dissenting places of worship. There is a market-house, the upper part of which is used as the town-hall; and a small gaol and house of correction for the liberty.

The cathedral of Peterborough is a regular cruciform structure of Norman or early English character, remarkable for the solidity and massiveness of its construction. The erection of it was commenced A.D. 1117 (after the great fire of 1116), by John de Sais or Seez, a Norman, then abbot. It is probable that the choir was the part first erected. It has a semicircular eastern end, and at the extremities of the semicircle there are two slender turrets crowned with pinnacles: the aisles have subsequently been carried out square by an addition of perpendicular character. The chancel was finished (A.D. 1140) by Abbot Martin de Vecti: the great transept and a portion of the central tower were built by Abbot William de Waterville or Vaudeville (A.D. 1160-1175), and the nave by Abbot Benedict (A.D. 1177-1193). The central tower is low, and forms a lantern. The nave has its piers composed of shafts of good proportions and fine appearance, without that overwhelming heaviness which appears in buildings where the great circular piers are used. At the western end of the nave are smaller transepts: over the north-western transept is a tower of early English character, with angular buttresses surmounted with pinnacles, and formerly with a spire. It was obviously part of the architect's plan to erect a similar tower over the south-western transept, but it was never completed. The fine western front of the cathedral is an addition to the nave; it consists of a lofty portico of three compartments, that in the centre being the narrowest; each compartment has an arch equal in height to the nave, supported by triangular piers faced with clustered shafts, and is surmounted by a lofty and richly ornamented pediment and a cross. At each extremity of the western front is a lofty turret flanked at the angles by clustered shafts and pinnacles, and crowned with spires. The fine effect of this western front is much injured by a small porch or chapel inserted in the central arch between the piers, which, though in itself very beautiful, is here quite misplaced.

Though the general character of the architecture is Norman or early English, great alterations have been made in later styles. Nearly all the windows have had tracery inserted, and some of them have been enlarged. The perpendicular addition at the eastern end, by which the aisles of the choir have been carried out square, is plain in its outward appearance, with large windows and bold buttresses, the latter surmounted by sitting statues in place of pinnacles. The ceiling or inner roof of the nave and of the great transepts is painted wood; and the choir has a wooden groined roof of very inferior workmanship and appearance. The dean and chapter have recently erected a new organ-screen of stone, and entirely new fitted up the choir with stalls, throne, pulpit, and altar-screen. The organ-screen consists of an entrance into the choir under a richly moulded pointed arch surmounted by a crocketed canopy. The whole of the fitting up of the choir is in the style of the time of Edward III., and the wood-work is of oak richly ornamented. There are few monuments, shrines, or chantry chapels, the devastations of the parliamentary troops having deprived the church of many of its ornaments of this class. The burial-places of the two queens, Catherine of Aragon and Mary of Scotland, both of whom were interred here, are unmarked by any sepulchral monument.

The dimensions of the church are given by Bridges (*Hist. of Northamptonshire*) as follows:—total length 476 ft. 5 in., breadth of the nave and aisles 78 ft., height of the ceiling of the church 78 ft., breadth of the church at the great transepts 203 ft., breadth of the transepts 69 ft., height of lantern 135 ft.; all these are (we believe) inside measurements. Length of the western front 156 ft., height of the turrets at the extremities of the west front 156 ft., tower and spire (the latter since taken down) over the north-west transept from the ground, 184 ft., height of the central tower from the ground 150 ft.; these are all outside measurements.

The view of the cathedral is confined on every side except the west, at which end is a large court, the entry to which from the town is by a gateway of Norman architecture, with some later additions. On the south side of the court is a range of the antient monastic buildings, retaining much of their antient appearance, and having in the midst of them the tower-gateway to the bishop's palace, over which is the knight's chamber. On the greater part of the other sides the cathedral is surrounded by the antient cemetery of the citizens, which is filled with tombstones. The gate of entrance to this cemetery from the western court is by a late perpendicular gate, remarkably rich in ornament. This cemetery is now not used; and a new burial-ground has been formed on the western side of the city.

The trade carried on at Peterborough is chiefly in corn, coal, timber, lime, bricks, and stone. The Nene is navigable for boats. There is a weekly market, and there are two yearly fairs; one of these, called 'Brigge fair,' is kept over the bridge on the Huntingdonshire side of the river.

There is no corporation at Peterborough. The dean and chapter exercise a certain jurisdiction; their steward holds a court for trying all actions, personal or mixed, arising within the city, but suits above 5*l.* are seldom tried here. The writs issuing from this court are directed to the bailiff of the city, who is appointed by the dean and chapter. Quarter-sessions for the liberty of Peterborough (which includes the whole soke or hundred of Nassaburgh) are held for trying criminal actions of all kinds; the *Custos Rotulorum*, who is appointed by the crown, presides. The gaol and house of correction for the city and liberty are both miserably deficient. (*First Report of Inspectors of Prisons in Great Britain.*) Prisoners committed for trial for capital offences are sent to Northampton.

Peterborough has sent members to parliament from 1 Edw. VI. (A.D. 1647). The boundary of the city for parliamentary purposes was enlarged by the Boundary Act, so as to comprehend the whole parish of St. John the Baptist and the Minster precincts, which are extra-parochial. The bailiff of the city is the returning-officer. The number of voters registered in 1835-36 was 578.

The living of St. John is a vicarage including the chapelry of Longthorpe, of the clear yearly value of 575*l.*, with a glebe-house. It is in the gift of the bishop of Peterborough.

There were in the parish, in 1833, one infant-school, with 68 children; the endowed cathedral grammar-school, with 31 boys; two endowed schools, with 20 and 16 boys respectively; a national school, with 322 boys and 118 girls, thirteen other boarding or day schools, with 182 boys and 190 girls; and two Sunday-schools, with 93 boys and 91 girls.

The bishopric of Peterborough was erected by Henry VIII.; the diocese, which was taken out of that of Lincoln, comprehends the counties of Northampton and Rutland, except three parishes in each county, which remain in the peculiar jurisdiction of Lincoln. There are two archdeaconries, Northampton and Leicester: that of Northampton comprehends the ten rural deaneries of Brackley, Daventry, Haddon, Higham Ferrars, Northampton, Oundle, Peterborough, Preston, Rothwell, and Weldon, all in Northamptonshire; the five rural deaneries of Alstow, East Hundred, Oakham soke, Rutland or Martinsley, and Wrandike, all in Rutlandshire; the archdeaconry of Leicester (lately in the diocese of Lincoln) contains the seven rural deaneries of Akeley, Framland, Gartree, Goodlaxton, Goscot, Leicester, and Sparkenhoe.

The average yearly revenue of the bishopric is returned at 3518*l.* gross, and 3103*l.* net, including the preferments annexed to the see. The average yearly revenue of the cathedral is returned at 6357*l.* gross, and 5118*l.* net. The corporation consists of the dean and six prebendaries; there are four minor canons, and a precentor, who is also sacrist and librarian. The dignitaries have no separate revenues.

PETERBOROUGH, LORD. [MORDAUNT.]

PETERS, BONAVENTURA, one of the most eminent marine painters of the Low Countries, was born at Antwerp in 1614. The subjects which he in general preferred were storms at sea, 'in which,' says Pilkington, 'he represented with extraordinary truth and pathos the various circumstances that can fill the mind with pity and terror. The raging of the waves, the impending tempest, vessels foundering or dashed in pieces against rocks, the mariners perishing in the deep, or seeming to dread a lingering death on a desert shore, are expressed by his pencil with the utmost truth, nature, and probability.' Sometimes however he painted calms and views of castles, or towns on the sea-shore, with equal merit. There is the same light and spirited touch, the same transparency in his colouring, and his water, whether agitated or still, has equal truth and delicacy. The figures are extremely well designed and exquisitely finished. In a few of his works (which perhaps are erroneously ascribed to him) the colouring is too coarse, and the draperies of the figures mingled with tints that do not harmonise with the whole. His best works are extremely valuable and scarce, for he died, in 1652, at the early age of thirty-eight years.

Peters, John, brother of Bonaventura, was born at Antwerp, in 1625. He painted the same subjects as his brother, which are as finely touched, as well coloured, as transparent, and enriched with excellent figures. His sea-fights were much admired; and he also painted views of villages, towns, and fortresses on the banks of rivers, which he designed after nature.

PETERSBURG, ST., a government of European Russia, extends from 57° 56′ to 60° 35′ N. lat. and from 21° 5′ to 33° 52′ E. long. It is formed of the antient province of Ingermannland, or Ingria, a part of Carelia, and some circles formerly belonging to Novogorod. It is bounded on the north by the Gulf of Finnland, Finnland, and Lake Ladoga; on the east by Novogorod; on the south by Pskow; and on the west by Lake Peipus and Esthonia.

Face of the Country; Soil; Climate.—The country is for the most part level, and in the north-east part it is low, and full of swamps and morasses. In the south it is rather more elevated; a long range, called the Duderhoff mountains, which in fact are only low hills, nowhere rising more than 240 or 300 feet above the level of the sea, covers this part of the country. The government contains many forests, and only here and there some good arable land. The soil in the eastern, southern, and western circles, even on the Gulf of Finnland, is partly sandy, partly clayey, with extensive morasses and forests, which, together with the lakes, cover two-thirds of the surface. The principal lakes are the Ladoga, Peipus, and Pskow: and the chief rivers are the Neva, the Luga, the Narova, and the Wolchow. The Neva issues from Lake Ladoga, near the fortress of Schlusselburg, from which point to its mouth is only 40 wersts in a straight line, but owing to the bend which it makes towards the south, the whole course is 60 wersts (40 English miles) to the bay of Cronstadt, which ought to be considered as the mouth of the river, for the water is sweet and fit for drinking as far as Cronstadt. The banks are rather elevated; the breadth varies from 600 to 1200 feet, and the water is remarkably pure, light, and limpid. Within the city of St. Petersburg it divides into several branches. The climate is cold, damp, and not favourable to agriculture. The summer is short, but in general fine and often very hot: thunder-storms are neither frequent nor violent. The area of the government, according to Schubert, who is followed by Storch, Wichmann, and others, is 17,800 square miles; Arsenieff makes it 16,400, Köppen 18,500, and Hörschelmann 18,600. It is divided into nine circles. The population, in 1838, was 890,000. Though the climate is so unfavourable, and a large portion of the government covered with marshes, the crops raised are by no means scanty, though they are not sufficient for the supply of the great population of the capital. Flax and hemp are not much cultivated; fruit-trees do not thrive in the open air. There are however in the vicinity of St. Petersburg fine gardens and parks; kitchen-gardens, which produce vegetables in abundance, and numerous hothouses which supply the capital with pines, melons, pine-apples, asparagus, &c. Timber is still the chief source of wealth, for the forests, though much injured by waste and bad management, are still of immense extent. In the forests vast quantities of berries, wild fruits, and mushrooms are found. There is no game except hares. The country-people rear great numbers of geese, ducks, and turkeys for the markets of St. Petersburg. Fish are tolerably abundant. The breeding of cattle is very limited on account of the cold. The mineral kingdom affords granite, limestone, marl, brick earth, potters' clay, &c. The villagers manufacture wooden wares of various kinds. Trade and manufactures are almost wholly confined to the capital: there are however considerable manufactories of cloth, camlet, and blankets, as well as several glass-houses at Jamburg, on the Luga, with 2000 inhabitants; and of printed calico at Schlusselburg, on an island where the Neva issues from Lake Ladoga. Gatschina, situated on a beautiful lake formed by the Ischora, has 7000 inhabitants, a military orphan-house, and a foundling hospital. [NARVA; CRONSTADT.]

PETERSBURG, ST., the second capital of the Russian empire (Moscow being accounted the first), is situated in 59° 56′ N. lat. and 30° 18′ E. long., at the eastern extremity of the Gulf of Finnland, and at the mouth of the river Neva. Of all the capital cities of Europe, St. Petersburg has at first sight the most striking appearance: the breadth and cleanliness of the streets, the elegance of the buildings, the noble canals which traverse the city, and the regularity of the edifices on their banks, make altogether a most impressive spectacle. 'The united magnificence of all the cities of Europe,' says Dr. E. Clarke (since whose time it has been very much improved), 'could but equal St. Petersburg.' There is nothing little or mean to offend the eye; all is grand, extensive, large, and open; the streets seem to consist entirely of palaces; the edifices are lofty and elegant. The public structures, quays, piers, ramparts, &c., are all composed of masses of solid granite, and our admiration is increased when we reflect that not a century and a half has elapsed since its foundation. In 1703 Peter the Great chose this spot, then just taken from the Swedes, for the site of a fortified seaport. It was a low marshy island, covered in summer with mud, and in winter a frozen pool. The adjacent country was covered with marshes and impenetrable forests, the haunts of bears and wolves. We cannot suppose that Peter had any idea of fixing the seat of his empire on this extreme frontier, but it was important to have a strong position as a check upon the Swedes: this was also the only place through which an intercourse could be established with civilised Europe, an object which he had much at heart. In fact he was probably aware that the fort which the Swedes had built about five miles from the mouth of the Neva, at the place where it receives the little river Ochta, and which they called Nyenschanz, besides its importance as a military station, and as the key of the country, was not less important as a commercial place, during the connection of Novogorod with the Hanseatic league, especially in the sixteenth century. Under Alexis Michailovitsch the fort and the town were almost wholly destroyed by fire, and Nyenschanz was only a good military position, but an insignificant town when Peter the Great made himself master of it in 1702, after a few days' siege. The habitations supplied materials for the houses of St. Petersburg.

The Neva, on the banks and islands of which the city is built, runs first towards the north, and then turning to the west, sends out towards the north an arm called the Nevka, which again divides into two branches called the Great and the Little Nevka. The main river, after throwing out the Nevka, divides into two branches, the Little Neva, which runs north-west, and the Great Neva, which runs south-west. Thus the Gulf of Cronstadt receives the Neva by four great arms, which form several islands. The island to which the name of St. Petersburg was first given, lies on the north side of the river between the Nevka and the Little Neva; and on a small island in the Great Neva, between these two arms, Peter laid the foundations of a fortress, which however was not completed till 1740. The difficulties to be overcome were immense. In the spring of 1703 he collected a number of Russian, Tartar, Cossack, Calmuck, Finnish, and other peasants, and workmen were sent for from all parts of the empire. Peace not being yet concluded, soldiers were encamped on both sides of the Neva. The great difficulty was to find subsistence for so many persons. The surrounding country was desolated by a long war, and provisions were very scarce and dear. The workmen, being exposed to the cold and the damp, often up to their shoulders in the water, perished from fatigue and want, and the foundation of St. Petersburg cost the lives of one hundred thousand men.

The city, in its present state, is of a circular form, but rather irregular. The circuit is about eighteen miles, but the smaller portion of the area is covered with buildings. The most considerable and the handsomest portion is the southern, on the left bank of the Neva, including the four Admiralty quarters; between this and the northern or right bank of the Great Nevka, lie, from south to north, 1, Wassily-Ostrov; 2, St. Peter's Island, the Island of Petrovsky, and the Apothecaries' Island; 3, Kammenoi-Ostrov, Krestovsky, and Yelagin, a group of islands covered with gardens, groves, avenues of trees, and country-houses, which in summer are the resort of the rich. The city is divided into twelve districts, and these again into quarters. Few cities have such long and broad streets as St. Petersburg. They are from 60 to 120 feet broad; and the Nevsky Perspective is 14,350 feet long, the Great Perspective 10,220, and eight others 6000. The stone pavement is in general bad, and must be laid down afresh every year; a pavement of hexagonal blocks of wood, covered with tar, has been found to be more durable and cheaper, and is now used in many of the principal streets, which have broad flag-pavement for the foot passengers. There are no wells, but the water of the Neva is remarkably clear, pure, and wholesome. Those who live at a distance from the river use the water of the canals, the principal of which are the Fontanka, surrounding the whole Admiralty quarter, and, within it, the Catherine Canal and the Moika. There are two bridges of boats over the Neva, and three over its arms; one of them, the Troitskoi or Suwaroff Bridge, is 2456 feet long. These bridges are all removed whenever danger is apprehended from the ice, both at the beginning of the winter and in the spring. There are above seventy bridges over the canals, many of which are of granite, and ten of cast-iron, two of which are handsome suspension bridges, and many of wood. The Great or Southern Neva is here from 900 to 1200 feet wide, and its south or left bank, to the extent of 10,000 feet, exclusive of the Admiralty, which divides it into two parts, is furnished with a quay of granite, a work which, for utility and magnificence, will remain a lasting monument of the reign of Catherine II. The bank is raised on piles ten feet above the level of the water, and has a foot-pavement seven feet broad, a breastwork two feet and a half high, and, at convenient distances, double flights of steps for landing, with semicircular seats at the top, all of granite. The part of the quay to the east of the Admiralty is called the Quay of the Court, and that on the west 'The English Quay,' being lined with a row of houses chiefly inhabited by opulent English merchants. The Quay of Wassily-Ostrov, on the opposite bank, which was completed in 1834, is still finer, but not so extensive. It is adorned with two colossal sphinxes, brought from Egypt, which are placed in front of the Academy of Arts. There are 140 Russian-Greek churches, 40 of other Christian communities, 2 Greek convents, a synagogue, and a mosque. Divine service is performed in fifteen languages. Of the Greek churches the most remarkable are, 1, the Isaac's Church, which when finished will be the most magnificent—it is to be built entirely of marble; 2, the beautiful cathedral of the Mother of God of Casan; 3, the church of St. Nicholas; 4, the church of Alexander Nevsky, in the convent of the same name, containing the body of the saint in a silver sarcophagus (the convent is the residence of the archbishop of Petersburg, and contains an academy and a seminary, with a fine library); 5, the church of St. Peter and St. Paul, in the citadel, which contains the tombs of the imperial family. The number of magnificent palaces and public buildings is so great that we can do little more than barely enumerate the most remarkable:—1, The Imperial Winter Palace has been described as the most conspicuous by all travellers: it was entirely destroyed by fire, about three years ago, but is now rebuilt. It was fortunate that, by the great exertion of the imperial guard, the fire was prevented from extending to the Hermitage, built by Catherine, which contains a costly library, a valuable collection of paintings, and other treasures. 2, The Marble Palace, an elegant but gloomy-looking building. 3, The Taurida Palace, with its fine gardens, presented to Prince Potemkin by Catherine II. 4, The Anitchkov Palace, the residence of the emperor Nicholas while he was grand-duke. 5, The Old Michailov Palace, where the emperor Paul resided and died. 6, The New Michailov Palace, with a park, the residence of the grand-duke Michael. It was built between the years 1819 and 1825, and is one of the finest palaces in Europe. The number of what are called crown-buildings is very great. Among them are, 1, the Admiralty, surrounded on three sides by the dock-yards; 2, the splendid building belonging to the general staff; 3, in the very extensive Isaacs Square, the Senate House, the General Synod, the Palace of the War Department, the large and handsome riding-school of the guard; 4, the Alexander Theatre, in the Nevsky Perspective; 5, the fine palace of the Imperial Assignat Bank; 6, the New Arsenal; 7, the Gostinoi-Dvor, a great bazaar, two stories high, each containing 170 shops; 8, the Academy of the Fine Arts, &c. The Field of Mars, adorned with a statue of Suwaroff, is extensive enough to admit 40,000 or 50,000 men to be reviewed in it. The Field of Mars is bounded on two sides by the imperial gardens, on the third by the Winter Palace, and on the fourth by a row of massive buildings. The most recent of the public monuments is the Alexander Column, erected in honour of the emperor Alexander. There are also a celebrated equestrian statue of Peter the Great, a granite obelisk, 82 feet high, in honour of Romanzov, and the above-mentioned statue of Suwaroff.

The Russian sovereigns have done much to promote science and learning: academies and schools have been founded and liberally endowed by them, and learned men invited from foreign countries. Among these establishments are the university, founded in 1819, which has neither a theological nor a medical faculty; the academy of sciences, founded by Peter I., on the plan of Leibnitz; the academy of fine arts; the pedagogical institution for training teachers in the higher departments of learning; the ecclesiastical seminary in the convent of St. Alexander Nevsky; the medico-chirurgical academy; four gymnasia; the Oriental institution; numerous institutions for the army and navy; the mining academy; the female schools of St. Catherine; the Smolnoi convent, and the foundling hospitals. There are also a great number of private schools, and many private masters and governesses in families, who are mostly Germans. The collections of all kinds are very rich. The imperial public library consists of above 400,000 volumes; that of the academy of sciences, of 100,000; and almost every establishment has its own library. The principal collections are the zoological, the antiquarian, and that of Asiatic coins in the academy of sciences; the cabinet of coins of the Oriental institution; the splendid collection of minerals of the mining academy, in which there is a lump of pure native gold weighing 25 lbs. and a lump of platinum of 10 lbs.; the collections in the Hermitage, Romanzov's museum, the extremely rich collections of exotic plants in the hothouses of the botanic garden, and many private collections. The hospitals or charitable institutions of all descriptions are very numerous and well supported, rivalled perhaps only by those of London, the virtue of charity being one of the most prominent features of the Russian character. The number of houses in 1838 was 8665, of which 3243 were of stone, and the remainder of wood: this seems a small number in proportion to the population, but some of the houses are extremely large; in 1833 there were 13 houses each inhabited by above 1000 persons, 121 by 300 to 1000 persons, 223 by 200 to 300 persons, and 671 by 100 to 200 persons.

The ground on which St. Petersburg stands is low and swampy, and the surrounding country is a morass and forest, except where it has been ameliorated by industry and art. It has been calculated that, on an average of 10 years, there are 97 bright days, 104 rainy, 72 of snow, and 97 unsettled. The ice in the Neva never breaks up before the 22nd of March (once only on the 6th of March), nor later than the 27th of April; the earliest time of the river's freezing is the 20th of October, and the latest the 1st of December. The few bright days are generally during the greatest heat or the severest cold. The spring is very short; a sudden transition brings summer at once, which all classes hasten to enjoy, in the adjacent villas, in hospitality and social amusements. In summer the nights are bright and generally warm. During the night, parties, frequently attended by music, promenade the streets in every direction, and the simple melody of the popular ballads floats on the air, from the boats that glide on the canals and the smooth surface of the Neva. Charmed by the novelty and beauty of the scene, the stranger, expecting the approach of night, continues to linger till he is beguiled of his sleep, and sees with surprise the first beams of the rising sun gild the summits of the palaces and temples. In autumn St. Petersburg is one of the most disagreeable spots on the face of the earth. On the whole, winter is perhaps the best season; at least it has many advantages over the foggy winter of more southern climes. The cold, when it once sets in, is equal and constant, and it strengthens and braces the body. Travelling in sledges over the hard snow is convenient and agreeable; the Russians too know how to defend themselves against the cold better perhaps than any other people. All commercial intercourse with foreign countries being suspended during the winter, the citizens indulge their national fondness for luxury and amusements. The great masked ball (as it is called) on New Year's Day brings together persons of all classes in the Winter Palace: tickets are very easily obtained, and above 30,000 are usually issued. Nobody however is masked, nor is there any dancing. The river being frozen over for several months, the surface presents a scene like that which was exhibited when a fair was held on the Thames, nearly resembling Bartholomew fair. The populace are amused with swings, roundabouts, and the like, and above all by the ice-hills, which are inclined planes of considerable height, covered with blocks of ice. The ascent is by a flight of steps at the back. A low sledge with one person in it glides down the plane with such rapidity that it is carried by the impetus to the next ice-hill, when the driver takes his sledge on his back, ascends the steps, and descends on the other side. This is the favourite amusement of the Russians. There are likewise great popular amusements during Lent in Isaac's Square.

In summer all those who have the means go into the country. There are numerous country-houses in the islands, and on the road to Peterhof, Strelna, and Oranienbaum. Of the islands in the Neva, north of St. Petersburg, that of Krestovsky is the most beautiful; the isle of Yelagin has an imperial summer palace with a fine park. Kammenoi-Ostrov, another island, contains a palace belonging to the grand-duke Michael. Peterhof, on the bay of Cronstadt, the road to which is a noble causeway bordered by fine gardens and country-seats, has a large garden and fine waterworks. A grand fête is generally celebrated here on the 13th of July, in honour of the birthday of the empress Alexandra, when the gardens are splendidly illuminated and enlivened with bands of music, and above 100,000 persons are assembled. Oranienbaum, on the Gulf of Finnland, the summer residence of the grand-duke Michael, is still more beautifully situated than Peterhof. Zarskoje-Selo is a very magnificent imperial country-seat, with an immense park and noble gardens. A large portion of this palace was burnt down in 1820. At a short distance is the Pulkowaberg, on which the emperor Nicholas has caused a fine observatory to be erected, and furnished with the best instruments. Pavlovsk, near the town of the same name, is an imperial country-seat, with a fine park laid out in the English style by Brown.[*] At Gatschina, Tschesme, and Strelna there are likewise country-seats belonging to the Imperial family. [CRONSTADT; NARVA.]

According to the account given by the chief of the police for 1839, the population amounted in that year to 476,386, of whom 338,512 were males and 138,874 females: in 1838 the total was 469,720, so that there was an increase in 1839 of 6666. It appears from M. Köppen, that of the 469,720 inhabitants, in 1838, there were in the city and its district, including Cronstadt, only 53,883 males who had their legal settlement there. Supposing the total to be 109,000, including females, there remain 360,000 strangers from other provinces, of whom the great majority are males. We quote from the official tables a few instances:—

	Men.	Women.
Persons not of noble birth	19,210	9,687
Artisans included in the guilds	19,238	3,692
The garrison, not including the officers	48,406	10,336
Domestics	52,357	14,674
Workmen of the class of peasants	103,237	23,076

St. Petersburg is not only the capital but the greatest manufacturing city of the empire. There are above two hundred manufactories of different descriptions, some carried on by private individuals, of silk, cotton, woollen, leather, glass, gold and silver articles, watches, surgical instruments, paper, snuff and tobacco, sugar, &c. There are others which the government has considered it advisable to carry on upon its own account; such are the great manufactory of tapestry, a large manufactory of aqua-fortis, with an assay-office and a mint; a plate-glass manufactory, which produces mirrors 14 feet high and 7 feet wide, a porcelain manufactory, and a great manufactory of cotton and linen, in which steam-engines are employed, at Alexandrovsk, near the city; a considerable part of this manufactory was last year destroyed by fire. The government has likewise a cannon-foundry and powder-mills.

The commerce of St. Petersburg is very considerable. Cronstadt is the harbour. The following is the official account for the year 1839:—arrived at Cronstadt, in 1839, 1378 ships, of which 912 with cargoes and 466 in ballast; 1395 sailed, of which only 27 were in ballast—of these 50 had wintered at Cronstadt; this year only 33 remained to winter. Above 700 of these ships were English. The steam-boats to Lübeck performed twenty-one voyages, those to London twelve, to Hâvre eight, and to Revel twenty-one. Above 12,000 barks bring to St. Petersburg from the interior articles of Russian produce and manufactures for the consumption of the capital and for exportation. The total value of the imports was 198,961,386 rubles (in bank assignats), and the value of the exports 132,018,295 rubles; total 330,979,681 rubles. Deducting 2,504,445 rubles, the value of the goods exported and imported by the captains of ships and passengers, the remaining operations were effected by 170 commercial houses, of which 94 transacted business under a million of rubles, and 76 above that amount. Three houses did business to the amount of more than seven millions, two of eight millions, three of ten millions, one of twelve millions, one of nineteen millions, and one of twenty-six millions. Among these eleven houses there is not one Russian name; they are all German and English, except one French. The exports are hemp, flax, tallow, leather, iron, tobacco, canvas, coarse linen, bees'-wax, linseed, linseed-oil, tar, potash, &c. The increased exportation of wool deserves to be noticed. From 1800 to 1814, the average annual quantity exported was under 20,000 poods; from 1814 to 1824, under 36,000 poods; from 1824 to 1834, 112,000 poods; and in 1838 it was 360,760 poods. The imports are colonial produce of all kinds, manufactures of silk, cotton, hardware, French wines, jewellery, and all articles of luxury and fashion. The immense preponderance of the trade with England is proved by the number of ships employed in it. The effects of a rupture with England may be inferred from the fact that in the year 1808, which followed the alliance between Alexander and Napoleon, concluded at Tilsit in September, 1807, the value of the imports fell to 1,152,000 rubles, that of the exports to 5,875,000 rubles, and the duties of customs from five millions to 918,000 rubles. The actual revenue now derived from the customs is about 50 millions of rubles.

(Schmidtlin, *La Russie et la Pologne;* Hörschelmann; Stein's *Handbuch; Conversations Lexicon;* Cannabich, *Lehrbuch der Geographie;* the *Russian Journal of Commerce*, and *Journal of the Department of the Interior;* and *Plan of St. Petersburg*, published by the Society for the Diffusion of Useful Knowledge.)

Though by no means so complete as could be wished, the following table will serve as an architectural synopsis of the more remarkable structures of St. Petersburg, few of which, it must however be confessed, are of high architectural quality, or calculated to stand the test of critical examination, although from their magnitude and general air of stateliness they produce a favourable first-sight impression on the stranger:—

Table of Public Buildings.

	Date.	Architect.	Remarks.
The Fortress	1706-40	Tressini	
Directory Senate	1710		Originally Prince Menzikov's palace.
Cathedral of St. Peter and Paul in Fortress	1712-27	Tressini	
The Foundry	1733	Schumacher	
Summer Palace	1742	Rastrelli	
Smolnoi Monastery, Church		Rastrelli	
St. Nicholas Morskoi	1743		
The Anitchkov Palace	1748	Rastrelli	
Winter or Imperial Palace	1754-62	Rastrelli	A very large but grotesque pile; burnt down December 1837; rebuilt 1839.
Marble Palace	1770-85	Grimaldi	
Hermitage, the Little	1775	Lamotte	
——— the Great	1775	Felten	
——— Theatre	1782	Quarenghi	Interior, plan of an antient theatre. Order Corinthian.
Nevsky Monastery Church	1776-90	Starov	
Old Arsenal	1776		Hexastyle Doric in centre.
Colossal equestrian statue (Peter the Great)	1782	Falconet	
Taurida Palace	1783	Starov	
Obutchov's Hospital	1783		
Manège of the Imperial Guards		Quarenghi	A Roman Doric octastyle portico entire width of front. Sculptured pediment; ditto frieze within portico.

---

[*] The construction of an iron rail-road from St. Petersburg to Pavlovsk and Zarskoje-Selo has greatly increased the number of visitors to those places.

	Date.	Architect	Remarks.
Gostinoi Dvor, or Bazaar	1785		
Academy of Fine Arts	1788	Kakorinov	A very handsome structure. A Roman Doric order on a lofty arcaded basement.
Cathedral of St. Alexander Nevsky	1790	Starov	
Imperial Library	1795	Sokolov and Rusca	Ionic on basement.
Marine Cadets' College	1796		
Palace of St. Michael	1797-1800	Brenna	Italian style. Now used for the engineer corps.
Catholic Chapel, Knights of Malta	1798	Quarenghi	Order Corinthian; front four attached columns beneath pediment.
Imperial Bank		Quarenghi	
Institut Demoiselles Nobles, Smolnoi Monastery		Quarenghi	Front 730 feet; centre Ionic octastyle on basement.
Foundling Hospital on the Moika	1798		
Medical, &c. Academy	1799	Porta	Corinthian portico.
Troitzki Church			Byzantine style.
Romanzov Obelisk	1799	Brenna	Bronze. Height 82 feet.
Academy of Sciences	1799	Zakharov	Octastyle Ionic portico.
Admiralty	1801	Zakharov	A most extensive range of buildings of rich design.
—— Chapel		Montferrand	
The Casan Cathedral	1801-11	Voronikhin	Corinthian hexastyle [see PORTICO, Plans], with curved colonnades extending from it.
Russian Academy		Melnikov	
Imperial Hospital for Sick Poor	1803	Quarenghi	Octastyle Ionic portico.
Great Theatre	1804	Thomond	Ditto.
Birzha, or Exchange	1804-10	Thomond	Roman Doric, peripteral decastyle, with two rostral columns in front.
New Arsenal	1808	Dimertzov	
St. Sergius' Church		Dimertzov	
Salt Magazine		Volkhov	
Church of St. Vladimir	1811		
—— St. Peter	1817		
—— St. Catherine, Vassili Ostrov		Mikhaelov	Corinthian hexastyle portico. Dome.
—— Imperial Mews		Trombara	
Isaac's Church (rebuilding)	1818	Montferrand	
Church of the Skorbyashtnik (or Sufferers)	1818	Rusca	Front, Ionic hexastyle, attached columns. Interior a rotunda with 24 columns.
Grand-duke Michael's palace	1819-25	Rossi	Corinthian order on basement. Centre an octastyle prostyle.
Hôtel des Mines, or Mining Academy	1819		
The Etat Major	1821-30	Rossi & Bruilov	
The Hall of Archives		Rossi & Clarke	Entirely constructed of cast-iron. Style Gothic. Dimensions 142 by 57 feet.
Theatre, Aplugin Island	1826	Montferrand	
Narvsky Gate, or Triumphal Arch	1831-3	Quarenghi	Previously designed by Quarenghi, and erected temporarily in timber; now executed in metal by Clarke and Pratt.
Alexandrinsky Theatre	1832	Rossi	
Lutheran Church of St. Peter and St. Paul	1832	Bruilov	
Alexander Column	1832	Montferrand	Shaft a granite monolith, 84 feet high, surmounted by a colossal figure of Faith.
Church of St. Catherine the Martyr	183	Const. Thon	
Michailovsky Theatre		Bruilov	
Winter Palace	rebuilt 1838	Bruilov and Stasov	
Observatory	1837	Bruilov	
Triumphal Arch		Quarenghi and Starov	
Duke of Leuchtenberg's palace	1839	Stackelschneider	Grecian style.

PETERSFIELD, a market-town, parish, and parliamentary borough in the hundred of Finch-Dean, and in the present northern, but in the old southern division of Hampshire. The town, which is on the road from London to Portsmouth, is 52 miles south-west from London, and 16 miles east by south from Winchester, direct distances. It is a clean country town, partly lighted with gas, tolerably paved, and amply supplied with water. The trade is unimportant, but fairs for sheep and horses are held March 5, July 10, and December 11. The market-day is Saturday. The assessed taxes levied in 1830 amounted to 540*l.* The population of the town and parish in 1831 was 1803. The living, attached to the chapelry of Petersfield, is a curacy, which, with the rectory of Buriton, are in the diocese of Winchester and patronage of the bishop of that see, and yield an average net income of 1194*l.* Near the chapel is an equestrian statue of William III. There is a school called Churcher's college, from the name of the founder, who, in 1722, bequeathed the sum of 3000*l.* Bank stock and 500*l.* in cash for its establishment and support. The boys, from ten to twelve in number, are clothed, fed, and instructed in writing, arithmetic, and so much of the mathematics as is applicable to navigation. Several acts of parliament have been obtained for regulating the expenditure of the funds of the charity, which have increased considerably.

According to the Corporation Reports, no royal charter of incorporation is known to have been conferred upon the town; but in Warner's 'History of Hampshire,' and in other works, it is stated to have been incorporated by a charter of Queen Elizabeth, which is also confirmed by the Report of the Commissioners on the boundary of the borough. The town is governed by a mayor, chosen annually at the court-leet of the lord of the manor, but the functions of the mayor are merely nominal. The borough of Petersfield returned members to parliament as early as Edward I., and two members continuously from the reign of Edward VI. till the passing of the Reform Act, since which it has been represented by one member. The present parliamentary boundary includes the old borough of Petersfield and the tithing of Sheet; the parishes of Buriton, Lyss, and Froxfield; the tithings of Ramsden, Langrish, and Oxenbourn, in the parish of East Meon, and also the parish of Steep, except the tithings of North and South Ambersham.

(*Sixteenth Report of the Commissioners on Charities*, p. 296; *Reform Act and other Parliamentary Papers;* Warner's *Hist. of Hampshire*, &c.)

PETERWARDEIN, or **PETERVARA**, the principal and frontier fortress of Slavonia, the Gibraltar of Hungary, is situated in 45° 15′ N. lat. and 19° 55′ E. long., in the neighbourhood of some mountains and fruitful hills, on the right bank of the Danube, near the angle formed by the sudden change in the course of that river from due south to east. On a rock isolated on three sides stands the upper fortress and the hornwork; on the northern foot of the rock lies the lower fortress, which includes what is properly the town, and is partly on a gentle slope. It commands the Danube, whose waters bathe the walls on the west and south sides. It is a place of extraordinary strength both by nature and art. As a precaution in case of a very close siege, a well has been excavated in the rock to a depth below the surface of the Danube. The lower fortress has very broad and deep moats, which may be filled with water from the Danube, lofty walls, and many bastions and ravelins, by which it is separated on the south side from the two suburbs Ludwigsthal and Rochusthal. One principal street, and two others parallel to it, with a pretty extensive parade, form the whole town, which consists of only fourteen public buildings and forty-eight houses, most of the latter being only one story high. The principal buildings are the arsenal, the residence of the commandant, and the Roman Catholic parish church, formerly belonging to the Jesuits. Besides the two above-mentioned suburbs, some writers reckon the village of Bukowitz, about a league distant, as belonging to Peterwardein. The population of the town, the two suburbs, and Bukowitz, including the garrison, is stated at 6500. The fortress is capable of containing a garrison of 10,000 men.

Peterwardein is connected, by a bridge of boats over the Danube (here 700 feet wide, and from 50 to 60 feet deep), with the town of Neusatz, on the opposite bank.

(Von Jenny, *Handbuch für Reisende in dem Oesterreichischen Kaiserstaate;* W. Blumenbach, *Neuestes Gemälde der Oesterreichischen Monarchie.*)

PETIOLE is that part of the leaf commonly called the stalk; it is usually a contracted part of the leaf through which the wood-veins pass from the trunk, but in other cases it is thin, expanded flat, or rolled up in a sheathing manner, when it is scarcely to be distinguished from the blade of the leaf itself. It is the opinion of some botanists that the leaves of endogens, in which the veins are parallel instead of being reticulated, consist exclusively of petiole; but this seems contradicted by grasses which have both a petiole and lamina, with parallel veins.

PETIS DE LA CROIX, FRANÇOIS, a learned French Orientalist, born at Paris, towards the close of 1653, was the son of the king's interpreter for the Oriental languages, and received an education to qualify him for the same employment. At the early age of sixteen he was sent, by the minister Colbert, to reside in the East. He spent several years at Aleppo, Ispahan, and Constantinople, where he became master of the Arabic, Persian, and Turkish languages. During his stay at the first-named city he translated into elegant Arabic an account of the campaign of Louis XIV. in Holland, which his contemporary Pellisson published in 1671. He returned to Paris in 1680, and two years afterwards was sent to Marocco, as secretary to M. de Saint Amand, who had been appointed ambassador to Muley Ismail, the reigning sultan. He is reported to have pronounced before that sovereign a speech in Arabic which excited the admiration of the whole court by the facility of the delivery and the elegance and purity of the style. In the two following years he accompanied the French armaments against Algiers, under Duquesne, Tourville, and D'Amfreville [Algiers], filling under each of these generals the situation of secretary-interpreter of the marine, in which capacity he was employed to translate into Turkish the treaty of peace, concluded in 1684, between France and the regency of Algiers. In 1685 he performed the same office with respect to the negotiations with Tunis and Tripoli, when he gave decisive proofs of his integrity and patriotism. It is asserted that while the negotiations with the latter power were going on (one of the conditions of the treaty being that the bey of Tripoli should pay to the king of France the sum of 600,000 livres) Petis was offered a considerable bribe if he would put down in the original treaty Tripoli crowns instead of French ones, which would have made a difference of a sixth part, but his fidelity to his sovereign was incorruptible. In 1687 he assisted the Duke de Mortemart in concluding a treaty of peace and commerce with the empire of Marocco. In short, it was through his intervention that all the affairs between France and the Eastern courts were transacted from the year 1680, when he was first employed in diplomacy, to the time of his death. As a reward for his eminent services, Petis was appointed, in 1692, Arabic professor to the Collège Royal de France, and after the death of his father (1695) the office of Oriental interpreter was also conferred upon him. From this period Petis never left his native country, but employed himself in various translations from the Eastern languages, with most of which he was perfectly well acquainted; for, besides the Arabic, Turkish, and Persian, he is said to have been well acquainted with the Mogul, Armenian, and Ethiopian.

He died at Paris, December 4, 1713, at the age of sixty, leaving a son, named Alexandre Louis Marie, who succeeded him in his office of secretary-interpreter of the marine, and made likewise several translations from the Persian and the Turkish.

His principal publications are, 'Les Mille et un Jours' (the thousand and one days), translated from the Persian, Paris, 1710-12, 5 vols. 12mo.; 'Contes Turcs,' a translation from Sheikh Zadeh, Paris, 1707, 12mo.; 'The History of Timur,' translated from the Persian of Sheref-ed-din Ali Yesdi, Paris, 1722, 4 vols. 12mo. Most of his works however still remain in manuscript; these are his 'Travels through Syria and Persia, from 1670 to 1680;' a 'History of the Conquest of Syria by the Arabs,' translated from the Arabic of Wakedi; 'The Bibliographical Dictionary of Haji Khalfah,' from the Turkish; a 'History of the Ottoman Empire,' from the same language; a 'Dictionary of the Armenian Language;' a work on 'The Antiquities and Monuments of Egypt;' an 'Account of Ethiopia;' a treatise entitled 'Jerusalem, Modern and Antient;' and several others, the titles of which are given at full length in the 'Mémoire sur le Collège Royal,' by Goujet, Paris, 1758. In some biographies of Petis de la Croix, a 'History of Gengis-Khan,' from the Persian (Paris, 1710), is attributed to him; but this is an error, since the above translation, though edited by Petis, was the work of his father, whose Christian name was also François.

(Goujet, *Mémoire Historique et Littéraire sur le Collège Royal de France*, Paris, 1758, 4to.; *Biographie Universelle*, vol. xxxiii.)

PETIT, JEAN LOUIS, was born at Paris in 1674. Littre, a celebrated professor of anatomy, being a resident in his father's house, inspired the young Petit with such a zeal for the same study, that at twelve years of age he acquired sufficient dexterity in dissecting to be appointed to prepare the subjects for his preceptor's lectures, and to be placed at the head of his anatomical class. At sixteen he was apprenticed to a surgeon; and so great was his zeal in his studies, that Mareschal, the chief surgeon of the Hospital La Charité, on going very early in the morning to visit his patients, more than once found Petit asleep by the door, awaiting his arrival, that he might secure a good place during the operations. In 1692 he obtained the post of surgeon in the army, and was in active service till 1700, when he returned to Paris and obtained the degree of Master in Surgery. Here he delivered several courses of lectures to a school of anatomy and surgery which he established, and in which many of those who were afterwards among the first surgeons in Europe were pupils. His reputation rapidly increased, and he was elected a member of the Academy of Sciences at Paris, of the Royal Society of

London, and of many learned societies. In 1731, at the foundation of the Academy of Surgery in Paris, of which he was one of the most active promoters, he was elected director. He died in 1760.

Petit was for many years the most renowned surgeon in Europe, and contributed more to its advancement as a science than any one who had preceded him. He not only raised the character of surgery in France, but many of his pupils were invited to take charge of important offices in different parts of Europe, and by carrying thither his improvements and some of his zeal, gave a fresh stimulus to its progress.

At the time of his death, Petit had been engaged twelve years in the composition of an extended 'Treatise on Surgery.' It was completed and published in 1774, by De Lesne, and is still a standard work. The other most important of his surgical writings are a 'Treatise on the Diseases of the Bones,' and numerous papers published in the Memoirs of the Academies of Surgery and of the Sciences.

PETIT, PETER, was born 31st December, 1598 (Niceron), or 8th December, 1594 (*Biog. Univers.*), at Montluçon, a small town in the present department of the Allier. When young, he occupied himself in mathematical studies and experimental philosophy, which he afterwards evinced considerable aptitude in applying. In 1626 he succeeded his father in the office of 'Controlleur en l'Election de Montluçon,' which office he sold in 1633, after the death of his parents, and then removed to Paris. Here he was introduced to the Cardinal de Richelieu, and appointed by that minister to inspect the seaports of France and Italy. Between this time and 1649 there were conferred upon him the appointments of provincial commissary of artillery, intendant of fortifications, and geographer, engineer, and councillor to Louis XIII. Upon his return from Italy, he communicated to Mersenne a critical examination of the 'Dioptrics' of Descartes, which led to his being introduced to Fermat, who had also questioned the soundness of the Cartesian theory. Subsequently however he became very intimate with Descartes and an unreserved supporter of all his doctrines. In 1646-7, a series of experiments made by Pascal and Petit confirmed the explanation then recently given by Torricelli of the phenomena of the barometer and common pump. Petit died 20th August, 1667, at Lagni on the Marne, about five leagues from Paris.

The following list of his works is given by Niceron, in the forty-second volume of the 'Mémoires des Hommes Illustres:'—1, 'L'Usage du Compas de Proportion,' Paris, 1634, 8vo.; 2, 'Discours Chronologiques,' Paris, 1636, 4to.; 3, 'Carte du Gouvernement de la Capelle;' 4, 'Avis sur la Conjonction proposée des Mers Océane et Méditerranée par les Rivières d'Aude et de Garonne,' 4to.; 5, 'Observations touchant le Vide fait pour la première fois en France,' Paris, 1647, 4to.; 6, 'Discours touchant les Remèdes qu'on peut apporter aux Inundations de la Rivière de Seine dans Paris,' 1658, 4to.; 7, 'Observationes aliquot Eclipsium—Dissertatio de Latitudine Lutetiæ et Magnetis Declinatione—Novi Systematis Confutatio,' published in Duhamel's 'Astronomy,' Paris, 1659-60—(the object of the second of these tracts is to prove that the latitude of Paris was not permanent, an opinion which had been entertained with regard to geographical positions generally by the Italian astronomer Maria); 8, 'Dissertation sur la Nature des Comêtes,' Paris, 1665, 4to. (written at the desire of Louis XIV., to lessen the alarms of the people occasioned by the appearance of the comet of 1664); 9, 'Lettre touchant le Jour auquel on doit célébrer la Fête de Pâques,' Paris, 1666, 4to.; 10, 'Dissertations sur la Nature du Chaud et du Froid,' Paris, 1671, 12mo.

(Montucla, *Histoire des Mathématiques*; Niceron.)

PETITION. A petition is an application in writing, addressed to the lord chancellor, the master of the rolls, or to the Equity side of the Court of Exchequer, in which the petitioner states certain facts as the ground on which he prays for the order and direction of the court. Petitions are either *cause* petitions or not. A cause petition is a petition in a matter of which the court has already possession by virtue of there being a suit concerning the matter of the petition; and the petitioner is generally either a party to such suit, or he derives a title to some interest in the subject matter of the suit from a party to it. When there is no suit existing about the matter of the petition, it is called an *ex parte* petition.

Some cause petitions are called petitions of course, and relate to matters in the ordinary prosecution of a suit, and before a decree. Such petitions are granted upon application of the party petitioning; and they may be presented at any time, whether the courts are sitting or not. They are not answered when presented, in the same manner that other petitions are; but the order to be made on such petition (if presented at the Rolls) is at once drawn up by the secretary of the master of the Rolls, unless they are petitions for rehearing. Such petitions may also be presented to the lord chancellor.

Other petitions in a cause, which are not petitions of course, and may be called special petitions, have for their object to carry a decree into execution. Thus a party who has an interest in a fund in court, a legatee for instance who was a minor when the decree was made, may, when he is of age, apply by petition to have his share paid to him, because his right to it has been recognised by a decree or order of the court, or by a master's report which has been confirmed. The nature of the petitions in a cause will of course vary with the subject-matter of the suit.

Petitions, not in a cause, are of various kinds, and many of them are presented under the authority of particular acts of parliament. These also are called special petitions. Thus a petition may be presented for the appointment of guardians to infants, and for an allowance for their maintenance; for the purpose of procuring an order of court that infant trustees and mortgagees may execute conveyances; and for various other purposes. In matters of lunacy, the form of proceeding in the first instance is by petition to the chancellor, to whom the care of lunatics and idiots is specially delegated by the crown, and the prayer of the petition is for a commission to inquire into the state of mind of the alleged lunatic. [LUNACY.] In subsequent proceedings relating to the property of a person, when found lunatic by a jury, a petition is the regular and usual course of proceeding; and suits are not commenced or defended for the lunatic without the previous approval and direction of the court.

All special petitions must be presented to the court to which they are addressed, in order to be answered: until they are answered, the court is not fully possessed of the matter of the petition. The answer, which is written on the copy of the petition and signed by the judge, requires the attendance before him of all parties concerned in the matter of the petition at the hearing thereof. It is the business of the petitioning party to serve all proper parties with notice of this petition, and the answer to the petition becomes an order of the court, upon every person whom the petitioner chooses to serve with the petition, to attend at the hearing of it; and if such person be absent at the hearing, he will be bound by the order made on the petition. Service of the petition consists in delivering a true copy of the petition as answered to the clerk in court whose attendance the petitioner thinks necessary, or to the party himself. In some special cases, the petitioner is permitted, on special motion, supported by an affidavit that he is unable to serve the party personally, to leave the copy of the petition at the party's house with one of his family, and this will be considered good service. Special petitions frequently require to be supported by affidavits of the petitioner or some other person, or of both; and such affidavits may be filed at any time after the petition is answered. If a petitioner choose to serve a party with a petition, whose presence is considered by the court to be unnecessary, he must pay such party the cost of attending at the hearing of the petition.

A petition is heard in court by the counsel for the petitioner stating the substance and prayer of the petition, and by reading or briefly stating the contents of the affidavits filed in support of the petition, if any have been filed. If the prayer of the petition is opposed by any of the parties who have been served with it, they are heard by their counsel, and their affidavits also, if any have been filed, are read or briefly stated to the court. On hearing the matter of the petition and the affidavits on both sides, the court either dismisses the petition or makes such order as it thinks fit. The order when made is drawn up, passed, entered, served, and enforced like any other decree or order of the court. Before any order made on a petition can be passed, the original petition must be filed with the clerk of reports. The order itself in the present practice recites no part of the petition except the prayer.

PETITION OF RIGHT. Where the crown or a subject has a cause of action against a subject, the ordinary mode of putting that cause of action into a course of legal investigation is by the king's writ, requiring the party to appear in court to answer the complaint. Where the claim is against the crown itself, as this course cannot be pursued, the mode of proceeding provided by common law is to present a petition to the crown, praying for an inquiry and for the remedy to which the party conceives himself to be entitled. As by Magna Charta the king is not to delay right, he is bound, if the petition presents that which has the semblance of a legal or equitable claim, to indorse the petition with the words 'let right be done;' which indorsement operates, in the case of a claim of a legal nature, as a warrant and command to the lord chancellor to issue a commission to inquire into the truth of the matters alleged in the petition. A commission accordingly issues to six or eight persons, who summon a jury, of whom not less than twelve or more than twenty-three are impannelled, and who, under the superintendence of the commissioners, hear the evidence which the petitioner, or, as he is called, the suppliant, has to adduce in support of his statement. If the jury negative the allegations contained in the petition, the commission is at an end; but the suppliant is at liberty to sue out a new commission or commissions till a jury return an inquisition in which the allegations are found to be true. The crown may, upon this return, insist that the facts alleged by the suppliant, and found by the inquisition, do not in point of law entitle the suppliant to the remedy which he claims. The question of law thus raised by demurrer to the inquisition is argued before the lord chancellor. The crown however, notwithstanding the finding of the jury, may deny the truth of the facts, or, admitting them to be true, may allege other facts which show that the suppliant is not entitled to what he claims. To such facts the suppliant must reply. Any issue of fact joined between the suppliant and the crown is tried in the court of King's Bench, the lord chancellor not having the power to summon a jury. Final judgment is given for or against the suppliant according to the result of the argument upon the demurrer or of the trial of the issue.

If the suppliant in his petition pray that the investigation may take place in a particular court, and the royal indorsement on the petition directs that course to be pursued, the proceedings take place in the court indicated by the indorsement, instead of the Court of Chancery.

Before the abolition of the feudal tenures by the Commonwealth (confirmed after the Restoration, by 12 Car. II., c. 24), the rights of the crown and of the subject being often brought into collision, occasions for proceeding by petition of right were very frequent, and as this mode of proceeding was dilatory and expensive, two acts, passed in the reign of Edward III., enabled parties aggrieved in certain cases by legal proceedings of the crown, to enter their claim upon those proceedings, without being put to their petition of right, with its expensive commission to inquire. This new course was called a 'traverse of office,' where the subject denies the matters contained in the 'office' or *ex parte* record constituting the king's title, and a 'monstraunce de droit,' where the facts upon which the king's title rests are admitted but their effect is avoided by the allegation of other facts showing a better title in the claimant. In modern practice the petition of right is not resorted to, except in cases to which neither a traverse of office nor a monstraunce de droit applies, or after those remedies have failed.

The petition of right is supposed by Lord Coke and others to be so called because the investigation prayed for is demandable as of right, and not granted as a matter of grace or favour; but the Latin term 'petitio justitiæ' shows that the words are used in the sense of a 'petition *for right*.'

PETITION OF RIGHT. In the first parliament of Charles I., which met in 1626, the Commons refused to grant supplies until certain rights and privileges of the subject, which they alleged had been violated, should have been solemnly recognised by a legislative enactment. With this view they framed a petition to the king, in which, after reciting various statutes by which their rights and privileges were recognised, they pray the king 'that no man be compelled to make or yield any gift, loan, benevolence, tax, or such-like charge, without common consent by act of parliament,—that none be called upon to make answer for refusal so to do,—that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge,—that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm,—that commissions for proceeding by martial law be revoked: all which they pray as their rights and liberties according to the laws and statutes of the realm.'

To this petition the king at first sent an evasive answer: 'The king willeth that right be done according to the laws and customs of the realm, and that the statutes be put in due execution, that his subjects may have no cause to complain of any wrongs or oppressions contrary to their just rights and liberties, to the preservation whereof he holds himself in conscience obliged as of his own prerogative.' This answer being rejected as unsatisfactory, the king at last pronounced the formal words of unqualified assent, 'Let right be done as it is desired.' (1 Car. I., c. 1.) Notwithstanding this however the ministers of the crown caused the petition to be printed and circulated with the first insufficient answer.

PETITOT, JOHN, an eminent painter in enamel, the son of a sculptor and architect, was born at Geneva, in 1607. Being designed for the trade of a jeweller, he was placed under the direction of Bordier, and in this occupation was engaged in the preparation of enamels for the jewellery business. He was so successful in the production of colours, that he was advised by Bordier to attempt portraits. They conjointly made several trials, and though they still wanted many colours which they knew not how to prepare for the fire, their attempts had great success. After some time they went to Italy, where they consulted the most eminent chemists, and made considerable progress in their art, but it was in England, whither they removed after a few years, that they perfected it.

In London they became acquainted with Sir Theodore Mayern, first physician to Charles I., and an intelligent chemist, who had by his experiments discovered the principal colours proper to be used in enamel, and the means of vitrifying them, so that they surpassed the boasted enamelling of Venice and Limoges. Petitot was introduced by Mayern to the king, who retained him in his service and gave him apartments in Whitehall. He painted the portraits of Charles and the royal family several times, and copied many pictures, after Vandyck, which are considered his finest works. That painter greatly assisted him by his advice, and the king frequently went to see him paint.

On the death of Charles, Petitot retired to France with the exiled family. He was greatly noticed by Charles II., who introduced him to Louis XIV. Louis appointed him his painter in enamel, and granted him a pension and apartments in the Louvre. He painted the French king many times, and, amongst a vast number of portraits, those of the queens Anne of Austria and Maria Theresa. He also occupied himself in making copies from the most celebrated pictures of Mignard and Lebrun.

Petitot, who was a zealous Protestant, dreading the effects of the revocation of the Edict of Nantes, solicited leave, but for a long while in vain, to return to Geneva. The king employed Bossuet to endeavour to convert him to Romanism, in which however that eloquent prelate was wholly unsuccessful. At length Louis permitted him to depart, and leaving his wife and children in Paris, he proceeded to his native place, where he was soon after joined by his family. Arrived now at eighty years of age, he was sought by such numbers of friends and admirers, that he was forced to remove from Geneva and retire to Vevay, a small town in the canton of Berne, where he continued to labour until 1691, in which year, whilst painting a portrait of his wife, he was suddenly attacked by apoplexy, of which he died.

Bordier, in conjunction with whom he worked for fifty years, and who painted the hair, backgrounds, and draperies of his pictures, married his wife's sister. In the museum of the Louvre there is a collection of fifty-six portraits by Petitot; but his principal work is a magnificent whole-length portrait of Rachel de Rouvigny, countess of Southampton, in the collection of the duke of Devonshire, painted from the original in oil by Vandyck, in the possession of the earl of Hardwicke. This enamel is nine inches and three-quarters high, by five inches and three-quarters wide, a prodigious size for a work of this description, and by far the largest that had been then, and for a century and a half afterwards, executed. It is dated 1642. This work was some years ago entrusted to the late Mr. Bone, the enamel painter and royal academician, to repair, it having been seriously damaged by a fall, by which a large portion of the enamel had been displaced. Different from the practice now adopted, the plate on which this was painted is formed upon a very thick piece of gold, the back having cross-bars attached of the same metal, filled up with enamel, the metal alone weighing more than three ounces.

In the earlier part of his career Petitot received twenty guineas for a portrait, which price he afterwards raised to forty. He generally used plates of gold, but seldom copper, and sometimes, it is said, silver, though this seems improbable, for that metal generally has the effect of tinging the enamel with yellow. Amongst a vast number of his works painted in England, we have never met with one the plate of which was composed of silver. His custom was to have a painter to draw the likeness of his sitter in oil, from which he commenced his enamel, and then finished it from life. He copied those of Louis XIV. from the best portraits of him, but generally obtained one or two sittings for the completion.

The pictures which Petitot painted in England are executed in a more free style, and have a greater depth and richness of tint than those executed in France, whilst the latter are remarkable for the extreme delicacy of touch and the exquisitely elaborate finish. He may be called the inventor of enamel painting, for though subjects of fruit and flowers were long before painted on this material for the purposes of jewellery, he was the first who made the attempt to execute pictures, and it was he who at once brought the art to perfection. The principal objection to the tone of colour of his works, a defect observable in the pictures of all other practitioners in enamel till the present century, is a prevalence of purple in the flesh tints.

He had a son, John, who followed this art in England, but his pictures, though possessing great merit, are inferior to those of the father. (Walpole's *Anecdotes of Painting*, by Dallaway; *Biographie Universelle*.)

PETRA (Πέτρα, or αἱ Πέτραι), which lay nearly half way between the Dead Sea and the head of the Ælanitic Gulf, was one of the most important towns in the north of Arabia, and the capital of the Nabathæi. It is in all probability the Sela (סֶלַע) of the Old Testament, which signifies, like the Greek word, a 'rock.' This town, which originally belonged to the Edomites, was taken by Amaziah, king of Judah, who changed its name into that of Joktheel (2 *Kings*, xiv. 7; compare Joseph., *Antiq.*, ix. 9, § 1); but it seems in later times to have belonged to the Moabites. (*Is.*, xvi. 1.)

Petra is described by Strabo (xvi., p. 779) and Pliny (*Hist. Nat.*, vi. 32) as situated on level ground about two miles in size,* and surrounded by precipitous mountains. The town itself was well watered, but the surrounding country, and especially the part towards Judæa, was a complete desert. It was 600 Roman miles from Gaza, and three or four days' journey from Jericho. In the time of Augustus, Petra was a large and important town, and its greatness appears to have been principally owing to its situation, which caused it to be a great halting-place for caravans. A friend of Strabo's, of the name of Athenodorus, who had resided at Petra for many years, informed the geographer that many Romans lived there, as well as other foreigners. (Strabo, xvi., p. 779.) It maintained its independence against the attempts of the Greek kings of Syria (Diod. Sic., xix. 95-97), and was governed by a native prince in the time of Strabo. It was taken by Trajan (Dion Cass., lxviii. 14); and it appears from coins (Eckhel, *Doctr. Num.*, ii. 503) that Hadrian called it after his own name (Ἀδριάνη).

The ruins of Petra still exist in the Wady Musa, two days' journey from the Dead Sea, and the same distance northeast of Akaba. They were visited by Burckhardt in the year 1812, by Captains Irby and Mangles in 1818, and more recently by Laborde. Burckhardt's visit was brief and hasty, but a minute description of the ruins has been given by Captains Irby and Mangles, from whose account we extract the following remarks. The principal entrance to the town appears to have been through a narrow valley formed by the passage of a small rivulet through the rocks, which in some places approach so near to one another as only to leave sufficient room for the passage of two horsemen abreast. This narrow valley extends for nearly two miles; and on each side of it there are numerous tombs cut out of the rocks, which, as you approach nearer the city, become more frequent on both sides, till at length nothing is seen but a continued street of tombs. Nearly at the termination of this valley there are the ruins of a magnificent temple, entirely cut out of the rock, 'the minutest embellishments of which, wherever the hand of man has not purposely effaced them, are so perfect that it may be doubted whether any work of the antients, excepting perhaps some on the banks of the Nile, have come down to our time so little injured by the lapse of age. There is in fact scarcely a building of forty years' standing in England so well preserved in the greater part of its architectural decorations.'

After passing this temple, the valley conducts to the theatre, 'and here the ruins of the city burst on the view in their full grandeur, shut in on their opposite sides by barren craggy precipices, from which numerous ravines and valleys, like those we had passed, branch out in all directions. The sides of the mountains, covered with an endless variety of excavated tombs and private dwellings, presented altogether the most singular scene we have ever beheld, and we must despair of giving the reader an idea of the singular effect of rocks tinted with the most extraordinary hues, whose summits present to us nature in her most savage and romantic form, while their bases are worked out in all the symmetry and regularity of art, with colonnade and pediments, and ranges of corridors adhering to the perpendicular surface.'

The best description of the ruins of Petra is given in Laborde's 'Voyage de l'Arabie Petrée,' Par., 1830, of which an English translation was published in 1836.

PETRARCA, FRANCESCO, born at Arezzo, in July, 1304, was the son of Pietro, or Petracco (an idiomatic form of Pietro), a notary of Florence, who was banished in 1302, at the same time as Dante and others of the Bianchi faction. [DANTE.] The true name of Petrarca was Francesco di Petracco, or 'Francis the son of Petracco,' which he afterwards changed into the more euphonic name of Francesco Petrarca. After losing all hope of being restored to his native town, Petracco removed with his family to Avignon, where Pope Clement V. had fixed the residence of the Papal court, and whither strangers from every country resorted. His son Francesco, after studying grammar and rhetoric, was sent by his father to Montpellier, and afterwards to Bologna to study law, which was considered the most profitable profession. Young Petrarca however had little taste for the law, especially as it was taught in that age, and he devoted much of his time to reading and copying MSS. of the classic writers. His father and mother having died at Avignon nearly about the same time, Petrarca left Bologna, and on his arrival at Avignon he found that his paternal inheritance was but little. He assumed the clerical dress, without however having taken priestly orders, that habit being then, as it still is, the customary dress of good company at the Papal residence. The Papal court of Avignon was very gay and even licentious; and Petrarca, who was then only two and twenty years of age, and of a handsome person, was one of the gayest in the fashionable circles. But his love of pleasure was tempered by the love of study. He contracted a friendship with the jurist Soranzo, with the canon John of Florence, who was apostolic secretary, and with James Colonna, bishop of Lombes in Gascony, and other distinguished men, who were fond of learning, and who supplied him with books, a scarce and expensive commodity in those times. Petrarca accompanied the bishop of Lombes to his diocese at the foot of the Pyrenees, where they spent much of their time in literary discussions and excursions in the mountains, with two other friends of similar tastes, whom Petrarca has recorded under the classical names of Socrates and Laelius (*Trionfo d'Amore*, ch. 4). On his return to Avignon, the Cardinal John Colonna, brother of James, gave Petrarca apartments in his own palace, and became his patron; and when his father, Stephen Colonna, a sturdy warlike old baron, but not illiterate, and well known for his quarrels with Boniface VIII., came from Rome to Avignon on a visit to his sons, Petrarca was introduced to him, and soon won his favour. Petrarca, who was an admirer of the heroes of antient Rome, fancied that he saw in Stephen Colonna their worthy descendant, and in several of his verses, addressed to him, he calls him 'the hope of the Latin name' (*Sonetto* 10). Azzo da Correggio, lord of Parma, having come to Avignon to defend, before Pope Benedict XII., his title to that sovereignty against the claims of Marsiglio Rossi, became acquainted with Petrarca, and prevailed on him to act as his advocate at the Papal chancery. Petrarca undertook the cause and won it. Azzo had brought with him Guglielmo Pastrengo, a learned man of Verona, the author of a work 'De Originibus Rerum,' a kind of historical dictionary in alphabetical order, which is considered the first specimen of that kind of work. Petrarca formed an intimacy with Pastrengo as well as with the Calabrian monk Barlaam, who came to Avignon on a mission from the emperor Andronicus the younger, and from whom he learned the rudiments of Greek. But before this time an incident had occurred which exercised a powerful influence over Petrarca's life.

---

* Pliny probably means circumference; he merely says 'amplitudinis.'

On the 6th of April, 1327, while he was attending service in the church of St. Clair, at Avignon, he was struck with the beauty of a young lady who happened to be near him, and he conceived a violent passion for her. The lady's name was Laura. According to the received opinion, supported by documents, for Petrarca himself never mentions her family name, she was the daughter of Audibert of Noves, a small place in the territory of Avignon; she had a considerable fortune, and had been married about two years to Hugh de Sade, a gentleman of Avignon: when Petrarca first saw her, she was nineteen years of age. The attractions of Laura's person have been so fully described and probably exaggerated by Petrarca, that it is needless to say anything on the subject. But the qualities of her mind, which he also praises, seem to have been truly remarkable in a provincial lady of those times and of no very exalted rank. In her conduct for a long course of years towards her handsome, accomplished, and impetuous admirer, whom she could not help meeting wherever she went, at parties of pleasure, in walking, or at church, she exhibited a rare mixture of firmness and courtesy, of respect for her own character with a considerate regard for her enthusiastic lover. She has been called a coquette, but we ought not to judge the conduct of a Frenchwoman of the fourteenth century by the standard of manners in England or even France in the nineteenth century. To those acquainted with the manners of Italy and Spain even at the present day, the passion of Petrarca for Laura de Sade is nothing uncommon. Such attachments are frequent, and though often of a platonic nature, are certainly not always so. That the attachment of Petrarca continued to be platonic, was owing to Laura's sense of duty, or to her indifference, or to both, but that it did not drive her lover to madness and ruin was owing to her consummate address, of which we hav[illegible]abundant evidence in Petrarca's own confessions. When he ventured on a declaration, she sternly rebuked him, and avoided his presence; but when she heard that he was ill, she assumed towards him the manners of a friend interested in his welfare; she succeeded in purifying his passion, and in making him satisfied with her conversation, and with giving vent to his feelings in poetry. (Petrarca's Latin *Epistle to James Colonna, bishop of Lombes.*) She was probably flattered by his praise, which brought no imputation on her character, and made her the most celebrated woman of her day. Petrarca's sonnets and canzoni in praise of Laura circulated throughout Europe. When Charles of Luxemburg, afterwards the emperor Charles IV., came on a visit to Avignon, one of his first inquiries was after the Laura celebrated by Petrarca, and being introduced to her in the midst of a large assembly, he respectfully begged to be allowed to kiss her on the forehead as a mark of his esteem. (Petrarca, *Sonnet* 201.) It was not however without a violent struggle that Petrarca allowed himself to be led by her better judgment. For ten years after he had first seen Laura, his life was one continued strife between his passion and his reason. He left Avignon repeatedly, travelled about, returned, but was still the same. Wishing, if possible, to forget Laura, he formed a connection with another woman, and had by her a son, and afterwards a daughter. But still his mind recurred perpetually to the object of his first attachment. He took care of his illegitimate children, but broke off the connection. For several years he fixed his residence at Vaucluse, a solitary romantic valley near Avignon, on the banks of the Sorga, of which he has given some beautiful descriptions. In a letter addressed to James Colonna, and dated June, 1338, he assigns as a reason for his retirement, that he was disgusted with the vice and dissoluteness of the Papal court of Avignon, in leaving which, he says, he sang to himself the psalm 'In exitu Israel de Ægypto.' He also says, that he was tired of waiting for the fulfilment of the promises of honour and emolument made to him by the pope.

Meantime, year after year rolled on, and the beauty of Laura faded away. She became the mother of a large family. But Petrarca continued to see her with the eyes of youth, and to those who wondered how he could still admire her, he answered:

'Piaga per allentar d'arco non sana.

('The bow can no longer wound, but its mortal blow has been already inflicted. If I had loved her person only, I had changed long since.') In the year 1343, sixteen years after his first sight of Laura, he was writing in the soberness of self-examination: 'My love is vehement, excessive, but exclusive and virtuous.—No, this very disquietude, these suspicions, this watchfulness, this delirium, this weariness of every thing, are not the signs of a virtuous love.' (*De Secreto Conflictu.*)

In the year 1348, while Petrarca was staying in Italy, the plague spread into France and reached Avignon. Laura was attacked by the disease, and she died after three days' illness, on the 6th of April, in the fortieth year of her age. Her death, from the account of witnesses, appears to have been placid and resigned as her life had been. Petrarca has beautifully described her passing away like a lamp which becomes gradually extinct for want of nourishment:

'A guisa d'un soave e chiaro lume
  Cui nutrimento a poco a poco manca.
Pallida nò, ma più che neve bianca,
  Che senza vento in un bel colle fiocchi,
  Parea posar come persona stanca.'
(*Trionfo della Morte*, ch. i.)

When the news reached Petrarca in Italy, he felt the blow as if he had lost the only object that attached him to earth. He wrote on a copy of Virgil, his favourite author, the following memorandum: 'It was in the early days of my youth, on the 6th of April, in the morning, and in the year 1327, that Laura, distinguished by her virtues, and celebrated in my verses, first blessed my eyes in the church of St. Clara, at Avignon; and it was in the same city, on the 6th of the very same month of April, at the same hour in the morning, in the year 1348, that this bright luminary was withdrawn from our sight, whilst I was at Verona, alas! ignorant of my calamity. The remains of her chaste and beautiful body were deposited in the church of the Cordeliers, on the evening of the same day. To preserve the painful remembrance, I have taken a bitter pleasure in recording it particularly in this book, which is most frequently before my eyes, in order that nothing in this world may have any further attraction for me, and that this great bond of attachment to life being now dissolved, I may by frequent reflection, and a proper estimation of our transitory existence, be admonished that it is high time for me to think of quitting this earthly Babylon, which I trust will not be difficult for me, with a strong and manly courage, to accomplish.' Petrarca's 'Virgil,' with this affecting memorandum, is now in the Ambrosian library at Milan. (Valéry, *Voyages Littéraires.*)

Here begins a new period of the life of Petrarca, and with it the second part of his love poetry. Hitherto he had written verses in praise of Laura; he now wrote verses 'on Laura's death.' He fancied himself in frequent communion with her spirit; he describes her appearing to him in the middle of the night, comforting him, and pointing to Heaven as the place of their next meeting. (Sonnet beginning *Levommi il mio pensier*, and the other *Nè mai pietosa madre.*) This delusion, if delusion it be, is the last remaining consolation of impassioned minds which have lost all that they valued in this world; and it has at least one beneficial effect, that of rendering life bearable and preventing despair. The second part of Petrarca's poetry is superior to the first in purity of feeling and loftiness of thought. He himself felt this, and blessed the memory of her who, by the even tenour of her virtue, had been the means of calming and purifying his heart.

'Benedetta colei che à miglior riva
Volse il mio corso, e l'empia voglia ardente
Lusingando affrenò perch'io non pera.' (*Sonnet* 249.)

More than twenty years after Laura's death, when he was himself fast verging towards the grave, and when he was able to think of her with more composure, he drew from his memory a picture of the heart, the principles, and the conduct of the woman who had made all the happiness and all the misery of his life. He describes Laura as appearing to him through a mist, and reasoning with him on the happiness of death to a well prepared mind; she tells him that when she died she felt no sorrow except pity for him. On Petrarca entreating her to say whether she ever loved him, she evaded the question by saying that although she was pleased with his love, she deemed it right to temper his passion by the coldness of her looks, but that when she saw him sinking into despondency, she gave him a look of consolation and spoke kindly to him. 'It was by this alternation of kindness and rigour that I have led thee, sometimes happy, sometimes unhappy, often wearied in truth, but still I have led thee to where there is no more danger, and I have thus saved us both. There has been little difference in our sympathy, except that thou didst proclaim thine to all the world, and I concealed mine. But complaint does not embitter suffering, nor does silence soften it.'

'Non è minore il duol, perch' altri il prema;
Ne maggior per andarsi lamentando.' (*Trionfo della Morte*, ch. ii.)

We have dwelt at some length on this subject because it has acquired an historical importance, and has been the subject of much controversy. Unable to comprehend feelings with which they were unacquainted, some critics have sneered at the passion of Petrarca for Laura; others have doubted its existence; whilst others again have disbelieved the purity of Laura's conduct. We have now however sufficient evidence to establish two facts: 1, that the attachment of Petrarca for Laura was real and lasting; 2, that Laura's conduct was above suspicion. What her inward feelings were towards the poet we have no means of knowing, and Petrarca himself does not seem to have ever known. Laura appears to have been imbued with religious sentiments, united with serenity of mind, self-possession, discretion, and good sense. There have been doubts expressed concerning the identity of the Laura of Petrarca with Laura de Sade, but the evidence seems to be strong in favour of that identity. (De Sade, *Mémoires pour la Vie de F. Pétrarque;* Foscolo, *Essays on Petrarch;* Baldelli, *Del Petrarca e delle sue Opere*, 2nd edition, Fiesole, 1837; and the article 'Noves, Laure de,' in the *Biographie Universelle.*)

But the life of Petrarca was not spent in idle though eloquent wailings. He was an active labourer in the field of learning, and this constitutes his real merit and his best title to fame. Besides the works which he wrote, he encouraged literature in others, and he did everything in his power to promote sound studies. Petrarca was a great traveller for his age; he visited every part of Italy, he went several times to France and Germany, and even to Spain. Wherever he went, he collected or copied MSS., and purchased medals and other remains of antiquity. At Arezzo he discovered the 'Institutions' of Quintilian; at Verona, Cicero's Familiar letters; in another place, the epistles to Atticus; at Liège he found some orations of Cicero, which he transcribed; he also speaks of Cicero's book 'De Gloria,' of Varro's treatise 'De Rebus Divinis et Humanis,' and of a compilation of letters and epigrams of Augustus, which he had once seen or possessed, but which have not come down to us. (*Rerum Memorandarum*, b. i.) He was liberal in lending MSS., and thus several of them were lost. He applied himself also to the diplomatic history of the dark ages, and he investigated the means of distinguishing authentic diplomas and charters from numerous others which were apocryphal. (*Epistolæ Seniles*, b. xv., ep. 5.) He was the friend and instructor of Boccaccio, John of Ravenna, and other Italian and foreign contemporaries. He was the founder of the library of St. Mark at Venice. He encouraged Galeazzo Visconti to found the university of Pavia. In his extensive correspondence with the most distinguished persons of his time, he always inculcated the advantages of study, of the investigation of truth, and of a moral conduct; he always proclaimed the great superiority of intellectual over corporeal pleasures. He and his friend Boccaccio are justly considered as the revivers of classical literature in Italy. His admiration of antiquity was carried to excess, not being tempered by the light of criticism which arose much later in Europe. It was this classical enthusiasm that led him to support the tribune Rienzi, and attach too great importance to his abortive schemes. Petrarca beheld Rome as entitled to be again what she had once been, the mistress of the world, as if the thing were possible, or even desirable. This error he perpetuated by his writings, and his authority has contributed to that classical tendency of recollections and aspirations which has led astray many Italian minds. By aspiring to be what they cannot be again, they have lost sight of what they might and ought to be as members of the great modern European family.

Petrarca acted an important part in the affairs of state of his time. His influence over the great and powerful is one of the most extraordinary parts of his character, but it is a well ascertained fact. He enjoyed the friendship of several popes, of the Correggio lords of Parma, of the Colonna of Rome, the Visconti of Milan, the Carrara of Padua, the Gonzaga of Mantua, of Robert, king of Naples, and of Charles IV., emperor of Germany. He was invited in turn by them all, was consulted by them, and was employed by them in several affairs of importance. He was sent by the nobles and people of Rome as their orator to Clement VI., in order to prevail on that pope to remove his residence from Avignon to Rome. He afterwards wrote a Latin epistle to Urban V., Clement's successor, urging the same request, and the pope soon after removed to Rome, at least for a time. In 1340 the senate of Rome sent him a solemn invitation to come there and receive the laurel crown as a reward of his poetical merit. Petrarca accepted the invitation, and, embarking at Marseille, landed at Naples, where King Robert, himself a man of learning, in order to enhance his reputation, held a public examination in presence of all his court during three days, in which various subjects of science and literature were discussed. At the termination of these meetings, King Robert publicly proclaimed Petrarca to be deserving of the laurel crown, and sent an orator to accompany him to Rome to attend the ceremony, which took place on Easter-day in the year 1341, when Orso dell' Anguillara, senator of Rome, crowned the poet in the Capitol, in presence of a vast assemblage of spectators, and in the midst of loud acclamations.

Petrarca had ecclesiastical benefices at Parma and at Padua, which were given to him by his patrons of the Correggio and Carrara families, and he spent much of his time between those towns. From Padua he sometimes went to Venice, where he became acquainted with the Doge Andrea Dandolo, who was distinguished both as a statesman and as a lover of literature. Venice was then at war with Genoa. Petrarca wrote a letter to Dandolo from Padua, in March, 1351, in which he deprecated these hostilities between two Italian states, and exhorted him to peace. Dandolo, in his answer, praised his style and his good intentions; but he defended the right of Venice, after the provocations that she had received from her rival. In the following year, after a desperate battle between the fleets of the two nations in the Sea of Marmara, Petrarca wrote from Vaucluse, where he then was, to the doge of Genoa, for the same laudable purpose, that of promoting peace. In the next year, 1353, the Genoese fleet was totally defeated by the Venetians off the coast of Sardinia; and Genoa in its humiliation sought the protection of John Visconti, archbishop and lord of Milan, the most powerful Italian prince of his time. Petrarca was staying at Milan as a friend of Visconti, who had made him one of his councillors, and as such he was present at the solemn audience of the deputies of Genoa and at the act of surrender. In 1354 Visconti sent Petrarca on a mission to Venice to negotiate a peace between the two republics. He was received with great distinction, but failed in the object of his mission. Soon after, John Visconti died, and his three nephews divided his dominion amongst them. The youngest and the best of them, Galeazzo, engaged Petrarca to remain at Milan near his person. In November, 1354, the emperor Charles IV. arrived at Mantua from Germany; and he wrote to Petrarca, who had been in correspondence with him before, to invite him to his court. Petrarca repaired to Mantua, spent several days with the emperor, and accompanied him to Milan. Petrarca wished to persuade him to fix his residence in Italy; but the emperor, after being crowned at Milan and at Rome, hastened to return to Germany. However, before he left Italy, peace was proclaimed between Venice and Genoa. In 1356 Petrarca was sent by the Visconti on a mission to the emperor, whom they suspected of hostile intentions towards them. He met Charles at Prague, and having succeeded in his mission, he returned to Milan. In 1360 he was sent by Galeazzo Visconti on a mission to Paris to compliment King John on his deliverance from his captivity in England. In his 'familiar epistles' he describes the miserable state of France, and the traces of the devastation perpetrated by fire and sword. He was well received by the king and the dauphin, and after three months spent at Paris, he returned to Milan. The next year he left Milan to reside at Padua. The introduction into Italy of the mercenary bands, called 'Companies,' which the marquis of Montferrat and other Italian princes took into their pay, and which committed the greatest outrages, and the plague which they brought with them into Lombardy, were the reasons which induced Petrarca to remove to Padua. In 1362, the plague having reached Padua, he retired to Venice, taking his books with him. Soon after his arrival, he offered to bequeath his library to the church of St. Mark. The offer was accepted, and a large house was assigned for the reception of Petrarca and his books. This was the beginning of the celebrated library of St. Mark, which was afterwards increased by Cardinal Bessarion and others. At Venice, Petrarca was visited by his friend Boccaccio, who spent three months in his company. Petrarca passed several years at Venice, honoured by the doge and the principal senators, and now and then making excursions to Padua, Milan, and Pavia, to visit his friends the Carrara and Galeazzo Visconti. In 1368 he was present at the marriage of Galeazzo's daughter Violante with Prince Lionel of England. From Milan he returned to Padua, where he received a pressing invitation from Pope Urban V., who had fixed his residence at Rome, and who wished to become acquainted with him. Petrarca had a great esteem for Urban's character; and he determined, notwithstanding his age and his infirmities, on a journey to Rome; but, on arriving at Ferrara, his strength failed him; he fell into a swoon, and remained for thirty hours apparently dead. Nicholas d'Este, lord of Ferrara, and his brother Hugo, took the greatest care of him, and he was restored to life; but the physicians declared that he was unable to proceed to Rome, and he was taken back to Padua in a boat. Petrarca had been long subject to palpitations and epileptic fits, the consequence of his too great application to study. From Padua he removed, in the summer of 1370, to Arquà, a pleasant village in the Euganean Hills, where he enjoyed a pure air and retirement. He built a house there, and planted a garden and orchard: this is the only residence of the numerous houses which he had at Parma, Padua, Venice, Milan, Vaucluse, and other places, which still remains, and is shown to travellers. In this retirement he resumed his studies with fresh zeal. Among other things, he wrote his book 'De sui ipsius et multorum aliorum Ignorantia,' intended as a rebuke to certain Venetian freethinkers who, inflated with the learning which they had gathered from Averroes' 'Commentaries on Aristotle,' of which a Latin translation had spread into Italy, sneered at the Mosaic account of the creation, and at the Scriptures in general. Four of these young men had sought the society of Petrarca while he resided at Venice, and he was at first highly pleased with them; they were accomplished and witty, and fond of study. But this sympathy did not last long. Petrarca had no blind veneration for Aristotle, and still less for Averroes; he was a believer in the Scriptures, and moreover he had no great bias for natural history, in which his visitors were skilled, and he used to observe to them that it was of greater importance to 'investigate the nature of man than that of quadrupeds, birds, and fishes.' The four admirers of Aristotle were scandalised at his own freethinking concerning their oracle, and they held a kind of jury among them to decide upon the true merits of Petrarca. The verdict was, that Petrarca was a good kind of a man, but destitute of real learning, 'Bonus vir, sine literis.' This judgment spread about Venice, and made a great noise. Petrarca at first laughed at it, but his friends took up the business seriously, and urged him to defend himself, which he did in his retirement at Arquà, by the book already noticed. In this work he acknowledges his own ignorance, but at the same time he exposes the ignorance of his antagonists. With regard to Aristotle he says what others have said after him, that 'he was a great and powerful mind, who knew many things, but was ignorant of many more.' As for Averroës, who discarded all revelation, and denied the immortality or rather the individuality of the human soul, Petrarca urged his friend Father Marsili of Florence to refute his tenets. (*Epistolæ sine Titulo*, the last epistle.) But the tenets of Averroes took root at Venice and at Padua, where many professors, down to the time of Leo X., among others Urbano of Bologna, Nicola Vernia, Agostino Niso, Alessandro Achillini, Pomponacio, and others, professed them, and commented on the works of the Arabian philosopher. It has even been said that Poliziano, Bembo, and others of the distinguished men who gathered round Lorenzo de' Medici and his son Leo X. entertained similar opinions.

The air of the Euganean hills did not prove sufficient to restore Petrarca to health. His physician Dondi told him that his diet was too cold; that he ought not to drink water, nor eat fruit and raw vegetables, nor fast, as he often did. But Petrarca had no faith in medicine. He absolutely wrote four books of invectives against physicians He valued Dondi, not as a physician but as a philosopher and he used to tell him so, but Dondi still remained attached to him. The news of Urban V.'s return to Avignon, and of his subsequent death, caused much grief to Petrarca, who had a great esteem for that pontiff. His successor Gregory XI., to whom he was also personally known, wrote to Petrarca, A.D. 1371, a most kind letter inviting him to his court. But Petrarca was unable to move. He was often seized with fits, and sometimes given up for dead. He wrote to Francisco Bruni, the Apostolic secretary, that 'he should not ask the pope for anything, but that if his Holiness chose to bestow on him a living without cure of souls, for he had enough to take care of his own soul, to make his old age more comfortable, he should feel grateful, though he felt that he was not long for this world, for he was waning away to a shadow. He was not in want; he kept two horses, and generally five or six amanuenses, though only three at the present moment, because he could find no more. He could have more easily obtained painters than transcribers. Although he would prefer to take his meals alone, or with the village priest, he was generally besieged by a host of visitors or self-invited guests, and he must not behave to them as a miser. He wanted to build a small oratory to the Virgin Mary, but he must sell or pledge his books for the purpose.' (*Variarum Epistolarum*, the 43rd.) Some months after (January, 1372), writing from Padua to his old college friend Matthew, archdeacon of Liège, he says, 'I have been infirm these two years, being given up several times, but still live. I have been for some time at Venice, and now I am at Padua, performing my functions of canon. I am happy in having left Venice, on account of this war between the republic and the lord of Padua. At Venice I should have been an object of suspicion, whilst here I am cherished. I spend the greater part of the year in the country; I read, I think, I write; this is my existence, as it was in the time of my youth. It is astonishing that having studied so long, I have learnt so little. I hate no one, I envy no one. In the first season of my life, a time full of error and presumption, I despised everybody but myself; in a more mature age I despised myself alone; in my old age I despise almost everybody, and myself most. . . . Not to conceal anything from you, I have had repeated invitations from the pope, the king of France, and the emperor, but I have declined them, preferring my liberty to all.'

In September, 1373, peace was made between Venice and Francis of Carrara, lord of Padua. One of the conditions was that the latter should send his son to Venice to ask pardon and swear fidelity to the republic. The lord of Padua begged Petrarca to accompany his son. Petrarca appeared before the senate, and pronounced a discourse on the occasion, which was much applauded. After his return to Padua he wrote his book, 'De Republica optime administranda,' which he dedicated to his patron and friend Francis of Carrara.

The following year his health grew worse; a slow fever consumed his frame. He went as usual to Arquà for the summer. On the morning of the 18th of July, one of the servants entered his library and found him sitting motionless, with his head leaning on a book. As he was often for whole hours in that attitude, the people of the house at first took no notice of it, but they soon perceived that their master was quite dead. The news of his death soon reached Padua. Francis of Carrara, accompanied by all the nobility of Padua, the bishop and chapter, and most of the clergy repaired to Arquà to attend the funeral. Sixteen doctors of the university bore his remains to the parish church of Arquà, where his body was interred in a chapel which Petrarca had built in honour of the Virgin Mary. Francesco da Brossano, his son-in-law, raised him a marble monument supported by four columns; and in 1667 his bust in bronze was placed above it. On one of the columns the following distich was engraved:—

Inveni requiem; spes et fortuna valete;
Nil mihi vobiscum est, ludite nunc alios.

Petrarca had had two natural children, a son and a daughter. The son died before his father. The daughter, Tullia, married, in her father's lifetime, Francesco da Brossano, a Milanese gentleman, whom Petrarca made his heir. He left legacies to various friends, and among others to Boccaccio, who did not survive him long. The portraits of Petrarca are numerous, but they differ from one another; that which is considered the most authentic is at

Padua, in the Episcopal palace, above the door of the library. It is a fresco painting, which was cut out of the wall of the house of Petrarca at Padua, when it was pulled down in 1581. (Valéry, *Voyages Littéraires.*) An engraving of it is given at the head of the handsome edition of Petrarca's verses by Marsand.

The works of Petrarca are of three kinds: 1, his Italian poetry, chiefly concerning Laura; 2, his Latin poetry; 3, his Latin prose. His Italian poetry, called 'Il Canzoniere,' or 'Rime di Petrarca,' consists of above 300 sonnets, about fifty canzoni, and three short poems, in terza rima, styled 'Trionfo d'Amore,' 'Trionfo della Morte,' and 'Trionfo della Fama.' Petrarca's 'Canzoniere' has gone through more than three hundred editions, with and without notes and commentaries. The best is that edited by Professor Marsand, 2 vols. 4to., Padua, 1819-20, with a biography of Petrarca, extracted from his own works. The character of his poetry is well known. Its greatest charm consists in the sweetness of numbers, 'enlivened by a variety, a rapidity, and a glow which no Italian lyric has ever possessed in an equal degree. The power of preserving and at the same time of diversifying the rhythm belongs to him alone; his melody is perpetual, and yet never wearies the ear. His canzoni (a species of composition partaking of the ode and the elegy, the character and form of which are exclusively Italian) contain stanzas sometimes of twenty lines. He has placed the cadences however in such a manner as to allow the voice to rest at the end of every three or four verses, and has fixed the recurrence of the same rhyme and the same musical pauses at intervals sufficiently long to avoid monotony, though sufficiently short to preserve harmony. It is not difficult therefore to give credit to his biographer, Filippo Villani, when he assures us "that the musical modulation of the verses which Petrarch addressed to Laura flowed so melodiously, that even the most grave could not refrain from repeating them. Petrarch poured forth his verses to the sound of his lute, which he bequeathed in his will to a friend; and his voice was sweet, flexible, and of great compass."' (Foscolo, *Essays on Petrarch*, 'On the Poetry of Petrarch.') That in Petrarca's sonnets there is too much ornament, that he indulges too much in metaphors, that his antitheses are often forced, and his hyperboles almost puerile, all this is true; and yet there is so much delicacy and truth in his descriptions of the passion of love and of its thousand affecting accessories which he brings before the mind of the reader, that he awakens many associations and recollections in every heart, and this is perhaps the great secret of the charm of his poetry, notwithstanding its perpetual egotism. There is much to choose among his sonnets, many of which, especially those which he wrote after Laura's death, are far superior to the rest in loftiness of thought and expression. He borrowed little from the Latin poets, and much from the Troubadours; but his finest imitations are drawn from the sacred writings. He improved the materials in which the Italian language already abounded, and he gave to that language new grace and freshness. No term which he has employed has become obsolete, and all his phrases may be and still are used in the written language. Far inferior to Dante in invention, depth of thought, and in boldness of imagery, Petrarca is superior to him in softness and melody. Dante was a universal poet; he describes all passions, all actions; Petrarca paints only one passion, but he paints it exquisitely. Dante nerves our hearts against adversity and oppression; Petrarca wraps us in soft melancholy, and leads us to indulge in the error of depending upon the affections of others, and his poetry, chaste though it be, is apt to have an enervating influence on the minds of youth. At a more mature age, when man is sobered by experience, Petrarca's poetry produces a soothing effect, and, by its frequent recurrence to the transitoriness of worldly objects, may even have a beneficial moral influence. There are some of his canzoni which soar higher than the rest in their lyric flight, especially the one which begins 'Italia mia,' and which has been often quoted; and another which he wrote in 1333, when a new crusade was in contemplation. His beautiful canzone, or 'Ode to the Virgin,' with which he closes his poetry about Laura, is also greatly admired for its sublimity and pathos.

Petrarca's Latin poetry consists, 1, of the 'Africa,' an epic on the exploits of Scipio in the second Punic war, a dull sort of poem, with some fine passages: it was however much admired at the time; 2, Epistles, in verse, addressed to several popes, for the purpose of urging their return to Rome, and also to several friends; 3, Eclogues or Bucolics, which are acknowledged by himself to be allegorical, and were in fact, like Boccaccio's eclogues, satires against the powerful of his time, and especially against the Papal court of Avignon.

Ginguené, in his 'Histoire Littéraire,' and others, have endeavoured to find the key to these allegories. The sixth and seventh eclogues are evidently directed against Clement VI., and the twelfth, entitled 'Conflictatio,' has also some violent invectives against the Papal court. This circumstance has given rise to strange surmises, as if Petrarca were a secret heretic, an enemy of the church of Rome, belonging to some supposed secret society. We know from Petrarca's own letters, especially those styled 'sine titulo,' that he spoke very plainly to his friends concerning the disorders and vices of the Papal court, which he called the modern Babylon, the Babylon of the west. He says that Jesus Christ was sold every day for gold, and that his temple was made a den of thieves; but we also evidently see that in all these invectives he spoke of the discipline of the Church, or rather of the abuses of that discipline, and not of the dogmas, things which have been often confounded, both by the advocates and the enemies of Rome. Petrarca, like many other observing men of that and the succeeding century, could not be blind to the enormous abuses existing in the Church; but their indignation was poured out against the individuals who fostered those abuses, and they never thought of attacking the fabric itself. This was especially the case in Italy. There might be in that country secret unbelievers and scoffers at revelation, but there were no heretics. There were many who openly charged the pope and his court with heinous crimes, but who at the same time felt a sort of loathing at the very name of heretic or schismatic. The influence of traditional veneration for the authority of the Church, the persuasion of its infallibility, remained, although divested of all devotion, of all enthusiasm, of all respect even for the person of the head of that Church.

Petrarca was not a man of extremes: his dislike of the Papal court of Avignon originated in two feelings, one of honest indignation against its corruptions, and another of national or rather classical attachment to Rome, which made him urge with all his powers of persuasion the return of the head of the Church to a residence in that city. When he spoke of Babylon, he alluded to the captivity of the Jews, to which he compared the residence of the popes at Avignon. Of several popes, such as Urban VI. and Gregory XI., he speaks in his letters with great respect and personal attachment. He went to Rome expressly to attend the jubilee of 1350, and, as he states in his letters to Boccaccio (*Epistolæ Familiares*), for the sake of obtaining the plenary indulgence, and 'with a firm resolve of putting an end to his career of sin.' He had an accident on the road, which made him lame, and which he said was a salutary punishment for his sins. He gives some account of that jubilee, and of the vast number of pilgrims who resorted to Rome on the occasion. After having visited the churches and performed his devotions, he wrote that 'he had now become free from the plague of concupiscence, which had tormented him till then, and that in looking back to his past life, he shuddered with shame.' (*Epistolæ Seniles*, viii. 1.) So much for those who would persuade us that Petrarca was a concealed heretic. His hostility was local and personal; it was directed against Avignon, and not against Rome; against the corrupt dignitaries of the church, not against the Church itself. Petrarca however, although religiously disposed, was far from superstitious. He was one of the few of his age who spurned astrology, and yet, strange to say, a cardinal had nearly persuaded Pope Innocent VI. that he was a magician, because he was familiar with strange books, a very serious charge in those times. Petrarca's letter of advice to Boccaccio, when he thought of turning monk, is a lasting monument of sound religion and good sense.

The Latin Epistles of Petrarca are the most important of his prose writings. We have no Italian prose of his except two or three letters to James Colonna, the autographs of which are now in the possession of Lord Holland, and which show that he was not much in the habit of corresponding in that language. Petrarca's Epistles are very numerous; they embrace a stormy and confused period of nearly half a century, for the history of which many of them afford ample and trustworthy materials. Petrarca was one of the earliest and most enlightened travellers of modern Europe; he was an eye-witness of many important events; he corresponded with kings, emperors, popes, statesmen, and men of learning. His Letters have not been sufficiently noticed by historians: many of them are scattered MSS. in various libraries, and we have no complete edition of them arranged in order of time. Those which have been published are classed as follows:—1, 'Epistolæ de Rebus Familiaribus,' in viii. books; 2, 'De Rebus Senilibus,' written in Petrarca's old age, in xvi. books; 3, one book 'Ad Viros quosdam ex Veteribus Illustriores;' these epistles are addressed to various historical characters of antiquity; 4, one book 'Variarum Epistolarum;' 5, one book 'Epistolarum sine Titulo.' To this last book Petrarca had prefixed a curious preface, in which he says, 'that well knowing truth to be odious to the world, especially in times of corruption, he had taken the precaution of writing the Bucolics in an ambiguous kind of style, in order that their real sense might be understood only by the few, and that for a similar consideration he now has collected in one separate book certain letters written to several friends at various times and upon different occasions, in order that they might not be scattered through the body of his correspondence, and be the means of having the whole condemned. Those who wished to read them would thus know where to find them, and those who thought that they ought to be suppressed, might exclude them from the rest of the collection.'

Professor Levati, of Milan, has composed out of the Epistles of Petrarca a work descriptive of the manners and history of his age, in which he gives copious extracts translated into Italian: 'Viaggi di Francesco Petrarca in Francia, in Germania, ed in Italia,' 5 vols. 8vo., Milan, 1820. This work was severely criticised in the 'Biblioteca Italiana,' vol. xxiii. and xxiv. It is however an entertaining book, containing considerable information concerning Petrarca and his times which is not collected in any other work. Professor Meneghelli, of Padua, published in 1818, 'Index F. Petrarchæ Epistolarum quæ editæ sunt, et quæ adhuc ineditæ;' but his list, as he himself admits, is not complete. Domenico de' Rossetti, of Trieste, has published a bibliography of the works of Petrarca, their various editions, commentators, &c., and he has also edited a biography of Petrarca by his friend Boccaccio. 'Serie cronologica di edizioni delle Opere di Petrarca,' Trieste, 1834.

The prose works of Petrarca, besides those already mentioned, are: 1, 'De Remediis utriusque Fortunæ,' libri ii.; 2, 'De Vitâ Solitariâ,' lib. ii.; 3, 'De Otio Religiosorum,' lib. ii.; 4, 'Apologia contra Gallum;' 5, 'De Officio et Virtutibus Imperatoris;' 6, 'Rerum Memorandarum,' libri iv. In this work, in which he has imitated Valerius Maximus, without however borrowing from him, Petrarca quotes a vast number of facts from antient and modern history, each illustrative of some principle of moral philosophy; it is in fact a treatise of practical ethics. 7, 'De verâ Sapientiâ,' being dialogues between a sophist and an uneducated man. 8, 'De Contemptu Mundi,' being imaginary dialogues between the author and St. Augustin. Petrarca had studied the Latin fathers attentively. 9, 'Vitarum Virorum illustrium Epitome.' Another and ampler work of Petrarca under the same title, of which the one just mentioned is only an abridgement, has remained inedited, but an imperfect Italian translation, by Donato degli Albanzoni, was published at Venice, in 1527. (D. de Rossetti, *Petrarca, Giulio Celso, e Boccaccio, illustrazione Bibliologica,* Trieste, 1828.) 10, 'De Vitâ Beatâ.' 11, 'De Obedientiâ ac Fide Uxoriâ.' 12, 'Itinerarium Syriacum.' 13, Several orations, 'De Avaritiâ vitandâ,' 'De Libertate capescendâ,' &c. Of his Latin style the following judgment is given by an Italian scholar: 'In modelling his style upon the Roman writers, he was unwilling to neglect entirely the Fathers of the Church, whose phraseology was more appropriate to his subjects; and the public affairs being, at that period, transacted in Latin, he could not always reject many of those expressions which, although originating from barbarous ages, had been sanctioned by the adoption of the universities, and were the more intelligible to his readers. In sacrificing gravity he gained freedom, fluency, and warmth; and his prose, though not a model for imitation, is beyond the reach of imitators, because it is original and his own.' (Foscolo 'On the Poetry of Petrarch.') Petrarca's 'Opera Omnia' were published at Basle, in 1581, 2 vols. folio. Biographies of Petrarca have been written by Villani, Vergerio, Tomasini, Leonardo Aretino, and many others: the best are—Baldelli 'Del Petrarca e delle sue Opere,' 2 vols. 8vo.; 'Mémoires pour la Vie de Petrarque, avec des Pièces justificatives,' 3 vols. 4to., Amsterdam, 1746; Foscolo, 'Essays on Petrarch.'

PETRELS, the English name for the *Procellaridæ*, a family of oceanic birds, well known to the seaman when far from the land, and with which his superstition was once more busy than it is now; but even at the present day they are not unfrequently regarded as ominous, and many a hard-a-weather old quarter-master still looks upon *Mother Carey's Chickens* as the harbingers of a storm.

Though zoologists have differed as to the genera to be included in this extraordinary group, they have been pretty well agreed as to the forms which should be congregated in it.

The genus *Procellaria* of Linnæus was formed by that great zoologist for the *Petrels*, and it is closely followed by his genus *Diomedea* (Albatrosses), between which and the *Petrels* there are many points of resemblance both in their structure and their pelagic habits. In the article LARIDÆ, to which family so many ornithologists have referred the *Petrels*, will be found the opinions of most of the leading writers who had then written upon the subject.*

The Prince of Musignano (*Geographical and Comparative List*, 1838) makes the *Procellaridæ* the thirty-fourth family of the birds, and places them between the *Laridæ* and the *Colymbidæ*. The Prince's *Procellaridæ* (European and American only) consist of the genera *Diomedea, Procellaria, Puffinus,* and *Thalassidroma.*

Mr. G. R. Gray (*List of the Genera of Birds*, 1840) makes the *Diomedeinæ* the first subfamily of the *Laridæ*. This subfamily comprehends the genera *Pelecanoides, Puffinus, Daption, Thalassidroma, Wagellus,*† *Procellaria, Diomedea,* and *Prion.*

M. Temminck, in his 'Manuel' (2nd part, 1820), arranges all the *Petrels* under the generic name *Procellaria*, Linn., but divides them into the following sections:—

1.

Petrel properly so called.

Procellaria glacialis.

2.

Procellariæ Puffinus, Anglorum, and *obscura.*

3.

Swallow-like Petrels (Pétrels ndelles).

Procellariæ Pelagica and *Leachii.*

In the 4th part of his 'Manuel' (1840), Temminck admits the genera *Procellaria, Puffinus,* and *Thalassidroma.*

Pelecanoïdes. (Lacépède.)

This is the genus *Haladroma* of Illiger, and the genus *Puffinuria* of Lesson.

The last-named author states that his reason for changing the generic name of the only species which serves as the type of this genus is the uncertainty in which he finds himself as to what is really the genus *Pelecanoïdes* of Lacépède, or *Haladroma* of Illiger. Some strong shades of difference, he observes, appeared to exist between the characters given by these authors and those which he cites, and he further says that he has seen nothing of the small membranous and dilatable pouch, which ought to exist under the lower mandible. The sole species above alluded to he records as *Puffinuria Garnoti*, Less. (*Zool. de la Coq.*, pl. 46; *Procellaria urinatrix*, Gmel.?)

Mr. G. R. Gray gives *Procellaria*, Gm., *Haladroma*, Ill., and *Puffinuria*, Less., as synonyms of *Pelecanoïdes;* and refers, without a query, to *P. Urinatrix*, Gm. (Forst., *Draw.*, t. 88—from which our cut is taken) as the species.

Generic Character.—Bill enlarged, composed of many pieces soldered together, the edges smooth and re entering; the upper demi-bill composed of two pieces, furnished with feathers at the base up to the nostrils, which are very open, forming an oval circle, the aperture of which is above, separated one from the other by a simple internal partition; this partition supports a slight ledge which divides each nasal fossa in half; the enlarged portion of the upper demi-bill goes beyond the lower mandible, and terminates at the contraction of the bill, which is narrow, convex, very much curved, and very robust. The lower mandible is formed equally of two soldered pieces; that of the edge is narrow, inserted in the upper demi-bill; that below is formed by two branches, slightly convex, separated outwards, where the space is filled by a very small and rather indistinct naked skin; the extremity of the mandible is convex on the edges, concave below, and sharp. First and second *quills*, which are the longest, equal; third and fourth rather shorter. *Tail* small, nearly equal, pointed, formed of twelve feathers. *Tarsi* moderate, weak, furnished with small areolated scutella; three anterior toes enveloped in an entire membrane; hind-toe wanting. (Less.)

---

* In the article LARIDÆ, vol. xiii., p. 333, right-hand column, line 35 from the top, for 'Heroudelles,' read 'Hiroudelles.'

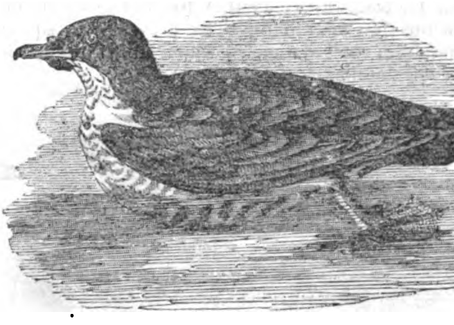
† See post. p. 45.

M. Garnot describes the sole species above noticed, as follows:—Size of the *Blue Petrel*, from the extremity of the bill to the tail, 8½ inches. The plumage has no brilliancy; a blackish-brown on the upper part of the back glazed with a slight tint of blue and a lustrous white on all the foreparts of the body are the two colours which it presents. Beneath the wings, as well as on the sides, the hue is greyish-white.

The head approaches, a little, that of the Pelagic Petrel; the bill is articulated and hooked like that of the Puffins, but differs from that genus in the aperture of the nostrils, which is turned upwards in the form of a heart on a playing card; a partition separates the two nasal conduits; the colour is black; the palmated feet, which want the hind-toe, are of the same colour, and are placed very near the tail, which is intermediate between that of the *Petrels* and the *Grebes*. The eye, which is situated a little above the level of the commissure of the mandibles, has the iris of a red-brown. Total length 8 inches 6 lines.

M. Garnot further describes the tongue as elongated, thick, and dentilated on its edges; the stomach large and occupying nearly the whole abdominal cavity, measured from the cardiac to the pyloric orifice three inches and some lines. The intestine, which forms many duplicatures, or folds, is from 21 to 22 inches long. The two *cæca* are scarcely perceptible. The stomach was full of an oily grey matter, and its internal surface was covered with mucous follicles: the very small gizzard is composed of muscular fibres united by a cellular tissue not of a close texture. The liver, which has not much volume, is divided into two parts. The spleen is very small. The pancreas is but little developed. The testicles were rounded, yellow, and of the size of peas. The larynx, which is three inches long, has no partition in the lower portion, whence M. Garnot concludes that there is no lower larynx; two muscles are there fixed. The heart is small.

Locality and Habits.—This species is found in great flocks along the coast of Peru, flying moderately well in a precipitous manner, and skimming the sea, but it prefers repose on the surface, and dives very frequently, like the Grebes, doubtless for the purpose of capturing the small fish which form its food. M. Garnot thinks that it is intermediate between the *Petrels*, whose bill and feet it very nearly possesses, and the *Grebes*, whose port and habit of diving it has; and hence he proposes for it the name of the *Grebe-Petrel*. The parts between Sangallan and Lima are the localities mentioned by M. Garnot



Pelecanoides Urinatrix.

Mr. Darwin notices *Puffinuria Brerardii* as one more example of those extraordinary cases of a bird evidently belonging to one well-marked family, yet both in its habits and structure allied to a very distinct tribe. 'This bird never leaves the quiet inland sounds,' says Mr. Darwin; 'when disturbed, it dives to a distance, and on coming to the surface with the same movement takes wing. After flying for a space in a direct course, by the rapid movement of its short wings, it drops as if struck dead, and then dives again. The form of the beak and nostrils, length of foot, and even colouring of the plumage, show that this bird is a petrel; at the same time, its short wings and consequent little power of flight, its form of body and shape of tail, its habits of diving, and the absence of a hind toe to its foot, and its choice of situation, make it doubtful whether its relationship is not equally close with the auks as with the petrels. It would undoubtedly be mistaken for one of the former, when seen either on the wing, or when diving and quietly swimming about the retired channels of Tierra del Fuego.' (*Journal and Remarks.*) Prior as is the claim of Lacépède's generic name, there can be no doubt that M. Lesson's designation is much more consonant to the habits of the bird.

Puffinus. (Ray.)

Generic Character.—General characters those of the true Petrels, from which *Puffinus* is distinguished by the bill being longer, by the extremity of the lower mandible, which follows the curvature of the upper, and by the tubular nostrils opening not by a common aperture, but by two distinct orifices.

This is the genus *Thiellus* of Gloger, *Thalassidroma*, Sw., and *Nectris*, Klug.

Example, *Puffinus Anglorum*.

Summit of the head, nape, and all the upper parts of the body generally, the wings, the tail, the thighs, and the borders of the lower tail-coverts, of a lustrous black; all the lower parts of a pure white; the black and white of the sides of the neck are in demi-tints which produce a kind of crescents; bill blackish-brown; feet and toes brown, membranes yellowish. Length nearly 13 inches. Male and female. (Temminck.)

In the 4th part of his 'Manuel,' M. Temminck observes that the natural colour of the feet being badly indicated, he gives it from Graba. The trenchant posterior border of the tarsi and the external toe are deep brown; the other parts of the tarsus are flesh-coloured, and the membranes of a livid tint with brown streaks. Iris deep brown.

Young of the Year.—All the lower parts of a more or less deep ash-colour.

This is the *Procellaria Puffinus* of Brunnich and Latham, *Puffinus Arcticus* of Faber, *Der Nordische und Englische Sturmtaucher* of Brehm, *Pétrel Manks* of Temminck, *Purffingen Fanaw* of the antient British, and *Shearwater Petrel*, *Manks Puffin*, and *Manks Shearwater* of the moderns.

Localities; Habits; Utility to Man; &c.—Willughby says:—'At the south end of the Isle of Man lies a little islet, divided from Man by a narrow channel called the Calf of Man, on which are no habitations, but only a cottage or two lately built. This islet is full of conies, which the Puffins, coming yearly, dislodge, and build in their burroughs. They lay each but one egg before they sit, like the *Razorbill* and *Guillem*, although it be the common persuasion that they lay two at a time, of which the one is always addle. They feed their young ones wondrous fat. The old ones early in the morning, at break of day, leave their nests and young, and the island itself, and spend the whole day in fishing in the sea, never returning or once setting foot on the island before evening twilight; so that all day the island is so quiet and still from all noise, as if there were not a bird about it. Whatever fish or other food they have gotten and swallowed in the day-time, by the innate heat or proper ferment of the stomach is (as they say) changed into a certain oily substance (or rather chyle), a good part whereof in the night-time they vomit up into the mouths of their young, which, being therewith nourished, grow extraordinarily fat. When they are come to their full growth, they who are intrusted by the lord of the island (the earl of Darby) draw them out of the cony-holes; and that they may the more readily know and keep an account of the number they take, they cut off one foot and reserve it, which gave occasion to that fable, that the Puffins are single-footed. They usually sell them for about ninepence the dozen, a very cheap rate. They say their flesh is permitted to be eaten in Lent, being for the taste so like to fish. We are told that they breed not only on the Calf of Man, but also on the Scilly Islands. Notwithstanding they are sold so cheap, yet some years there is thirty pounds made of the young Puffins taken in the Calf of Man, whence may be gathered what number of birds breed there.' Speaking of the flesh, the same author says, that from its extraordinary fatness, it is esteemed unwholesome meat, unless it be well seasoned with salt. Pennant states that they are salted and barrelled, and when they are boiled, are eaten with potatoes. He further says that they quit the isle the latter end of August or beginning of September; and from accounts then lately received from navigators, he observes that he has reason to imagine that, like the Storm-finch, they are dispersed over the whole Atlantic Ocean. He says it inhabits also the Orkney Isles, where it makes its nest in holes in the earth near the shelves of the rocks and headlands; it is, he says, called there the *Lyre*, and is much valued, both on account of its serving as food and for its feathers. The inhabitants, he adds, take and salt them in August for winter provisions, when they boil them with cabbage: they also take the old ones in March; but they are then poor, and not so well tasted as the young, and he makes their first appearance to be in February.

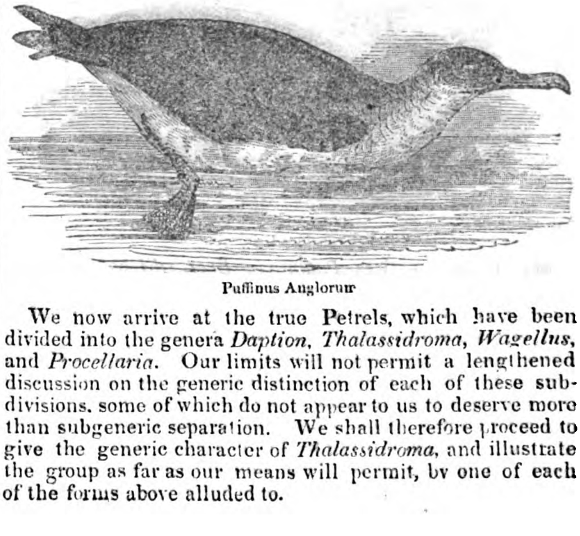
Mr. Selby (*Illustrations of British Ornithology*), who gives *Lyre*, *Shearwater*, and *Scrabe* as the provincial names of the bird, remarks, that from the accounts transmitted to us by the authors above quoted, this species appears, at the time they wrote, to have resorted in great numbers to the Calf of Man; but from the information which Mr. Selby obtained, confirmed by the testimony of Sir W. Jardine (who visited the Isle of Man a few years ago with the express view of ascertaining this and some other points connected with ornithology), it seems now to be entirely deserted by those birds, a circumstance in all probability occasioned by the wanton and greedy destruction of their eggs and young. Mr. Selby, not having extended his inquiries to the Scilly Islands, is unable to say whether it is now to be found there; but he states that it is still abundant in the Orkneys, where it breeds in holes scratched in the earth that fills up the interstices of the rocks and bold headlands, and is, according to Low, the main object of pursuit with the *Rockmen*, who endanger their lives in climbing the most awful precipices for the eggs and young of water-fowl. 'Like the rest of the genus,' continues Mr. Selby, 'this bird lays but one white egg, of a rounded form, being equally obtuse at each end, and not inferior in size to that of a domestic fowl. It arrives at its breeding station in February or March; and soon after August, when its young is able to fly, deserts it for the open sea, migrating, as the winter approaches, in a southerly direction towards the coast of Spain, the Mediterranean, &c. In Britain it is almost entirely confined to the western coast, being of very rare occurrence on the eastern, where I have only met with one individual, which was shot upon an excursion to the Fern Islands.' The same author thinks that Willughby and Pennant are mistaken in attributing the stillness observed in the Calf of Man during the day to the absence of the birds at sea, the real cause, in Mr. Selby's opinion, being the repose of the birds in their burrows to prepare for their activity at evening twilight and morning dawn.

Mr. Gould (*Birds of Europe*) remarks that it is evident Mr. Selby is not aware that this species is, during the summer months, nearly as abundant on the coasts of South Wales as it formerly was in the Calf of Man. Four dozens, apparently captured by hand, were sent to Mr. Gould from this locality, with an intimation that he could have as many more. It appeared from the information obtained by him, that the birds visit these localities for the purpose of incubation during the early part of the spring, when they resort to deserted rabbit-burrows, crevices of the rocks, &c., wherein they deposit their single white egg, and the birds then fall an easy prey to the fishermen and others. He further says that they retire southwards, after the breeding season, even beyond the Mediterranean, where, in consequence of the increased temperature, they find a greater supply of food. The coasts of Norway and the shores of the Baltic, he adds, although not without the presence of this species, appear to be much less frequented by it than our own islands. M. Temminck, in the 2nd part of his 'Manuel,' mentions Ireland* as one of the localities, and notes the species as found on the coasts of Norway, according to the testimony of some voyagers, but not in the Baltic, and rarely on the coasts of Holland and France. In the 4th part of the same work, he states that it is common in the Feroe Isles; and that it migrates in more or less considerable numbers along our maritime coasts, mentioning it as rare in Iceland, and as not visiting the coasts of Norway. He adds that it is common on the banks of Newfoundland, and that it is also found in the south, for it is accidentally seen in the Mediterranean. He received an individual killed on the Bosphorus, and another from the Adriatic; the only difference was in the slenderness of the bill as compared with northern specimens. Mr. Gould figures three species in his great work (*Birds of Europe*): the bird above described; the *Dusky Shearwater* (*Puffinus obscurus*); and the *Cinereous Shearwater* (*Puffinus cinereus*), Stephens. With regard to the last, Mr. Gould remarks, that if it should ultimately appear that the bird obtained by Mr. Strickland from the Tees mouth, and characterised by him as a new species under the name of *Puffinus fuliginosus* (*Zool. Proc.*, 1832), is identical with the young of *Puffinus cinereus*, which is by no means unlikely, and if a bird apparently in the adult plumage, subsequently obtained by the same gentleman, should prove to be the adult of this species, we shall have, with the addition of a specimen obtained by Mr. Selby, three examples of British-killed specimens of this genus. Mr. Gould further observes with respect to the specimens forwarded by Mr. Strickland, and which he has figured, that these two birds, although agreeing in their admeasurements with each other, differ slightly from a specimen of *Puffinus cinereus* sent to Mr. Gould by M. Temminck as an undoubted example of that species, Mr. Strickland's specimens being less in all their admeasurements; and Mr. Gould adds, that if he could have discovered any difference in the markings of their plumage, he should have had no hesitation in regarding them as distinct: as it is, Mr. Gould figures Mr. Strickland's specimens, a young one and an adult, as *Puffinus cinereus*, with a ? M. Temminck refers to Mr. Gould's figure of the adult for *Puffinus cinereus*, without any mark of doubt.

Puffinus cinereus, according to Mr. Darwin, is common to Cape Horn and the coast of Peru, as well as Europe, and generally frequents the inland sounds. 'I do not think,' adds Mr. Darwin, 'I ever saw so many birds of any other sort together, as I once saw of these behind the island of Chiloe; hundreds of thousands flew in an irregular line for several hours in one direction. When part of the flock settled on the water the surface was blackened, and a noise proceeded from them, as of human beings talking in the distance. At this time the water was in parts coloured by clouds of small crustacea. At Port Famine, every morning and evening, a long band of these birds continued to fly with extreme rapidity up and down the central parts of the channel. I opened the stomach of one (which I shot with some difficulty, for they were very wary), and it contained a small fish and seven good sized prawn-like crabs. (*Journal and Remarks*.)

Mr. Gould describes a species, *Puffinus Affinis*, from New South Wales. (*Zool. Proc.*, 1837.) It is closely allied to *P. obscurus*, but somewhat smaller.

The Shearwaters generally have the wings well developed and fly rapidly, skimming over the waves, whence they pick up small fishes, crustaceans, mollusks, and in short any marine animals which they can master. While thus employed they approach nearly in their habits to the true Petrels, spurning as it were the water with their feet (which are placed far backwards) as they fly, and using them as a support while they snatch up their prey. They squirt the oily matter from their stomachs, when surprised by an intruder, in self-defence.



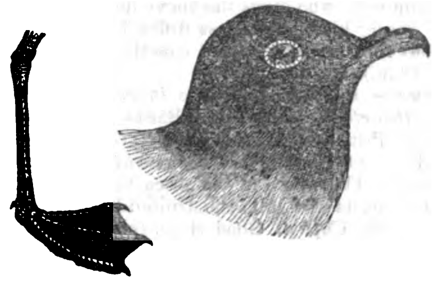
Puffinus Anglorum

We now arrive at the true Petrels, which have been divided into the genera *Daption*, *Thalassidroma*, *Wagellus*, and *Procellaria*. Our limits will not permit a lengthened discussion on the generic distinction of each of these subdivisions, some of which do not appear to us to deserve more than subgeneric separation. We shall therefore proceed to give the generic character of *Thalassidroma*, and illustrate the group as far as our means will permit, by one of each of the forms above alluded to.

---

* The Cinereous Shearwater (*Procellaria Puffinus*, Linn.) is noted as an Irish bird by Mr. Thompson. It was taken in August, 1835, by a boy who saw it scrambling towards a hole at the base of a cliff near Dungarvan, county of Waterford. They are called *hagdowns* by the fishermen. (*Zool. Proc.*, 1837.)

Generic Character of Thalassidroma.—*Bill* shorter than the head, much compressed in front of the nasal sheath, with the tip of the upper mandible suddenly curving and hooking downwards, and that of the lower one slightly angulated and following the curve of the upper. *Nostrils* contained in one tube or sheath, but showing two distinct orifices in front. *Wings* long and acuminate, with the first quill shorter than the third, the second being the longest. *Tail* square or slightly forked. *Legs* having the tarsi rather long and slender, reticulated. *Feet* of three toes united by a membrane; hind toe represented by a small straight dependent nail. (Gould.)

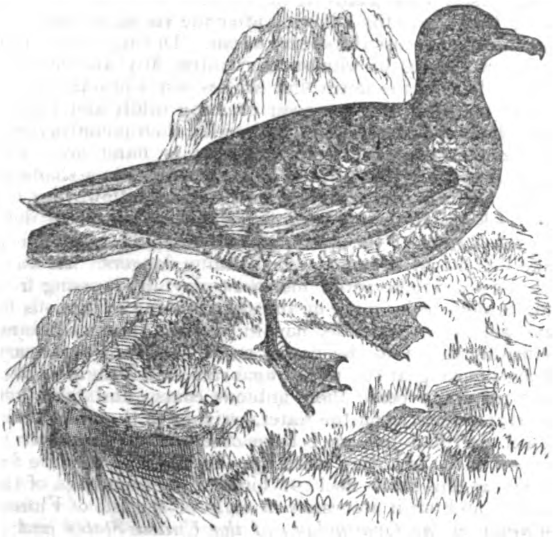


Head and foot of Thalassidroma pelagica.

The group generically subdivided as above, or rather the most of them, have been regarded as the indicators of storm and tempest. Rapidly spurning the billows as they skim along the undulating waves, they are ever on the watch for what the troubled water may offer to them, and they congregate in the wake of the sea-going ship not so much perhaps for shelter as for what is turned up from the furrow ploughed by the keel. Mr. G. Bennett, during his voyage, observed that the Cape Petrels, Albatrosses, and other birds followed the ship during the whole of the night, reposing for a short period on the water, but seldom remaining long on the waves. They usually alighted for food, and soon resumed their flight. Marked birds were seen about the ship for days together when the strong gales carried the vessel at a rapid rate through the water. Cape Petrels and Albatrosses were seen flying near the stern as late as midnight, and it was not unusual to hear the twittering note of the Stormy Petrel (*Thalassidroma pelagica*) under the stern during the night. (*Wanderings in New South Wales*, vol. i.)

Daption.

Example, *Daption Capensis*, Stephens; *Procellaria Capensis*, Linn.; *Cape Pigeon* of the English; *Peintada* of the Portuguese.



Daption Capensis.

Description.—Plumage variegated with brown and white. The total length of one measured by M. Lesson was thirteen inches, that of the tube of the nostrils six lines. The testicles were rather deep grey, the larynx had two muscles proper to it, and the total length of the intestinal tube was 47 inches. M. Garnot communicated to M. Lesson a species which the latter believed to be new, with an elaborate description and anatomical details, which M. Lesson quotes at length.

Captain P. P. King, in a letter to Mr. Broderip from New South Wales (April, 1834), states that from the meridian of the island of St. Paul's, on about the parallel of 40° S. lat., the ship was daily surrounded by a multitude of oceanic birds. Of the *Petrel tribe*, the *Cape Pigeon*, *Procellaria Capensis*, Linn., was most abundant; but *Proc. vittata* (vel *cærulea*)—*Prion*—frequently was observed; as was also a small black Petrel which Captain King did not recollect to have before seen. (*Zool. Proc.*, 1834.) The same author states that the *Pintado Petrel* (the species now under consideration), seems to be spread over the whole of the southern hemisphere. (*Zool. Journ.*, vol. iv.)

Thalassidroma. (Vigors.)

This is the genus *Hydrobates* of Boie.

Mr. Selby remarks that the members of this genus, which are all of small size, have been very properly separated by Mr. Vigors from the rest of the Petrel group. They are, he observes, birds of nocturnal or crepuscular habits, and are seldom seen except in lowering weather, or during storms, when they frequently fly in the track of ships. At other times, and in clear weather, they remain concealed during the day in the holes of rocks, rat-burrows, &c., and only come forth at nightfall in search of food, consisting of marine crustaceans, small mollusks, and other oily animal matter which they find floating on the surface of the ocean. Their flight equals in swiftness that of the Swallow tribe, which they resemble in size, colour, and general appearance. All the known species are of a dark hue, more or less relieved with white, and are widely distributed, some being found in both hemispheres, and in a variety of climate. They breed in the crevices of rocks, caverns, &c., and, like the *Fulmars* and *Shearwaters*, lay but one egg, which is white, and comparatively large. (*Illustrations of British Ornithology*, vol. ii.)

Examples. — *Thalassidroma pelagica*, and *Thalassidroma Wilsonii*.

Description of Thalassidroma pelagica.—Head, back, wings, and tail dull black; lower parts sooty black; a large transverse band of pure white on the rump; scapulars and secondary quills terminated with white; tail and quills black, the first quill not the longest, but shorter by four lines than the second and third, which is the longest; bill and feet black; iris brown. The tail is square, and the tips of the wings reach but very little beyond its point. The length of the tarsi is ten lines. Total length five inches six lines. (Male and female.)

Young of the Year.—These have the tints less deep, and the edges of the feathers sooty or rusty: in other respects they resemble the adults.

Localities.—More common in North America than in Europe; found on the coasts of England and Scotland; rather common at the Orcades and Hebrides; more abundant in the island of Saint Kilda; wanders rarely on the coasts of the ocean, and very accidentally on the lakes of the centre of Europe. (Temminck.) Mr. Selby states that they are found upon the seas surrounding Britain at all seasons of the year, and that they have been ascertained to breed not only upon the Shetland and other northern islands of Scotland, but upon the rocky coast of the north-west of Cornwall at the opposite extremity of the kingdom. The geographical distribution of this species has, he adds, been supposed to be very extensive, but the discovery of other species very closely allied to it both in size and colour (and only to be distinguished by narrow inspection and comparison) in various parts of the Atlantic and Pacific Oceans, makes it more than probable that these latter have been mistaken for it, and that its distribution is in fact much more limited, being in all likelihood confined to the European seas.

The bird above described, which is considered to be the smallest of the web-footed birds, is the *Procellaria pelagica* of Linnæus; *Uccello delle Tempeste* of the modern Italians; *Oiseau de Tempête*, *Pétrel*, and *Pétrel Tempête* of the French and Temminck; *Ungewitter Vogel*, *Kleinster Sturmvogel*, and *Meer Peters Vogel* of the Dutch; *Storm Zwalu* of the Netherlanders; *Stromwaders Vogel* of the Swedes; *Soren Peder*, *St. Peders Fugl*, *Vestan-vinds* or *Sonden-vinds Fugl*, and *Uveyrs Fugl* of the Norwegians; *Cas gan Longwr* of the antient British; *Common Storm Petrel*, *Stormy Petrel*, and *Storm-finch* of the modern

British, who call the species also (provincially) *Little Petrel, Mitty, Assilag, Spency, Sea-swallow, Allamouty, Witch*, and (mariners especially) *Mother Carey's Chickens*, a title which is not confined to *Procellaria pelagica*, but is shared by and more generally applied to the more oceanic species, such as *Thalassidroma Wilsonii*, &c.

This, or some other species of *Thalassidroma*, is in all probability the *Cypselus* of Pliny, who describes (*Nat. Hist.*, x. 39) the swallow-like appearance of his *Cypseli*, their nesting in rocks, their wide spread over the sea, and says that however far ships go from land, these birds fly around them.

Habits, Food, Reproduction, &c.—The habits of this species very much resemble those of the other Petrels. Mr. Selby remarks that most authors state that it lays but one egg, which M. Temminck describes as being pure white, nearly round, and of the shape of an owl's. Mr. Selby believes that a single egg is the general law, but he refers to Mr. Scarth's paper in the 'Linnean Transactions' (xiii.). The latter gentleman found a nest in passing over a track of peat-moss near the shore upon an uninhabited islet in Orkney. He was directed to it by the low purring noise of the female, and found *two* pure white eggs, of a very large size* as compared to the bird. Upon seizing the old one, she squirted out a very rancid oily substance. Upon taking her home, she was put into a cage, and various worms were offered to her, all of which she refused. At the end of four days, Mr. Scarth saw that she occasionally drew the feathers of her breast singly across or rather through her bill, and appeared to suck an oily substance from them. Upon this, he smeared her breast with train oil, and as she greedily sucked it, he repeated the smearing twice or thrice a day for a week. He then placed a saucer containing oil in the cage, in which she regularly dipped her breast, and then sucked her feathers as before. Thus he kept her alive for three months. Mr. Selby observes that some authors have stated that the young, as soon as hatched, are conducted to the water; but this he says is a mistake, as they remain in the holes till fully able to fly, which does not take place for some weeks, and during this time they are fed by the parents with oily matter ejected from their stomachs. 'Instances,' continues Mr. Selby, 'frequently occur of its being found rather far inland, either dead or in an exhausted and dying state; but the cause of such mortality has not hitherto been satisfactorily accounted for; it may however arise from weakness, occasioned either by old age or accidental illness, rendering it unable to contend with the autumnal and wintry blasts, during which period such instances are most frequent; and this is rendered more probable by its being commonly in an emaciated condition. The flight of the Storm-Petrel is remarkably swift, and is equalled by few of the feathered race. It is often seen darting from wave to wave, at intervals dipping its bill into the water as if in search of insects, or picking up food, during which it will stand as it were upon the summit of the billow with wings expanded and raised, but it is very rarely seen to alight for swimming, and is totally unable to dive, a faculty attributed to it in an eminent degree by some of the earlier writers.' In December, 1823, whilst sailing on the Thames, we saw one of these birds in the middle of the river, just below the Tower of London. It was disporting on the wing just above the surface of the water, which was very rough, and ever and anon settled on it, rising again almost immediately. It had blown a gale (which still continued when the bird was seen) for twenty-four hours. Many persons were in unsuccessful pursuit of it, they being apparently unacquainted with its habits, and taking it for a stray and wearied land-bird which was constantly dropping into the water.

M. Temminck (*Manuel*, 4th part) observes that M. Graba presumes that the moult of this species is double, and that in autumn their plumage has some obscure spots. M. Temminck further remarks that the variety found at Feroe differs from that found accidentally on his coasts in the want of the white on the scapulars and secondaries of the wings; in other respects there is no marked disparity. This is the *Hydrobates Feroensis* of Brehm, and is in all probability that alluded to by Brunnich, when he tells us that the inhabitants of the Feroe Isles make the bird serve as a candle, by drawing a wick through the mouth and rump, which, being lighted, is fed by the fat and oil of the body.

Thalassidroma Wilsonii.—Description.—Head and all the lower parts sooty black; back, scapulars, and wings black; some of the great wing-coverts bordered with whitish; all the upper tail-coverts, and, in some individuals, a part of the feathers of the thighs also or some of the lower coverts, pure white; tail nearly square, only slightly emarginate, the three lateral feathers white at their base; wings exceeding the tail more than an inch; bill and feet (tarsi 15 lines long) black; on the membranes a long yellow stain and the edges of the toes finely bordered with that colour; iris black; extremity of the nasal tube turned up. Total length of the bird 6 inches 3 or 4 lines. (*Both sexes in perfect plumage.*)

M. Temminck, who gives the above description, observes that the young birds doubtless differ but little from the adults; but they are not as yet exactly known. (*Manuel*, 4th part, 1840.)

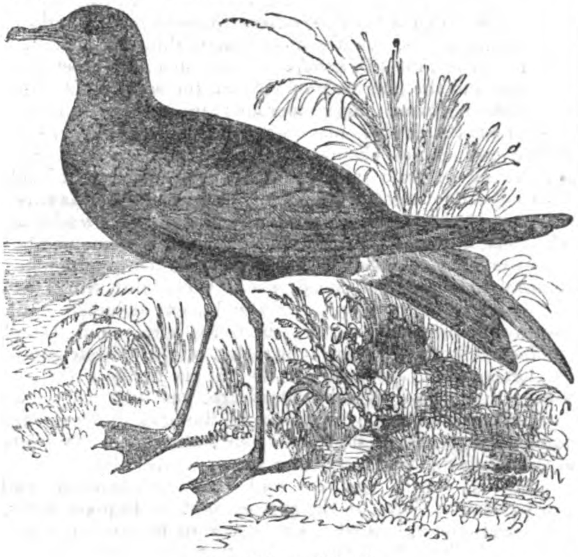
This species appears to be the *Procellaria pelagica* of Wilson; *Procellaria oceanica* of Banks; *Procellaria Wilsonii* of the Prince of Musignano; *L'Oiseau Tempête* of Buffon, 'Enl.' 993; and *Pétrel échasse* of Temminck.

Localities.—The whole of America to Cape Horn; common on the coasts of Chili, the United States, and Brazil; more rare at the Cape of Good Hope than *Procellaria pelagica;* shows itself accidentally on the coasts of Spain and in the Mediterranean. (Temminck, *Manuel*, 4th part.)

Habits, Food, Reproduction, &c.—Nuttall, who enumerates their vulgar names of Stormy Petrels, Devil's Birds, and Mother Carey's Chickens with remonstrance, well describes their habits. 'On the edge of soundings, as the vessel' loses sight of the headlands, flocks of these dark, swift flying, and ominous birds begin to shoot around the vessel, and finally take their station in her foaming wake. In this situation, as humble dependents, they follow for their pittance of fare, constantly and keenly watching the agitated surge for floating mollusca, and are extremely gratified with any fat kind of animal matter thrown overboard, which they instantly discover, however small the morsel, or mountainous and foaming the raging wave on which it may happen to float. On making such discovery, they suddenly stop in their airy and swallow-like flight, and whirl instantly down to the waters. Sometimes nine or ten thus crowd together like a flock of chickens scrambling for the same morsel, at the same time pattering on the water with their feet, as if walking on the surface, they balance themselves with gently fluttering and outspread wings, and often dip down their heads to collect the sinking object in pursuit. On other occasions, as if seeking relief from their almost perpetual exercise of flight, they jerk and hop widely over the water, rebounding as their feet touch the surface with great agility and alertness. There is something cheerful and amusing in the sight of these little voyaging flocks, steadily following after the vessel, so light and unconcerned across the dreary ocean. During a gale it is truly interesting to witness their intrepidity and address. Unappalled by the storm that strikes terror into the breast of the mariner, they are seen coursing wildly and rapidly over the waves, descending their sides, then mounting with the breaking surge which threatens to burst over their heads, sweeping through the hollow waves as in a sheltered valley, and again mounting with the rising billow, they trip and jerk sportively and securely on the roughest sea, defying the horrors of the storm, and like magic beings seem to take delight in braving overwhelming dangers. At other times we see these aerial mariners playfully coursing from side to side in the wake of the ship, making excursions far and wide on every side, now in advance, then far behind, returning again to the vessel as if she were stationary, though moving at the most rapid rate. A little after dark they generally cease their arduous course, and take their interrupted rest upon the water, arriving in the wake of the vessel they had left, as I have observed, by about 9 or 10 o'clock of the following morning. In this way we were followed by the same flock of birds to the soundings of the Azores, and until we came in sight of the Isle of Flores.' (*Manual of the Ornithology of the United States and of Canada.*) Temminck states that their food consists of the seeds of some marine plants, small testaceans, mollusks, &c.; Wilson says that they feed on the gelatinous spora of the Gulf-weed (*Fucus natans*), as well as small fish, barnacles, &c. Nuttall informs us that these Petrels breed in great numbers on the rocky shores of the Bahama and the Bermuda islands, and along some parts of the coast of East Florida and Cuba. Mr. Audubon informed him that they also breed in large flocks on the mud and sand islands off Cape Sable in Nova Scotia, burrowing downwards from the surface to the depth of a foot or more. They also commonly employ the holes and cavities of rocks near the sea for this purpose. 'The eggs,' says Nuttall, in continuation, 'according to Mr. Audubon, are three, white and translucent. After the period of incubation they return to feed their young only during the night, with the oily food which they raise from their stomachs. At these times they are heard through most parts of the night, making a continued cluttering sound like frogs. In June and July, or about the time that they breed, they are still seen out at sea for scores of leagues from the land, the swiftness of their flight allowing them daily to make these vast excursions in quest of their ordinary prey; and hence, besides their suspicious appearance in braving storms, as if aided by the dark ruler of the air, they breed, according to the vulgar opinion of sailors, like no other honest bird, for taking no time for the purpose on land, they merely hatch their egg under their wings, as they sit on the water!'

---

* About the size of a blackbird's.



Thalassidroma Wilsonii.

Fulmarus. (Leach.)

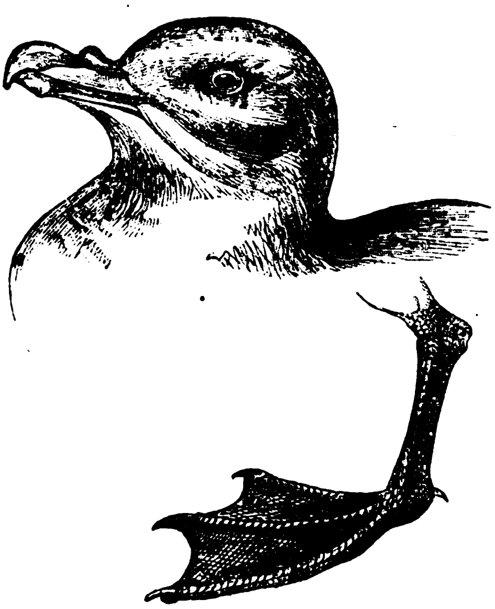
Mr. G. R. Gray gives *Wagellus*, Ray, as the generic name of this form, and Linnæus quotes *Wagellus Cornubiensium* as a synonym of the species which we are about to illustrate. But both Ray and Willughby (to say nothing of other parts of their descriptions) describe the bill of their bird as black, which appears not to be the colour of that of *Fulmarus glacialis*, either in the young or the adult state. Willughby's figure (t. 66), though not a good one, can hardly be taken for a Fulmar; the nostrils are not represented as tubular, nor the bill itself as large; and there is nothing to lead the observer to suppose that the figure was intended for that bird. Mr. Selby quotes the figure and description of Willughby as referrible to *Larus argentatus* of Brunnich.

Example, *Fulmarus glacialis*.

This species has been considered the type of the restricted genus *Procellaria*, Linn., by those who confine the subdivision of that genus to the genera *Procellaria*, *Puffinus*, and *Thalassidroma*. The bill of the *Fulmar* is stout, thick, with the upper mandible considerably hooked at the tip (where it is also dilated) and sulcated. The lower mandible is straight and slightly truncated. The nostrils are united in a single tube. The legs are moderate, and a sharp claw exists in the place of a hind toe.

Description.—Head, neck, all the lower parts, rump, and tail pure white; back, scapulars, wing-coverts and secondaries pure bluish-ash; quills bright grey brown; tail well rounded, conical; bill bright yellow tinged with orange on the nasal tube; iris and feet yellow. Length 16 inches. (*Both sexes, summer plumage.*)

Young of the Year.—The whole body bright grey clouded with brown; feathers of the wings and tail terminated by a deeper brown; the quills and caudal feathers have only a tinge of grey-brown; in front of the eyes an angular black spot; bill and feet yellowish ash. (Temminck.)

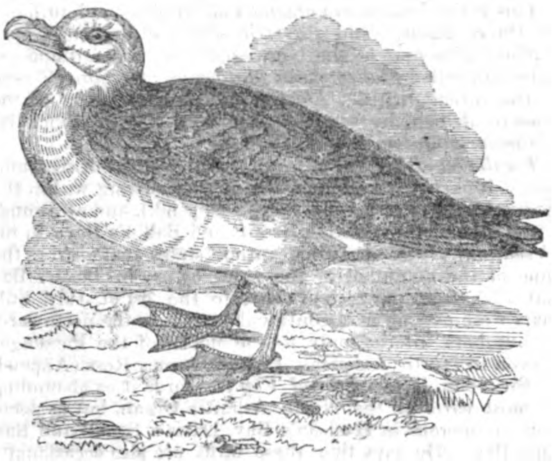


Head and foot of Fulmar.

This is the *Procellaria glacialis* of Linnæus and authors; *Le Pétrel Fulmar* and *Pétrel de l'île de Saint Kilda* of Buffon; *Hav-hest* of the Norwegians, by whom it appears to be also called *Mallemoke* or *Mullemuke; Gwylan y Graig* of the antient British; *Fulmar* and *Fulmar Petrel* of the modern British, by whom it is also named (provincially) *Mallemuck, Malmoke*, and *Mallduck*.

Localities.—The Polar regions principally during summer. It is noted by Major Sabine as occurring within the Arctic Circle (Parry's *First Voy.*, Append.), and as abundant at all times in Davis's Straits and Baffin's Bay: in his *Greenland Birds* the same author states that during the time of the detention of the ships by ice in Jacob's Bay (lat. 71°), from the 24th of June to the 3rd of July, Fulmars were passing in a continual stream to the northward, in numbers inferior only to the flocks of the Passenger Pigeon in North America. Captain James Ross (Append. to Sir John Ross's *Second Voy.*) records it as abounding in most parts of the North Atlantic Ocean, but as peculiarly numerous in Hudson's Bay, Davis's Strait, and Baffin's Bay. He says that these birds are also occasionally met with to the westward of Lancaster Sound, and in Regent's Inlet, following the whale ships, and availing themselves of the success of the fishermen, by feeding off the carcass of the whale after it has been deprived of its blubber and turned adrift. Temminck places the species always on the shelves and floating ice of the pole, and says that it is very accidental on the coasts of England and Holland; but that the seas of the Arctic Pole are covered with it at great distances from land. Mr. Selby (*Illustrations of Brit. Ornith.*) informs us that the steep and rocky St. Kilda, one of the western islands of Scotland, is the only locality within the British dominions annually resorted to by the *Fulmar*, the rest of the Scottish and our more southern coasts being rarely visited even by stragglers. Mr. Gould (*Birds of Europe*) observes, that although the Polar regions constitute its native locality, it is nevertheless found, but in much less abundance, in more temperate climates, such as the northern seas of Europe and America, extending itself throughout the lengthened coast of Norway, and not unfrequently Holland and France. It frequents also, he adds, the northern isles of Great Britain, resorting to the Orkneys and Hebrides for the purpose of breeding, but particularly to the island of St. Kilda.

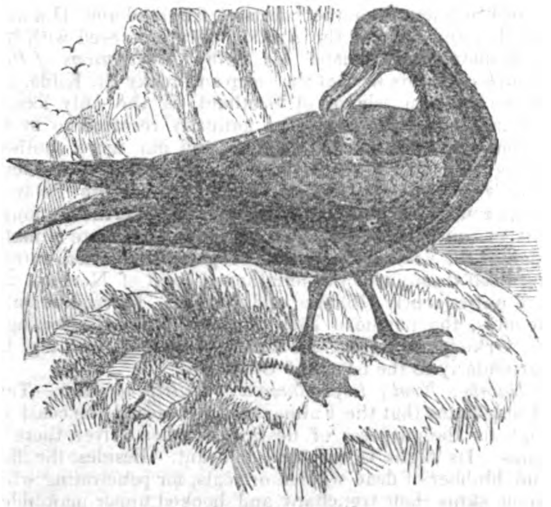
Habits; Food; Reproduction; Utility to Man.—Temminck states that the Fulmar never comes to the coast except for the purposes of nesting, or when driven there by gales. Its flight is easy and buoyant. Besides the flesh and blubber of dead whales or seals, for penetrating whose thick skins their trenchant and hooked upper mandible is admirably formed, barnacles and other parasites which attach themselves to the whales, mollusks, &c., form their food. Captain James Ross (*loc. cit.*) says that the bird is of essential service to those employed in the capture of the whale, by guiding them to those places where the whales are most numerous, and by giving notice of the first appearance of those animals at the surface of the water, by crowding to the spot from all quarters. The *Fulmar* also attends the fishing-vessels on the banks of Newfoundland, where it is called *John Down*, for the offal of the cod-fish, and is often taken with a hook baited with a piece of cod's liver or flesh. At St. Kilda they breed gregariously in the caverns and holes of the rocks; a single white large egg, with a very brittle shell, is deposited by the female, and the young, which are hatched about the middle of June, are fed with oily matter disgorged by the parents. As soon as they are fledged they are eagerly sought by the *cragsmen*, who scale the precipitous cliffs for them at the risk of their lives, for the sake of their down, feathers, and oil. 'No bird,' says Pennant, 'is of such use to the islanders as this; the Fulmar supplies them with oil for their lamps, down for their beds, a delicacy for their tables, a balm for their wounds, and a medicine for their distempers. The Fulmar is also a certain prognosticator of the change of wind; if it comes to land, no west wind is expected for some time; and the contrary when it returns and keeps the sea.' These birds are said to be salted for winter provision by the inhabitants of Baffin's and Hudson's Bay. Like the other Petrels, the Fulmars eject oil through their nostrils in self-defence, and it therefore becomes, as Mr. Selby observes, an essential point that they should be taken and killed by surprise, in order to prevent the loss of a liquid so valuable to those who capture them.



Fulmarus glacialis.

Procellaria. (Linn.)

The type of this genus, as restricted by Mr. G. R. Gray, is *Procellaria Æquinoctialis*, Linn.; *The Great Black Petrel* of Edwards.



Procellaria Æquinoctialis.

Mr. Darwin, in his valuable 'Journal and Remarks' (*Voy. of Adventure and Beagle*), remarks that the southern seas visited by the expedition are frequented by several species of Petrels. The largest kind, *Procellaria gigantea*, or Nelly (*Quebrantahuesos*, or *Break-bones*, of the Spaniards), is, he observes, a common bird, both in the inland channels and on the open sea. 'In its habits and manner of flight,' continues Mr. Darwin, 'there is a very close resemblance with the Albatross, and as with the latter bird a person may watch it for hours together without seeing on what it feeds, so it is with this petrel. The *Break-bones* is however a rapacious bird, for it was observed by some of the officers at Port S. Antonio chasing a diver. The bird tried to escape, both by diving and flying, but it was continually struck down, and at last killed by a blow on its head. At Port St. Julian also these great petrels were seen killing and devouring young gulls.' The same author adds that the Spaniards were probably aware of the rapacity of this petrel, for 'Quebrantahuesos' means properly an osprey. These large petrels are called *Mother Carey's Geese* by the sailors.

Diomedea. (Linn.) [ALBATROSS.]

Captain P. P. King, R.N., in his letter to Mr. Broderip above alluded to, says, 'Of the genus Diomedea the species which I regarded as the *D. spadicea, chlororhynchos*, and *fuliginosa* of authors, were the most remarkable. Near Tristan d'Acunha the first (*D. spadicea*) most abounded; between the Cape and the longitude of 30° east, the second (*D. chlororhynchos*) became more numerous; and in the neighbourhood of St. Paul's their place was supplied by *D. fuliginosa*. Where one species abounded, the others were only occasionally seen; from which it may be inferred that each species breeds in distinct haunts. Occasionally two or three varieties of the *D. exulans*, Linn., the *large wandering Albatross*, attended the ship, but they rarely remained beyond the day. *D. exulans* varies very much in plumage; generally however the head, neck, back, and wings are more or less mottled-grey, and the breast, abdomen, vent, and uropygium snowy white; the bill is horn-coloured, and the feet yellow. We saw a bird that might be referred to M. Lesson's *D. epomophora*, if that is really a distinct species. Another, of very large size, was near us for two days, which, with the exception of the back of the wings and tips of the under-side of the pen feathers and extremity of the tail being black, was of a snowy white colour.'

Drawings of *D. spadicea* and *D. chlororhynchos*, and descriptions of three of the species sent by Captain King, were read and exhibited. The descriptions agreed essentially with those from the same specimens in 'Wanderings in New South Wales,' by Mr. G. Bennett, who was a fellow-voyager with Captain King. The Report goes on to state that the reference of these to the species quoted is provisional only, as they differ in some important particulars from the original description of those species; it is therefore probable that they are rather to be viewed as indicating races hitherto unknown to zoologists. (*Zool. Proc.*, 1834.)

The author of the 'Wanderings' above noticed states that the known species are, *D. exulans, D. spadicea, D. chlororhynchus, D. fuliginosa;* and also, as enumerated by Cuvier, *D. brachyura* (Tem.), and *D. melanophris* (Tem.); to these two last Mr. Bennett had no opportunity of referring. He gives a description of a species found at Bass's Straits, among others, and has a chapter containing much interesting observation on the habits of the Albatrosses and the mode of capturing them. They appear to be unsparing in their voracity, for Mr. Bennett saw one which was shot dead instantly fallen upon by its companions, eager to make it their prey. The excretory duct of the nasal gland of the *Wandering Albatross* (*D. exulans*) was traced by Mr. Bennett for nearly two inches under the external plate of the upper mandible, in a direction towards the nostrils, but inclining slightly upwards, until he lost sight of it among the cellular substance of the bone.

Habits, Reproduction, &c.—Captain Carmichael (*Linn. Trans.*, vol. xii.) gives an account of the breeding of these birds, from personal observation, in the island of Tristan d'Acunha. As he and his party walked down the mountain on their return, they passed among flocks of Albatrosses engaged in the process of incubation or tending their young. Four species (*Diomedea spadicea, exulans, chlororhynchus*, and *fuliginosa*) breed on the island; none of them hatch more than one egg at a time. The two former give themselves no trouble, it appears, in constructing their nest, merely choosing a dry spot of ground, and giving it a slight concavity, to prevent the egg from rolling out of its place.

The egg is white, very large, uncommonly long in proportion to its diameter, and nearly of equal thickness at both ends. The black Albatrosses (*D. fuliginosa*) were gregarious when Captain Carmichael visited the island (January), and built their nests, which were constructed of mud, raised five or six inches and slightly depressed at top, close to each other. He counted upwards of a hundred in an area of half an acre. The birds stood motionless as statues on their respective hillocks till the party approached close to them, when they set up the strangest clattering with their beaks, and, on being touched, squirted a deluge of fetid oily fluid from the stomach on the offenders. The nest of *D. chlororhynchus* was solitary, and the bird selected some sheltered corner, particularly the small drains that draw the water off the land into the ravines. 'Here,' continues Captain Carmichael, 'it runs up its nest to the height of ten or twelve inches, of a cylindrical form, with a small ditch around the base. A curious circumstance with regard to this bird is, that when irritated, the feathers of its cheeks are separated, so as to display a beautiful stripe of naked orange skin running from the corners of the mouth towards the back of the head. All these birds nourish their young by disgorging the contents of their stomach. They are never observed to carry any article of food in their bill: those matters indeed from which they derive the chief part of their sustenance,—the blubber of dead whales, seals, and sea-lions,—would melt away if carried in the bill to any distance. We could not help admiring the utter unconsciousness of danger displayed by them on our approach; they never showed the least disposition to move out of the way; even when kicked, or pulled off their nests, they made not the smallest show of resistance; but quietly returned to their post, or stood until we passed on. Their plumage is of the finest order, copious, and without the slightest stain. They find great difficulty in getting on wing, and must run twenty or thirty yards along the ground with expanded wings, before they can get fairly under-way. We had the curiosity to take one of them by the point of the wings, and fling it over the rock; yet, though it had several hundred feet of a clear fall, it never recovered itself, but dropped down like a stone. On this account, when not engaged with their young, they usually rest upon the edge of the precipice, from which they can launch at once into the air.'

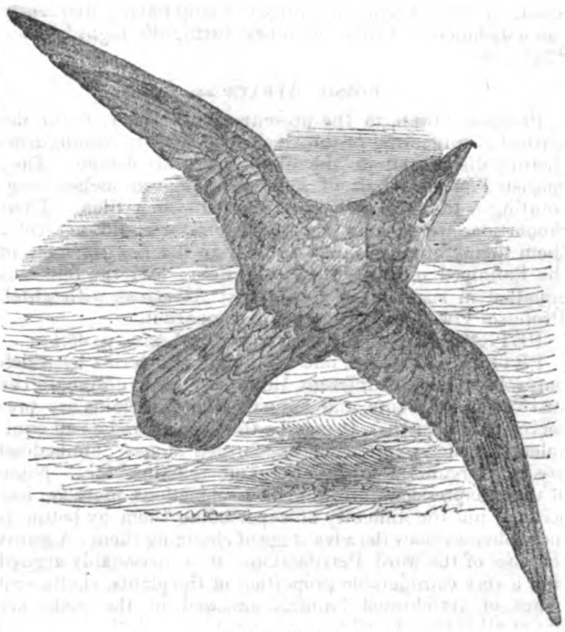
Captain Carmichael and his party, in a difficult part of their route, had to kick upwards of a dozen of them to the right and left before they could get on.

Prion. (Lacépède.)

This is the genus *Pachyptila* of Illiger.

Generic Character.—Bill strong, stout, wide, very much depressed, the upper mandible convex on its sides, terminated by a compressed hook; the edges furnished internally with cartilaginous lamellæ; the lower mandible very much depressed, formed of two arcs soldered at the point, and forming in their interval a guttural pouch; nostrils opening by two distinct orifices and disposed in the form of a short tube. A very small claw in place of a hind-toe. First *quill* longest.

The type of this genus is the *Blue Petrel* (*Procellaria vittata* and *cærulea*, Gm.) discovered by Forster. Many individuals were taken during the voyage of the *Coquille*, in 58° S. lat. The following is from M. Garnot's description of an individual of this species, which, in the form of its bill at least, appears to be leading the way towards the *Lamellibranchiate Palmipedes.* It is distinguished from the other Petrels by the disposition of its bill. The mandibles are hooked at their extremity; their base is very much widened. The edges of the upper mandible are directed a little outwards; they present within a projecting border striated transversely: the interval which separates them exhibits a small groove. The tongue is very thick and the mouth very dilatable. Total length, from the bill to the extremity of the tail, 11 inches (French). Length of the nasal tube 3 lines. Extent of wings 20 inches. Size a third larger than *Thalassidroma pelagica;* upper part of the body ashy blue or grey blue, deepest on the head and on the wings. A blackish band cuts across the wings and the lower part of the back near the origin of the tail. This portion is deepest in colour; the extremity of the tail has the same blackish deep blue tint; lower part of the body and wings white; above the tail a line of a blue tint; bill and eyes plumbeous blue; middle of the upper mandible and tube of the nostrils blackish. The middle tail-feathers are rather the longest, which gives the tail a rounded appearance. The same author gives an interesting detail of the anatomy of the bird.



Prion vittatus.

In a letter addressed by John Gould, Esq., corresponding member of the Zoological Society, dated Van Diemen's Land, May 10, 1839, and read on the 8th of October last, that distinguished ornithologist mentioned several interesting particulars relative to Oceanic birds observed by him upon his voyage. Immediately off the Land's End, Wilson's Storm Petrel (*Thalassidroma Wilsonii*) was seen in abundance, and continued to accompany the ship throughout the Bay. The little Storm Petrel (*Thalassidroma pelagica,* Selby) was also seen, but in far less numbers; both species disappeared on approaching the latitude of Madeira, their place there being occupied by another species, which Mr. Gould took to be *Thal. Bulweri.* This latitude was also favourable to the Shearwaters, *Puffinus cinereus* and *Puff. obscurus,* the former being there in great numbers. Mr. Gould crossed the equator on the 7th July, having been more than twenty days within the tropics, part of which time the vessel lay becalmed. This portion of the ocean's surface was also inhabited by Storm Petrels, but of a distinct species from any Mr. Gould had hitherto observed, and which he believes to be new to science. These birds, with now and then a solitary *Rhynchops* and Frigate Bird (*Tachypetes*), were all of the feathered race that he observed in these heated latitudes. On the 20th July, when the ship was in 26° S. lat., they were visited for the first time by the Cape Petrel (*Procellaria Capensis*): on the 23rd (lat. 31° 10′ S. long., 24° west) they were surrounded by the feathered race. Independently of an abundance of Cape Petrels, two other species and three kinds of Albatrosses were observed. The latter were *Diomedea exulans, D. Chlororhynchus,* and *D. fuliginosa.* A few days after this, they commenced running down their longitude, and from that time, until they reached the shores of Van Diemen's Land, several species of *Procellaridæ* accompanied the ship. Mr. Gould found, as he had every reason to expect, the Australian Seas inhabited by their own peculiar Storm Petrels (*Thalassidroma*), four distinct species of which he had already observed since leaving the Cape. 'From the westerly winds which prevail in the southern hemisphere,' adds Mr. Gould, 'between the latitudes 35° and 55°, I am induced to believe that a perpetual migration is carried on by several members of the oceanic family continually passing from west to east, and circumnavigating this portion of the globe. This remark more particularly refers to the Albatrosses, Prions, and other large kinds of Petrels; the same individuals of several of these species having been observed to follow our ship for some thousands of miles. Until I had ascertained that they were nocturnal, it was a matter of surprise to me how the birds which were seen around the vessel at nightfall were to be observed crossing our wake at day-break on the following morning, the ship having frequently run a distance of nearly 100 miles during the night.' (*Zool. Proc.*, 1839.)

Fossil Albatross.

Professor Owen, in the present month (May, 1840), described at a meeting of the Geological Society certain ornitholites discovered in the chalk near Maidstone. They consisted of the shaft of a humerus eleven inches long, wanting both ends, and two fragments of a tibia. Their proportions were such that the Professor could not refer them to any other group of birds than the *Longipennes* of the Palmiped order of Cuvier's system; and the humerus equalled in size that of the largest Albatross with which Professor Owen had been able to compare it.

PETRI'COLA. [Lithophagidæ, vol. xiv., p. 48.]

PETRIFACTIONS, one of the general terms by which naturalists have at different times sought to designate the vast variety of plants and animals whose remains are preserved in the earth. It may be thus considered as an equivalent for such expressions as 'formed stones,' 'imbedded fossils,' 'organised fossils,' 'organic remains,' &c. None of these expressions are free from objections more or less serious, but the difficulty of superseding them by better is more obvious than the advantage of changing them. Against the use of the word Petrifactions, it is reasonably argued that a very considerable proportion of the plants, shells, and bones of vertebrated animals enclosed in the rocks are not at all petrified; while, on the other hand, the process of lapidification has been found to have been perfectly performed on objects of comparatively recent date never imbedded in the earth, as the wood of a Roman aqueduct in Westphalia. Calcareous deposits from springs, which invest mosses, shells, and bones with a stony case, are often called petrifactions. [Organic Remains.]

PETROCINCLA. [Merulidæ, vol. xv., p. 122.]

Lieutenant-Colonel Sykes, in his 'Catalogue of Birds observed in the Dukhun' (Deccan), records a species under the name of *Petrocincla Pandoo*, and remarks that it differs from the *Solitary Thrush* of Europe (*Turdus Cyaneus*, Linn.) in its smaller size, slighter form, want of orange eyelids, and white tips to the feathers. *Pet. Pandoo* is found only in the dense woods of the Ghauts, and its flight is low and rapid. Colonel Sykes adds, that it appears to correspond with Var. A. of Dr. Latham's *Solitary Thrush*, vol. v., p. 47. *Petrocincla Maal* and *Petrocincla cinclorhyncha* are recorded by Colonel Sykes in the same catalogue. (*Zool. Proc.*, 1832.)

PETROICA. [Sylviadæ.]

PETRO'LEUM, a viscid variety of bitumen, which is found in many parts of Europe and America, but chiefly in Asia, flowing from beds associated with coal strata. As much as 400,000 hogsheads is said to be collected annually in the Birman empire. It is also abundant in Persia, and it is found, among other places, in the island of Barbadoes. It is sometimes used in medicine, and it is contained in the materia medica of the London Pharmacopœia, under the name of *Petroleum Barbudense*.

This substance has a dark reddish-brown colour; it is slightly translucent, and its odour is bituminous. The petroleum of Bechelbronn in the department of the *Bas Rhin* has been particularly examined by Boussingault: it is viscid, and has a very deep brown colour; it is known in the neighbourhood of the place in which it occurs by the name of *stone oil*, and is employed as a substitute for grease in diminishing the friction of machinery. It is totally and readily soluble in æther. When this petroleum is heated to the temperature of 212° in a retort, nothing whatever distils; it is evident therefore that it contains no naphtha. When however the heat is raised to nearly 450°, drops of an oily fluid come over, though very slowly; this oily body has a brown colour, and is very liquid; it is rendered pure by drying over chloride of calcium, and rectification. In obtaining this oil in the first instance the petroleum is mixed with water. *Petrolene* is the name given by Boussingault to this oil; its properties are, that it has a pale yellow colour, slight taste, and a bituminous smell. Its specific gravity is about 0·891. Even when cooled down to about 10° Fahr., it retains its fluidity. It stains paper like the volatile oils, boils at 536°, burns with a good deal of flame, but accompanied with much smoke. It is sparingly soluble in alcohol, but in larger quantity in æther. It yielded by analysis:—

Hydrogen	.	12·21
Carbon	.	87·04
		99·25

Dr. Thomson considers it to be constituted of

16 equivalents of hydrogen	= 16	.	12·5
20 equivalents of carbon	= 120	.	87·5
Equivalent	136		100·

Asphaltene is the solid portion of petroleum. Boussingault obtained it by treating petroleum with alcohol, which dissolves the greater part of the petroleum and leaves the asphaltene unacted upon; by the application of heat the whole of the more volatile constituent is expelled, and asphaltene, possessing the following properties, remains:—Its colour is black, and it has a great deal of lustre. It breaks with a conchoidal fracture, and is heavier than water. When heated to about 572°, it becomes soft and elastic. It burns, like the resins, without leaving any residue.

Dr. Thomson concludes, from the experiments of Boussingault, that asphaltene is composed of

15 equivalents of hydrogen	= 15	.	9·81
19 equivalents of carbon	= 114	.	74·51
3 equivalents of oxygen	= 24	.	15·68
Equivalent	153		100·

He is also of opinion that asphaltene is nothing more than petrolene combined with 3 equivalents of oxygen. It appears probable also that the petroleum of Bechelbronn is composed of

1 equivalent of petrolene	= 136	or	14·53
5 equivalents of asphaltene	= 765		85·47
Equivalent	901		100·

It is extremely probable that substances very differently constituted may be classed together under the general term of petroleum; for while Boussingault obtained a fluid carburetted hydrogen, which we have just described under the name of petrolene, from the petroleum of Bechelbronn, Drs. Christison and Reichenbach produced a solid carburetted hydrogen from the petroleum of Rangoon; the former called it *petroline*, and the latter *paraffin*. [Hydrogen, *Carburets of*.]

PETROMY'ZON, according to Linnæus, a genus of fishes, but now usually regarded as a family, called Petromyzidæ. These fishes constitute the section Cyclostomi of the 'Règne Animal,' and are distinguished by their imperfectly developed skeleton, their want of pectoral and ventral fins, combined with an eel-like form of body. The mouth is circular, consisting of a cartilaginous ring which supports the lips, this ring being formed by the soldering together of the palatine and mandibular bones. The branchiæ, instead of being pectinated, as in most other fishes, are purse-shaped; they are moreover fixed, and open externally by several apertures.

From the very imperfect state of their skeleton (which consists chiefly of a ribless series of cartilaginous rings), and some other peculiarities in their structure, these fishes may be regarded as the lowest of the vertebrate animals. The genus Petromyzon, as now restricted, contains the fishes commonly known as Lampreys. These eel-like fishes are of a cylindrical form, compressed towards the tail, and destitute of scales: they have seven branchial openings on each side, and a small opening connected with these on the upper surface of the head, situated nearly between the eyes the mouth, or maxillary ring, is armed with strong teeth, and on the inner disk there are smaller rasp-like tubercles: there are moreover two longitudinal series of small teeth on the tongue, which is so formed that, by its movement in the mouth, it acts as a piston, and enables the animal to attach itself by suction to any foreign body.

The Lamprey (*Petromyzon marinus*, Linn.) is usually about two feet in length, of a yellowish colour marbled with brown; its two dorsal fins are distinctly separated, the second one joins with the tail fin, as well as a small strip which represents the anal fin.

'The Lampreys, like the Sharks and Rays,' says Mr. Yarrell, 'have no swimming bladder; and being also without pectoral fins, are usually seen near the bottom. To save themselves from the constant muscular exertion which is necessary to prevent them from being carried along with the current of the water, they attach themselves by the mouth to stones or rocks, and were in consequence called

Petromyzon, or Stone-sucker; while the circular form of the mouth induced the name Cyclostomes, or round-mouthed fishes, which was bestowed upon them by M. Duméril.'

The Lamprey is highly esteemed for the table, and is consequently much sought after in the various rivers in which it is found. According to the author just mentioned, it is rather common during the spring and summer season in some of the rivers on the southern coast of England, particularly the Severn; and is found in smaller numbers in several of the rivers of Scotland and Ireland about the same period of the year. 'In Scotland,' Sir W. Jardine says, 'they ascend our rivers to breed about the end of June, and remain until the beginning of August. They are not furnished with any elongation of the jaw, afforded to most of our fresh-water fishes, to form the receiving furrows at this important season; but the want is supplied by their sucker-like mouth, by which they individually remove each stone. Their power is immense. Stones of very large size are transported, and a large furrow is soon formed. The *P. marinus* remains in pairs, two on each spawning-place; and while there employed, retain themselves affixed by the mouth to a large stone.'*

The Lamprey feeds upon soft animal substances, and often attacks fishes of large size; and fixing itself upon them, it eats the flesh by means of its rasp-like teeth.

Two other species of Lamprey, the *Petromyzon fluviatilis* and *P. planeri*, are found in England. The first, called the Lampern, or River Lamprey, is common in many of the English rivers. 'Formerly,' says the author of the 'History of British Fishes,' 'the Lampern was considered a fish of considerable importance. It was taken in great quantities in the Thames, from Battersea Reach to Taplow Mills, and was sold to the Dutch as bait for the turbot, cod, and other fisheries. Four hundred thousand have been sold in one season for this purpose, at the rate of forty shillings per thousand. From five pounds to eight pounds the thousand have been given; but a comparative scarcity of late years, and consequent increase of price, has obliged the line fishermen to adopt other substances for bait. Formerly the Thames alone supplied from one million to twelve hundred thousand lamperns annually. They are very tenacious of life, and the Dutch fishermen managed to keep them alive at sea for many weeks.'

This fish is usually about one foot in length, and coloured like the common eel: the lip surrounding the mouth has a continuous row of small points; there are two large teeth on the maxillary ring; and the dorsal fins, which are elongated, are distinctly separated. The third species, called the fringed-lipped lampern (*P. Planeri*), has the two dorsal fins placed close together; it is of a shorter and stouter form; and it may moreover be distinguished from the common lampern by its lips being furnished with numerous papillæ, forming a thickly-set fringe.

The fringed-lipped lampern appears to be usually smaller than the common species; it is found in the Tweed, and in some of the streams in the southern parts of Great Britain, but appears to be comparatively scarce.

The second genus of Petromyzidæ is the Mixine of Linnæus. In this genus the maxillary ring is altogether membranous, and only furnished with a single tooth on its upper part; the series of teeth on the tongue are strong, and arranged in two rows on each side, so that the jaws of these fishes appear to be lateral, like those of insects or the Nereides, a circumstance which induced Linnæus to place them in the class Vermes. The mouth is circular, and furnished with eight cirri; in its upper margin is a spiracle which communicates with its interior. The body is cylindrical, and furnished with a fin which surrounds the tail. The skeleton is here reduced to a mere cartilaginous tube. These singular fishes pour out such an abundance of mucus through the pores of their lateral line, that the water in the vases in which they are kept seems to be converted into a jelly. They attack and pierce other fishes like the lampreys. A certain Myxine found in the South Seas (Petromyzon cirrhatus of Forster), owing to its possessing seven branchial apertures like the lampreys, has furnished the type of Duméril's subgenus *Heptatremus*. In the subgenus *Gastrobranchus* (Block) the intervals of the branchiæ, instead of having separate openings, communicate with a common canal on each side, each of which terminates in a distinct hole situated under the heart. To this section belongs the Myxine, Glutinous Hag, or Borer of English authors, the *Mixine glutinosa* of Linnæus, and *Gastrobranchus cæcus* of modern authors. [Myxine.]

The next genus of this section (*Ammocetes*, of Duméril) has the same general form as the lampreys, and the branchial orifices are the same; but the mouth is semicircular, and the lip only covers the upper portion; hence the fishes have not the power of fixing themselves, like the true lampreys. They have no teeth, but the mouth is furnished with a series of fleshy tubercles.

The fish found in our streams, and known by the names Pride, Sandpride, and Mud Lamprey (*Ammocetes branchialis*, Cuv.), affords an example of this genus. This little fish, which is seldom more than six or seven inches in length, and about the thickness of a quill, lives chiefly in the mud at the bottom of fresh-water streams, and is said to be much preyed upon by eels.

The last division of this family is the genus *Amphioxus* of Yarrell, and this contains but one species, a most extraordinary little fish, which, it appears, was first described by Pallas, under the name of *Limax lanceolatus*, but had not been seen since his time till the subject of Mr. Yarrell's description was discovered by Mr. Couch on the shore near Polperro.

The *Amphioxus lanceolatus*, or *Lancelet*, is rather more than one inch in length, of a compressed form, and pointed at both extremities, but most so at the tail, and of a pale yellowish colour. 'The head is pointed,' says Mr. Yarrell, 'without any trace of eyes; the nose rather produced; the mouth on the under edge, in shape an elongated fissure, the sides of which are flexible; from the inner margin extend various slender filaments, regularly disposed, which cross and intermingle with those of the opposite side: along the sides of the body the muscles are arranged in regular order, diverging from a central line, one series passing obliquely upward and backward, the other series as obliquely downward and backward: the anal aperture is situated one-fourth the whole length of the fish in advance of the end of the tail; the tail itself is pointed: from the nose to the end of the tail a delicate membranous dorsal fin extends the whole length of the back, supported by very numerous and minute soft rays; the surface of the body is smooth. The body is supported internally throughout its length by a flexible cartilaginous column, from which the numerous muscles diverge.'

PETRO'NIUS A'RBITER is the name of the author, or supposed author, of a kind of novel in Latin, of which we have only fragments, descriptive of the licentious manners of the Romans under the empire. Several young debauchees, one of whom is the chief narrator, are represented strolling about Campania, and then proceeding by sea to Croton; they meet with numerous adventures with men and women of various ranks, but all as profligate as themselves. Both the descriptions and the dialogue are extremely obscene, and serve to corroborate the testimony of Juvenal and other writers as to the excessive depravity of morals under the empire. As a picture of manners, the work is not without its value, though it is totally unfit for general readers. The style is fluent and the language is considered classical. The episode entitled 'Trimalcion's Feast' is a curious description of a banquet given by a pompous wealthy freedman. The narrative is intermixed with verses and fragments of poems, one of which refers to the civil wars of Cæsar, and contains a very strong invective against the corruption of Roman manners. The prose narrative has been supposed by some to be a satire on Nero and his court, but this supposition does not seem to rest on sufficient evidence. Indeed the age of the work is not ascertained, and some date it as late as the time of the Antonines. (Ignarra, *De Palæstra Neapolitana.*) Caius Petronius, a man of high rank, is mentioned by Tacitus (*Annal.*, xvi. 18, 19) as being for a time a favourite of Nero, and minister of his pleasures, 'arbiter elegantiæ,' which may be translated umpire of fashion and master of the ceremonies. Being afterwards discarded by Nero through the jealousy of Tigellinus, and expecting his sentence of death, he anticipated it by causing his veins to be opened in the bath, and allowing himself to die gradually while conversing with his friends on light subjects. He is stated during this interval to have written an account of Nero's secret debaucheries, which he sent to the emperor. Whether the fragment which we have was part of this work, or whether it was written by another Petronius, has been much disputed. The best edition of

---

* 'History of British Fishes,' vol. ii.

Petronius is that by P. Burmann, 2 vols. 4to. 1743, in which all the various opinions on the work and its author are given.

PETRO'PHILA. [Merulidæ, vol. xv., p. 122.]

PETRO'SILEX. This name has probably been given to two different minerals, viz. compact quartz and compact felspar; the latter has also been termed fusible petrosilex. [Felspar.]

PETROSELI'NUM. [Parsley.]

PETROV, VASSILI PETROVITCH, was the son of a clergyman at Moscow, where he was born in 1736. While in the Zaikonospasskoi school in that city, he distinguished himself by his aptitude for antient and modern languages, and also by a natural eloquence, and fluency of ideas and words. Whether he exhibited much precocity of talent in poetry is less certain, for it was not until his twenty-seventh year that he composed the ode on Catherine's coronation, which obtained for him the notice and protection of the empress herself, and of many of the nobles at her court, and especially of Prince Potemkin. For a time he held the appointment of reader to the empress, but at his pressing solicitations obtained leave to travel. He visited England and several other countries, from the year 1772 to 1774. After his return he was made imperial librarian, which situation however he was obliged to give up in 1780, on account of ill health, and he retired with a pension to a village in the government of Orlov. Here he divided his time between literary and agricultural pursuits, visiting Moscow every winter for the purpose of availing himself of its libraries. So diligent were his habits of study, that at the age of sixty he began to learn the modern Greek language. He died December 4-16, 1799, in his 64th year.

A complete edition of his original works appeared in 3 vols. 8vo., 1811; besides which there is a translation by him of Virgil's 'Æneid,' in 2 vols., 1781-6. His poems consist chiefly of odes and epistles, and although they have now lost much of their first interest, having been written upon particular occasions, many of the former are stamped by high poetical beauty and merit, by vigour and originality of ideas, and by energy of expression; but it must at the same time be admitted that his versification is occasionally harsh, and his diction not sufficiently polished. It should be borne in mind however, that at the time Petrov began to write, the language itself had not received that refinement which it now possesses, and he certainly did much for his native literature. Merzliakov calls him the 'philosopher bard,' and says that he 'abounds in transcendent imagery, traced with a pen of fire.'

PETRUS DE ABA'NO. [Abano.]

PETRUS HISPA'NUS, a native of Lisbon, son of a physician named Julian, became eminent for his acquaintance with the sciences, particularly that of medicine, the practice of which he followed for some time with great reputation. He afterwards entered holy orders, and advanced by degrees to high preferment. After being archbishop of Braga in Portugal (*Bracara Augusta*), he was made cardinal by Gregory X., A.D. 1273; and on the death of Adrian V. he was elected to the pontifical dignity, Sept. 13, 1276. He took the name of John, and styled himself on his seal Joannes XX.; but in his epitaph at Viterbo he is called Joannes XXI.[*] One of the first acts of his pontificate was to confirm Adrian's revocation of the famous constitution of Gregory X. (enacted at the council of Lyon, 1274), which ordered that the cardinals should be strictly shut up in the conclave during their election of a new pope. He did all in his power to assist the Christians in the East, and sent legates to the different princes of Europe to persuade them to engage in a fresh crusade against the Saracens. He died at Viterbo, about eight months after his elevation to the holy see, May 17, 1277, of the injuries occasioned by the falling of the roof of his bed-chamber. He was a very learned man himself, and a great patron of learning in others; but he does not seem to have been eminent for piety and holiness of life. He wrote several works on medicine, logic, &c., of which the greater part are still unpublished. A list of their titles may be seen in Ciaconius, 'Vitæ Pontiff. et Cardd.,' tom. ii., p. 213. The most celebrated is a short medical treatise entitled 'Thesaurus Pauperum, seu de Medendis Corporis Humani Morbis per Euporista,' of which there are several editions. It was first printed 1476, Antwerp, fol.; the last edition was published 1577, Paris, 16mo., with a sort of continuation by J. Liebault, entitled 'Thesaurus Sanitatis, Paratu facilis.' A Spanish translation was published at Valladolid, 1672; and an English one by Humphrey Lloyd, London, 1585, 8vo. It consists of 90 chapters, containing a short account of a great number of diseases, and at the end of each is given a quantity of medical formulæ taken from the works of the Greek, Latin, and Arabic physicians, to which is now and then added the word *expertum*. It is not of much value, and contains a great deal that is foolish and superstitious. In the collected edition of the works of Isaac (commonly called 'Isaac Israelita'), Lugd., 1515, fol., there are three treatises by Petrus Hispanus: one entitled 'Commentarium singulare super Librum Dietarum Universalium Isaac, fol. xi.-ciii.; the second a commentary on Isaac's work 'De Diætis Particularibus,' fol. ciii.-clvi.; and the third on his work 'De Urinis,' fol. clvi.-cciii. There is a tract by J. T. Köhler, which the writer of this article has not been able to consult, entitled 'Vollständige Nachricht von Pabst Johann XXI., welcher unter dem Namen Petrus Hispanus als ein Arzt und Weltweiser berühmt ist,' Götting., 1760, 4to. (Ciacon., *Vitæ Pontiff. et Cardd.*; Haller, *Biblioth. Medic. Pract.*)

PETTY, SIR WILLIAM, an eminent political economist, was born May 16th, 1623, at Romsey in Hampshire, where his father carried on the business of a clothier. After remaining until the age of fifteen at the grammar-school of his native place, he went to pursue his studies at Caen in Normandy. On his return, he is said to have entered the navy, but the time which he spent in this service must have been short, as in 1643 he again visited the Continent, and spent three years in France and the Low Countries. During this interval he studied medicine and anatomy. In 1648 he published a small work, addressed to Mr. Samuel Hartlib, recommending the extension of education to objects connected more immediately with the daily business of life. Soon afterwards he went to Oxford, where the visitors appointed by the parliament had ejected the royalists, and employed himself in giving instruction in anatomy and chemistry; in 1649 he was created doctor of physic, and elected a fellow of Brazen-nose College. In 1650 he was appointed to the anatomical professorship in the university. He was an active member of a society instituted in Oxford for the cultivation of natural science, and which was the immediate precursor of the Royal Society. When the Royal Society was established, he was one of the council. In 1652 the period of his good fortune commenced by his appointment as physician to the army in Ireland. In 1654 he was employed in that country in the survey of forfeited estates, a work which he performed with great ability. He was subsequently engaged as a commissioner in dividing these lands amongst the officers and soldiers of Cromwell's army, when, besides the land allotted to him, he made advantageous purchases. He also acted as secretary to Henry Cromwell, lord-lieutenant of Ireland. He appears however to have been well received by Charles II. at the Restoration, and in 1661 was knighted. Sir William Petty died at his house in Westminster, December 16th, 1687, and was buried in the church of his native town, where a plain stone marks his grave, with the simple inscription—'Here lyes Sir William Petty.' His last will contains the following profession of his religious opinions:—'I die in the profession of that faith and in the practice of such worship as I find established by the laws of my country; not being able to believe what I myself please, nor to worship God better than by doing as I would be done unto, and observing the laws of my country, and expressing my love and honour of Almighty God by such signs and tokens as are understood to be such by the people with whom I live, God knowing my heart even without any at all.' The widow of Sir William Petty was created Baroness Shelburne. He left two sons and a daughter. The eldest son succeeded to the title, but dying without issue, it was revived in Henry, the second son, great-uncle of the first marquis of Lansdowne.

Sir William Petty was the author of several scientific works and inventions, and various papers on mathematical and chemical subjects in the 'Philosophical Transactions;' but he is far better known in the present day as a writer upon trade and commerce and political arithmetic. Notwithstanding the great variety of his pursuits, he had emancipated himself from nearly all the errors and prejudices of

[*] The confusion about the popes of the name of John is partly occasioned by the fictitious Pope Joan being reckoned as John VIII. This however will not entirely account for it, as Petrus Hispanus is sometimes called John XIX., and sometimes John XXII. (See Genebrard, *Chronograph.*, lib. iv., Paris, 1580, fol.)

his contemporaries. The 'Political Anatomy of Ireland,' one of his best works, contains valuable information respecting the state of Ireland in the latter part of the seventeenth century, and gives the first authentic account of the population. Sir William Petty clearly foresaw the advantages of a union of Great Britain and Ireland, and of a free commercial intercourse between the two countries. The survey of Ireland which he made during the Protectorate continues, after the lapse of nearly two centuries, to be a work of reference in courts of law in matters relating to landed property. His treatise on 'Taxes and Contributions,' published in 1667, contains in general sound views on the subjects of finance and revenue; and in this work the doctrine was first clearly stated, though only in an incidental manner, that the labour required for the production of commodities alone determines their value. The 'Political Arithmetic' treats chiefly on the subject of population, particularly with reference to London. His predictions concerning the growth of the metropolis are amusing, and do not exhibit his usual acuteness. At the time when he wrote, he calculated that the population of London doubled itself in 40 years, and that of England in 360 years; and hence he concluded that the population must reach a stationary point before 1840, at which period it would be ten millions for the metropolis, and also ten millions for the rest of England. 'Wherefore (he remarks) it is certain and necessary that the growth of the city must stop before the said year 1840.' Since 1700 however London has increased 122 per cent., and England 154 per cent. Sir William Petty published his 'Quantulumcunque' (a treatise on money) in 1682, at which period the question of the monetary circulation was of great interest. He recommended that one metal should be made the uniform measure of value, in which view he was supported by Locke: Sir Isaac Newton proposed both the precious metals. The subject is treated with great ability, but the error of his time is perceptible in some of his arguments, which show that he entertained the false notion that there was something about gold and silver distinguishing them as articles of commerce from all other commodities. In this work he condemned laws regulating the rate of interest, observing that there might as well be laws to regulate the rate of exchange; and he exposed the prevailing fallacy that a country may be drained of cash by an unfavourable balance of trade. A list of the remainder of Sir William Petty's works is given in Watt's 'Bibliotheca Britannica.'

PETUNTZE, the Chinese name for a white earth used with kaolin in the manufacture of porcelain: it is stated that while the former [KAOLIN] is derived from the decomposition of the felspar of granitic rocks, the latter, or petuntze, is the same mineral which has not suffered decomposition, and that on account of its fusibility it is employed in glazing the porcelain.

PETWORTH. [SUSSEX.]

PEUCE'DANIN, a peculiar principle obtained from the *peucedanum officinale*, or sea sulphur-wort. By treatment with alcohol a solution was obtained which deposited crystals, to which the name of *peucedanin* was given by Schlatter. These crystals are colourless, acicular, transparent, inodorous, and insipid; but when dissolved in alcohol, their taste is very aromatic; they melt at 140° without losing weight; and when the heat is increased, the fluid mass assumes a greenish and afterwards a greyish-white tint: they are insoluble in cold water, and melt in it when boiling without dissolving; in cold alcohol they dissolve but sparingly, but when it is heated to 140°, they dissolve in it readily, and the solution is decomposed by water, and also by solution of chloride of tin, sulphate of copper, and acetate of lead, but not by sulphate of iron. It does not appear to possess either acid or alkaline properties. It yielded by analysis:—

2 equivalents of hydrogen	2	or	5·8
4 equivalents of carbon	24		70·6
1 equivalent of oxygen	8		23·6
Equivalents	34		100·

PEUTINGERIAN TABLE is the name given to a map of the roads of the antient Roman world, which is on parchment, and was found in a library at Speyer in the fifteenth century. It was bequeathed by the proprietor Conrad Celtes to his friend Conrad Peutinger, a learned man of Augsburg, who began to prepare a copy of it for publication, but died in 1547, before he could effect his purpose. Mark Velter however copied it on a scale less than one-half of its original size, and sent his copy to Ortelius, who forwarded it to Muretus, who published it in 1598. This reduced copy has been inserted in the Ptolemy of Bertius, in Horn's 'Orbis Delineatio,' and in Bergier's 'Histoire des grands Chemins de l'Empire Romain.' The original map remained at Augsburg, in the possession of Peutinger's descendants, till 1714, when it was purchased by a bookseller, and sold by him to Prince Eugene, who gave it to the imperial library of Vienna. An exact copy of it was made by F. C. von Scheyb, at Vienna, with an introduction and index, and dedicated to the empress Maria Theresa; 'Tabula Itineraria Peutingeriana, quæ in Augusta Bibliotheca Vindobonensi nunc servatur, adcurate exscripta à Fr. Christoph. De Scheyb, cum Indice,' fol., Vienna, 1753. The map is 21 feet in length, and about one foot wide. The author, whoever he was, did not intend to draw a proper geographical map, with the relative position of countries [MAP; AGATHODÆMON], but merely to collect all the great roads of the empire into a long narrow strip, marking the stations upon each, and the distances between the stations, for the information of travellers and chiefly of military and civil officers. In consequence of this arrangement, the great lines of roads are represented as nearly parallel, and most of the great rivers are also made to run in the same direction, from west to east or east to west, which was that of the greatest length of the Roman empire. But the northern and southern boundaries of the empire are brought into close approximation to each other, without any regard to the latitude. For the same reason, the Mediterranean, Adriatic, Ægean, and Euxine seas are all compressed in breadth into the shape of long channels, the peninsula of Italy appears to run straight from west to east, and the islands, such as Sicily, have undergone a like compression of form. The towns on the roads are marked by small houses; some, being worthy of particular notice, are designated by square buildings like barracks; and some more important towns and military stations, such as Aquileia, Ravenna, &c., are distinguished by walls and towers. Rome is distinguished by a circle with a crowned figure seated in the middle, and the port of Trajan is conspicuously sketched near the right bank of the Tiber, at the mouth of the river. Constantinople is marked by a circle and a figure, which however is not crowned. Antioch is the only other city which is also distinguished by a circle and a figure, in which last Mannert thinks that he recognises the Virgin Mary, which he believes to be an interpolation of some copyist of the middle ages, who had before him an older map of the time of the Pagan emperors. (Mannert's 'Introduction' to his new edition of Peutinger's Table, folio, Leipzig, 1824.) That the original map was drawn while the old religion of the empire was still dominant, seems proved by the heathen temples which are marked upon it, whilst there is no Christian name, with the exception of St. Peter's at Rome, which is probably also an interpolation of the copyist, who has taken care to notice the desert between the Red Sea and Palestine, as being that 'in which the children of Israel wandered for forty years,' as well as Mount Sinai, where 'they received the law.' Several other particulars on the map seem to fix the date of its original construction to about the time of Alexander Severus, after the Persians had overthrown the Parthian dominion, A.D. 226. The Persian empire is marked in its full extent and written in large capitals, whilst Parthia is indicated by smaller characters as a province. Palmyra is marked as an important place, with roads leading to it through the desert, which would seem to refer to an epoch previous to its destruction by Aurelian. Edessa in Macedonia is marked under that name, whilst in the Antonine Itinerary it is called Diocletianopolis. This and other evidence collected by Mannert indicate at all events an epoch between the reign of Alexander Severus and the end of the third century, making allowance for the interpolations of subsequent copyists.

The Peutingerian Table does not always agree with the Antonine Itinerary; several stations and towns which are in the one are not in the other; the distances between the stations marked on both sometimes disagree; besides which, in consequence of the form of the map, several roads which are distinct on the Itinerary are placed on the map consecutively, as if they all formed one line; whilst others, which are single roads on the Itinerary, are cut into two or three in the map. However the Itinerary is still of great use in explaining the map, and the two together are among the most valuable antient works on geography which have come down to us.

The map extends to the right, or east, as far as the mouths of the Ganges. Roads are traced through India to several emporia, or places of trade, on the coast. To the west the map ends abruptly on the borders of Spain, including farther north only the eastern part of Britain. It is evident, as Mannert maintains, that one leaf is wanting, and it has perhaps been lost.

PEW. A pew is defined by Dr. Johnson to be 'a seat enclosed in a church.' Sittings enclosed in a church would perhaps be a more correct description, inasmuch as a pew contains several seats; and it not unfrequently happens that different families have the right of sitting in the same pew. The word pew is scarcely to be met with in authors upon ecclesiastical law, who almost invariably use the expression 'church seat.'

There were no pews in churches until about the period of the Reformation, prior to which the seats were moveable, such as chairs and benches, as we see at this time in the Roman Catholic churches on the Continent. Before that time no cases are to be found of claims to pews, although in the common-law books two or three claims are mentioned to seats in a church or particular parts of a seat, which were probably moveable benches or forms.

'By the general law and of common right,' Sir John Nicholl observed (in Fuller *v.* Lane, 2 *Add. Eccl. Rep.*, 425), 'all the pews in a parish church are the common property of the parish; they are for the use *in common* of the parishioners, who are all entitled to be seated orderly and conveniently so as best to provide for the accommodation of all.' The right of appointing what persons shall sit in each seat belongs to the ordinary (3 *Inst.*, 202); and the churchwardens, who are the officers of the ordinary, are to place the parishioners according to their rank and station; but they are subject to his control if any complaint should be made against them.' (Pettman *v.* Bridger, 1 *Phill.*, 323.) A parishioner has a right to a seat in the church without any payment for it, and if he has cause of complaint in this respect against the churchwardens, he may cite them in the ecclesiastical court to show cause why they have not seated him properly; and if there be persons occupying pews who are not inhabitants in the parish, they ought to be displaced in order to make room for him. This general right however of the churchwardens as the officers of the ordinary is subject to certain exceptions, for private rights to pews may be sustained upon the ground of a faculty, or of prescription, which presumes a faculty.

The right by faculty arises where the ordinary or his predecessor has granted a licence or faculty appropriating certain pews to individuals. Faculties have varied in their form; sometimes the appropriation has been to a person and his family 'so long as they continue inhabitants of a certain house in the parish:' the more modern form is to a man and his family 'so long as they continue inhabitants of the parish' generally. The first of these is perhaps the least exceptionable form. (Sir J. Nicholl, 2 *Add.*, 426.)

Where a faculty exists, the ordinary has parted with his right, and therefore cannot again interfere: it has however been laid down in the ecclesiastical court that where a party claiming by faculty ceases to be a parishioner, his right is determined. Sir John Nicholl states, 'Whenever the occupant of a pew in the *body* of the church ceases to be a parishioner, his right to the pew, howsoever founded, and how valid soever during his continuance in the parish, at once ceases.' (Fuller *v.* Lane, 2 *Add.*, 427.) The same doctrine has been sanctioned by the Court of King's Bench. (Byerley *v.* Windus, 5 *Barn. and Cress.*, 18.) But in a case in the Court of Exchequer, chief-baron Macdonald was of a different opinion. The question there was whether there could be in law a prescription for a person living out of the parish to have a pew in the *body* of the church, and it was held that there might (Lousley *v.* Hayward, 1 *Y. and I.*, 583). As prescription presumes a faculty, these opinions seem to be at variance. Where a claim to a pew is made by prescription as annexed to a house, the question must be tried at law. The courts of common law in such cases exercise jurisdiction on the ground of the pew being an easement to the house (Mainwaring *v.* Giles, 5 *Barn. and Ald.*, 361); and if the ecclesiastical courts proceed to try such prescription, a prohibition would issue. In order to support a claim by prescription, *occupancy* must be proved, and also *repair* of the pew by the party, if any has been required; the onus and beneficium going together. (Pettman *v.* Bridger, 1 *Phill.*, 325; Rogers *v.* Brooks, 1 *T. R.*, 431; Griffith *v.* Matthews, 5 *T. R.*, 297.) The above observations apply to pews in the *body* of the church. With respect to seats in the chancel, it is stated in the Report of the Ecclesiastical Commission, page 49, 'the law has not been settled with equal certainty, and great inconvenience has been experienced from the doubts continued to be entertained. Some are of opinion that the churchwardens have no authority over pews in the chancel. Again, it has been said that the rector, whether spiritual or lay, has in the first instance at least a right to dispose of the seats; claims have also been set up on behalf of the vicar; the extent of the ordinary's authority to remedy any undue arrangement with regard to such pews has been questioned.' (Gibson, 226; 3 *Inst.*, 202; 1 Brown and Goul., *Rep.*, 4; Griffith *v.* Matthews, 5 *T. R.*, 298; Clifford *v.* Wicks, 1 *B. and Ad.*, 498; Morgan *v.* Curtis, 3 *Man. and Ryl.*, 389; Rich *v.* Bushnell, 4 Hagg., *Ecc. Rep.*, 164.)

With regard to aisles or isles (wings) in a church, different considerations apply. The whole isle or particular seats in it may be claimed as appurtenant to an antient mansion or dwelling-house, for the use of the occupiers of which the aisle is presumed to have been originally built. In order to complete this exclusive right it is necessary that it should have existed immemorially, and that the owners of the mansion in respect of which it is claimed should from time to time have borne the expense of repairing that which they claim as having been set up by their predecessors. (3 *Inst.*, 202.)

The purchasing or renting of pews in churches is contrary to the general ecclesiastical law. (Walter *v.* Gunner and Drury, 1 Hagg., *Consist. Rep.*, 314, and the cases referred to in the note, p. 318; Hawkins and Coleman *v.* Compeigne, 3 *Phill.*, 16.)

Pew-rents, under the church-building acts, are exceptions to the general law; and where rents are taken in populous places, they are sanctioned by special acts of parliament. Pew-rents in private unconsecrated chapels do not fall under the same principle, such chapels being private property.

PEWTER, a compound metal extensively employed, especially in the manufacture of those drinking-vessels called *pewter pots.* The finest pewter is said to consist of 12 parts of tin, 1 part of antimony, and a very little copper; while common pewter consists of about 80 parts of tin and 20 of lead. Pewter was formerly much more employed than at present, especially in the manufacture of plates and dishes.

PEYER, JEAN CONRAD, was born at Schaffhausen in 1653. He studied medicine at Basle and at Paris, and having taken the degree of doctor of medicine at the former university, returned to practise at his native town. He held there successively the professorships of eloquence, of logic, and of the physical sciences; but his present reputation is derived chiefly from his having first clearly described the little bodies which are scattered in patches along the end of the small intestines, and which are therefore commonly called Peyer's glands. He died in 1712. Besides his work on the intestinal glands, Peyer wrote numerous detached papers on morbid anatomy, of which he was one of the most assiduous of the early cultivators, and a few on practical medicine and comparative anatomy.

PE'ZE'NAS, a town in France, in the department of Hérault, on a cross-road from Aix to Perpignan, 39 miles from Montpellier, the capital of the department. Pézénas was known to the Romans by the name Piscenae; and is mentioned by Pliny (*Hist. Nat.*, lib. viii., c. 48) as producing in the neighbourhood wool which resembled hair rather than wool. In the middle ages it was the capital of a county. The town is pleasantly situated on the Peyne, a little stream which falls into the Hérault on its right bank, just below Pézénas. It has some tolerably good houses, and a handsome theatre. The population in 1831 was 7481 for the town, or 7847 for the whole commune. The townsmen manufacture blankets and coverlets, serges and other woollen stuffs, linens, cotton-yarn, thrown silk, hats, brandy, distilled waters, syrup of sugar and grapes, and chemical products. There are some dye-houses and tan-yards. Considerable trade is carried on in wines (of which the neighbourhood produces some of excellent quality), wheat, oats, seeds, red tartar, dyeing herbs, dried fruits, capers, olives, oil, cotton, wool, and woollen cloths. There is a considerable weekly market, and there are three yearly fairs. The neighbouring hills are covered with vines and almond and olive trees, and there is near the town an old castle built by the Constable Montmorency [MONTMORENCY], to whose family the county of Pézénas at one time belonged. There are a high school, a subordinate court of justice, and an Exchange.

PEZO'PORUS. [PSITTACIDÆ.]

PFEFFEL, GOTTLIEB CONRAD, a German writer of classic reputation in that branch of literature which comprises the tale, the fable, and the epistle, was born June 28th, 1736, at Colmar, where his father held an appointment in the office for foreign affairs. His parent dying in 1738, Pfeffel was left entirely to the charge of an excellent mother. At the age of fifteen he was sent to the university of Halle for the purpose of applying himself to the study of jurisprudence; but this plan was entirely frustrated by a severe attack of ophthalmia, which terminated in his total blindness at the age of twenty-one. He married about two years after this misfortune, and at a later period (1773) obtained permission to establish at Colmar a seminary for the education of Protestant youths, in conducting which he had an able colleague in his friend Hofrath Lerse. Among his pupils, who were chiefly the sons of Swiss families, were many who afterwards distinguished themselves. The changes produced by the French revolution however caused this school, which bore the title of a military one, to be broken up, and Pfeffel henceforth applied himself entirely to those literary occupations which, notwithstanding his blindness, he had before pursued at intervals. In 1803 he was made president of the Evangelical Consistory at Colmar, then recently established. He died May 1st, 1809, just after the publication of the ninth volume of his 'Poetischen Versuche.'

His poems generally display shrewdness and humour, together with a strong vein of moral and religious feeling; but his peculiar power shows itself most in his fables, which have frequently an epigrammatic energy and a piquant turn of expression that render the moral couched in them additionally striking and effective. Besides these and his tales, his other productions consist chiefly of poetical epistles, epigrams, ballads, and lyrical pieces. In addition to these original compositions, he translated a great many dramatic pieces from the French, which he published in five separate volumes or collections, from 1765 to 1774. These were indeed rather free versions than literal translations of the originals; for he did not scruple to retrench on the one hand what he considered their prolixities, and on the other to expand those parts of the dialogue which furnished hints for the purpose. His own dramatic attempts were less successful, since notwithstanding the skill shown in the arrangement of their plan, and the merit of many of their detached scenes, they were deficient in sustained interest and effect.

PFORZHEIM, the most important manufacturing town in the grand-duchy of Baden, is situated in 48° 55′ N. lat. and 8° 48′ E. long., in the circle of the Middle Rhine, at the entrance of the Black Forest, and on the navigable river Ens, near its junction with the Nagold and Wurm. It is surrounded with a wall and moat, and consists of the town and three suburbs. There are four churches and an antient palace, the church of which contains a handsome monument to the late Duke Charles Frederick. Among the public institutions are a convent for noble ladies, an hospital, an infirmary, an orphan-house, an asylum for the deaf and dumb, &c. The population of the town and suburbs is above 6500. The manufacture of trinkets employs above 1000 workmen; the value of the articles manufactured by them (in which no gold under 14 carats must be used) is 100,000*l.* sterling per annum. The manufactures of watches, superfine cloth and kerseymere, leather, hardware, and iron-wire are flourishing. There are also an iron-foundry, which furnishes annually 5000 cwt. of bar-iron, a copper-foundry, a manufactory of chemicals, many establishments for dyeing Turkish-red, and extensive bleaching-grounds. Pforzheim has a very great trade in timber from the neighbouring forests of Hagenschiess, which is floated down the Neckar and the Rhine to Holland. The trade in corn, oil, wine, and cattle is not inconsiderable, for which the situation of the town, on the high road from France to the south of Germany, is very favourable. The inhabitants have been always distinguished for their bravery and devoted attachment to their princes. Four hundred citizens, commanded by their burgomaster Deimling, formed the body-guard of the brave margrave George Frederick, in the battle of Wimpfen, May 6, 1622, in which, with 20,000 men, he engaged the far superior Imperial army commanded by Tilly. Victory already inclined to his side, when the powder-waggons were blown up, and scattered destruction among his troops. Flight was the only resource, which the Margrave, at the earnest entreaty of his followers, resolved to adopt. But even flight could not have saved them, if those 400 brave men had not arrested the advance of the enemy, till the Margrave and all the rest of the army were in safety, by sacrificing their lives to the last man.

(G. L. Posselts, *Gedächtnissrede auf die Gefallenen.*)

PHACOCHŒRUS. [SUIDÆ.]

PHAEDRUS, a Latin writer of the Augustan age, according to the general opinion. Little is known of his life except that it appears that he was born in Thrace, was brought to Rome in his youth as a slave, found friends at Rome, applied himself to study, and became a perfect master of the Roman language, and was made free by Augustus, who patronised him. He wrote several books of fables in iambic verse, borrowing, as he says in his prologue, his subjects from Aesop. The fables of Phaedrus have long been a favourite work, for the graceful simplicity of their style, the pointedness of their humour, and the general soundness of their morality. [FABLE.] They were first published by Pithou, in 1596, from a MS. supposed to have been written in the tenth century, and which is called the Rosamboanus MS., from the name of the owner of it. Another MS., which existed at Rheims, was destroyed by fire in the last century, but it had been previously collated with Pithou's edition, and the variations had been copied, as well as those in another MS., called Danielinus, and they have been used in the later editions of Phaedrus. The latest edition of Phaedrus has the following title:—'Phaedri Augusti Liberti Fabulæ Aesopiæ, prima editio critica cum integra varietate Codd. Pithoeani, Remensis, Danielini, Perottini, et editionis principis, reliqua vero selecta,' by J. C. Orell, 8vo., Zürich, 1832, with an 'Introduction.' Perotto, bishop of Manfredonia in the fifteenth century, made a collection of Latin fables from Phaedrus, Avienus, and others, for the instruction of his nephew, among which were thirty-two fables which are not contained in the usual editions of Phaedrus, in five books. These fables, 'Fabulæ Novæ,' were published at Naples, in 1808, as an additional or sixth book of Phaedrus. Perotto's MS. however was found much damaged, and the fables were in a mutilated state. Since that time Angelo Mai has discovered in the Vatican Library another MS. of Perotto, in a state of good preservation, with a prefatory letter of the bishop to his friend Mannus Veltrius, of Viterbo, and from this MS. the additional fables have been published in a correct form: 'Phaedri Fabulæ Novæ XXXII., e Codice Vaticano reintegratæ ab A. Maio, Supplementum Editionis Orellianæ,' Zürich, 1832. There seems little doubt now that these fables belong to Phaedrus; they are perfectly similar in style and manner to the rest. The Fables of Phaedrus were also edited by Bentley, and appended to his edition of Terence.

PHÆNICORNIS. [SHRIKES.]

PHÆNO'GAMOUS or PHANÉRO'GAMOUS plants are those which have visible flowers and seeds. The words are used indifferently in contradistinction to Cryptogamous, which includes those plants which either have no sexes or none which are distinctly visible.

PHA'ETON (Ornithology). [TROPIC BIRD.]

PHAKELLOPLEU'RA, the Rev. Lansdown Guilding's name for a genus of *Chitons*, with rather small dorsal plates, and the fleshy zone ornamented with a broad single row of elongated spiculate fasciculi. Example, *Chiton fascicularis*. [CHITONS, vol. vii., p. 96.]

Mr. Swainson (*Malacology*, 1840), not having analysed this tribe, has adopted the genera and arrangement of Guilding. (*Zool. Journ.*, vol. v., p. 25.) Mr. Guilding's genera are:—

1. *Chiton*, which he divides thus:—

*

Zone distinctly scaly.

† Disk subcarinate, transverse-marginal areola distinct. Example, *Chiton squamosus*, Sowerb., *Gen.*, f. 2; *Ch. Capensis*, Gray, &c.

†† Disk rounded, smooth; areola angulate and obsolete. Example, *Chiton marmoratus*, Blainv.

* *

Zone slightly reticulated.

Example, *Chiton lævis*, Lowe, *Zool. Journn.*

* * *

Zone smoothed.

Examples, *Chiton marginatus*, *Linn. Trans.*, viii., p. 21, t. 1, f. 2; *Ch. latus*, Lowe.

2. *Acanthopleura.* The zone thick, fleshy, spinous, spinulous, hairy or rough, &c.

*

Zone spinous.

Example, *Chiton spinosus*, Sow., *Gen.*, f. 1.

* *

Zone spinulous.

Example, *Chiton Carmichaelis*, Gray, *Spicel.*

* * *

Zone granulous.

Example, *Chiton Asellus*, Lowe, *Zool. Journ.*

* * * *

Zone rugoso-granulous.

Example, *Chiton aselloides*, Lowe.

* * * * *

Zone hairy.

Example, *Chiton crinitus*, Wood, *Ind.*

* * * * * *

Zone villous.

Example, *Chiton Peruvianus*, Frembly.

* * * * * * *

Zone mealy (farinosus).

Example, *Chiton cinereus*, Lowe.

3. *Phakellopleura.*

4. *Chitonellus*, Lam.

*

Animal larviform.

Examples, *Ch. lævis*, Blainv.; *Ch. larviformis*, Barrow; *Ch. striatus*, Sow.

* *

Animal shorter, subovate.

Example, *Ch. latus*, Guilding.

5. *Cryptoconchus*, Blainv.

Example, *Cryptoconchus porosus*, Burrow.

See further, *Zool. Journ.*, vol. v. [Chitons.]

These subdivisions may be convenient for the purpose of arrangement; but we are not aware of any generic distinctions in the animals themselves.

PHALACRO'CORAX. [Pelecanidæ, vol. xvii., p. 381.]

PHALÆNA. [Lepidoptera.]

PHALA'NGER. [Marsupialia, vol. xiv., p. 459 et seq.]

PHALANGI'STA. [Marsupialia, vol. xiv., p. 459 et seq.]

PHALANX (φάλαγξ), a name given by the Greeks to the whole of the heavy-armed infantry in an army, but particularly to each of the grand divisions of that class of troops. The number of men composing a phalanx was various, but the general depth of the files in the body so called was sixteen men. The primary signification of phalanx is uncertain; a straight bar or rod of any material appears to have been so called, and the word may have been applied to a corps of troops, in line, from a fancied resemblance in the latter to such object. Eustathius, in his notes on the Iliad, supposes that the term was applied to bodies of soldiers from the clubs or stakes which were the arms of the primitive warriors.

According to the fabulous story in Polyænus, the first who disposed troops in a regular order for battle was Pan, the leader of the army of Bacchus in the expedition to India; he also divided the body of men so formed into two parts, designated the right and left wings, and he gave to the whole the name of *phalanx*. (*Stratag.*, lib. i.) It is easy to imagine that a disposition of troops in solid masses, such as the phalanges were, would be adopted in the earliest ages, when the military art was in its infancy, and when instinct must have led men, in time of danger, to keep themselves collected together for the sake of mutual support. In antient warfare, the success of an action depended on the power of resisting the shock of an enemy's charge, and hence it was important to have the bodies of infantry arranged in deep order, that they might maintain unbroken their position on the ground.

The Greek troops are represented by Homer as so disposed, and the word *phalanges* is, in several parts of the Iliad, applied to the masses of the combatants, both Greeks and Trojans:

> Ἀμφὶ δ' ἄρ Αἴαντας δοιοὺς ἵσταντο φάλλαγγες

(*Il.*, xiii. 126; see also *Il.*, iv. 332, vi. 83); and the close order of the Greeks previously to coming into action is described in *Il.*, xiii. 130, and the succeeding lines.

A like disposition prevailed among the Egyptians in the earliest times of their monarchy, and of this fact some interesting vestiges are preserved in the sculptures on the walls of the temple at Ipsambul and of the palace at Luxor. At the former place an Egyptian army is represented as marching in separate divisions of chariots and foot soldiers drawn up in quadrangular bodies, in ranks, and in close order. Each man of the infantry is armed with cuirass and helmet, and carries a shield and a short javelin; and among the figures is that of Sesostris in full panoply, standing in a highly ornamented car. (Rosselini, *I Monumenti dell' Egitto*, plates 87 to 103.) But, from the nature of the arms and the apparent discipline of the troops, it may be inferred that, at the epoch to which the monuments relate, the tactics of the Egyptians were in a very advanced state, and consequently that the order of battle there represented was in use among that people at a time much more remote than the age of Sesostris.

The antient Jewish army, modelled probably on that of the people who had long held them in servitude, was divided into bodies of 1000 men each, which were again divided into companies of 100 men (2 *Sam.*, c. 18); and it is plain, from other passages in the Scriptures, that these were further subdivided into sections. It consisted both of heavy and of light armed troops: the former wore helmets, coats of mail, and greaves, and in action they carried bucklers and used both spears and swords; the latter also carried shields and used bows or slings. The men who, from the different tribes, assembled at Hebron to confirm the election of David, are described as being armed with spear and shield, and their discipline is indicated by the expression—they could keep rank.

The troops in the army of Crœsus are said by Xenophon to have been drawn up in vast masses, the depth of the Lydians being thirty men, while that of the Egyptian auxiliaries was one hundred; and it is added that the whole army had the appearance of three great *phalanges*. (*Cyropædia*, lib. vii.) It is sufficiently evident therefore that the deep order of battle, with a regular arrangement of the men in rank and file, and some systematical division of the phalanx into sections, prevailed in the earliest times; but it is to the Greek writers that we must go for an account of the particular scales of subdivisions by which the evolutions of the phalanx on the field of battle were facilitated, and which, joined to the high discipline of the troops, gave to the body so denominated the reputation which it enjoyed till the fall of the Macedonian kingdom. The formation of such scales of subdivisions, and some changes in the arms or armour of the men, are probably what are meant when it is said that Lycurgus, Lysander, and Epaminondas introduced the *phalanx* among the Lacedæmonians, the Argives, and the Thebans. The Macedonian phalanx, the formation of which is ascribed to Philip, the father of Alexander, appears to have been a body of 6000 men, chosen for their good military qualities, particularly well armed, and subject to certain strict regulations. And its efficiency was so great, that the name of the country became afterwards very generally applied to what was in reality the usual designation of the bodies of heavy-armed infantry in the Grecian armies.

Xenophon, though constantly using the word *phalanx* in speaking of the whole body of troops which he commanded in the retreat from Cunaxa, when he has occasion to mention the formation or employment of a small body of men for any particular purpose, gives it the name of λόχος, and such body appears to have consisted either of 50 or 100 men. On one occasion, some lochi being detached from the army, two of them, amounting to 100 men, are said to have been cut off (*Anabasis*, lib. i.); and at another time, from an apprehension that the order of the phalanx would be broken in ascending a mountain, the army was divided into separate lochi of 100 men each. (*Ib.*, lib. iv.) But in the 'Cyropædia' (lib. ii.) a division of 100 men is called τάξις, and this is stated to have been subdivided into sections of ten and of five men each.

The scale just hinted at was probably peculiar to the Athenian army, for Xenophon describes the Spartan troops as formed into six μόραι, each commanded by a polemarch; he adds also that the mora was divided into four λόχοι, eight πεντηκοστὺς, and sixteen ἐνωμοτίαι. (*De Repub.*, lib. xi.) The mora is said to have consisted of 600 men, but its strength appears to have varied considerably at different times.

The only existing works expressly written on the subject of the Greek tactics are those of Ælian and his abbreviator Arrian, and these authors lived in the time of Hadrian and Antoninus, that is, long after the age in which the phalanx was superseded by the legion. Therefore, since their descriptions do not agree with what we find concerning the phalanx in the works of Thucydides and Xenophon, it seems reasonable to conclude that they appertain to the state of this body of troops in and subsequent to the times of Philip and Alexander. Ælian makes the phalanx to consist of 16,384 men of the class called ὁπλίται, or heavy-armed infantry; but this must be understood to be the whole body of that denomination in an army, and to be composed of four simple phalanges. Joined to the phalanx is a division (ἐπίταγμα), consisting of half that number of men of the class called ψιλοί, or light-armed troops, and another, called also an epitagma, of cavalry (ἱππεῖς), consisting of one-fourth of the number.

The *peltastæ* (πελτασταί), who are also mentioned by Ælian, but not as appertaining to the phalanx, united in some measure the firmness of the heavy with the agility of the light armed men. They were first instituted by the Athenian commander Iphicrates, and in the course of time they became very numerous in the Greek armies: they served as the guards of the princes, and were often reckoned among the heavy-armed troops.

The number above mentioned is expressly said to have been chosen because it is continually divisible by 2, and thus admits of a very simple distribution of numbers for the subdivisions. What really was the strength of the phalanx when in the field, during the existence of the Macedonian monarchy, is uncertain, and probably it varied much. The army of Alexander at the battle of Arbela is said to have consisted of two great phalanges, each divided into four parts, which were also called by that name; there were besides, two divisions of *peltastæ;* in all, according to Arrian, 40,000 infantry: and there were 7000 cavalry. (*Exped. Alex.*, lib. iii.) At the battle of Raphea, between Antiochus and Ptolemy, there is said to have been a phalanx of 20,000 men in the army of the former. (Polyb., lib. v., c. 8.)

The simple phalanx, according to Ælian, consisted of 4096 men; one half of that number, or 2048 men, constituted the merarchy (μεραρχία); and one-fourth, or 1024 men, was called a chiliarchy (χιλιαρχία). One-fourth of the last constituted a syntagma (σύνταγμα), or xenagy (ξεναγία), which was a complete square of 16 men each way; and the lowest subdivision was called lochus (λόχος), decuria (δεκάς), or enomoty (ἐνωμοτία), which is, by that writer, considered as a single file of 16 men. The officers do not appear to be included in the numbers of the different divisions: each xenagy had its own chief or captain (συνταγματάρχης) at the head, and a lieutenant (οὐραγός) brought up the rear. The leader of a single file is called by Ælian a decurion, perhaps because originally the file consisted of 10 men. A phalangarch commanded each phalanx.

Ælian divides the epitagma of light troops into sections, each of which has half the strength of the corresponding division in the phalanx; the lowest division is the lochus or file, which consists of 8 men. The epitagma of cavalry is divided in the same proportions as the bodies of infantry, down to the lowest subdivision, which is called ἴλη, and is made to consist of 64 men.

The phalangists were armed with helmets, cuirasses, and greaves; and in the early ages they carried an oval buckler and a pike, the latter about 10 feet long. The change introduced by Philip in the arms of the oplitæ consisted in the substitution of a larger shield, and of the σάρισσα, a pike from 18 to 20 feet in length. The arms of the peltastæ seem to have differed from those of the oplitæ chiefly in the buckler (from whence their designation is derived) being round and only about two feet three inches in diameter, and in the pike being short. It is said that Iphicrates, instead of a metal cuirass, allowed to this class of troops only a corslet of strong linen; but apparently this regulation was not always followed. The light-armed troops were frequently provided with a helmet only, and their arms were small javelins, bows, or slings.

A phalanx, in line, was considered as being constituted of two equal parts or wings (κέρατα); there was no central division, but the place of junction of the two wings was called the ὀμφαλός. In the usual order of battle it was drawn up with its front parallel to that of the enemy, but it not unfrequently happened that one wing was kept retired. This last method was practised by Epaminondas at the battle of Leuctra; the wing engaged was strengthened so as to have 50 men in depth, and the line gradually diminished to the opposite extremity, where it was only six men deep. Sometimes also two phalanges advanced in columns, with their heads united, the two lines gradually diverging to the right and left; and this is that disposition which was called ἔμβολον, or the wedge.

The phalanx was frequently drawn up in the form of a quadrangle, which might be solid or hollow, according to circumstances; and this disposition was called the plinth (πλινθίον), or the plæsium (πλαίσιον). When a double phalanx was formed with their fronts in reversed positions, the order was called αμφίστομος. The order called αντίστομος seems to have been similar to the last, except that the men faced in opposite directions, from the centre towards the wings.

When standing at open order, each soldier in the phalanx was allowed a square space about six feet each way; but when prepared for action, this was reduced to three feet, and occasionally to about eighteen inches. The file-leaders and the rear-rank men were always chosen from the best of the troops, for on the first depended chiefly the success of the charge, and the latter performed the important duty of urging on the men immediately before him, in order that the whole body might not give way by the counter-pressure of the enemy's mass.

After the introduction of the Macedonian sarissa above mentioned, the phalanx might present a formidable array of five ranks of such weapons projecting horizontally before the front of the line; for, admitting the men to be three feet from each other in depth, and that each man held in his hands about six feet of the length of the weapon, the point of that which belonged to the fifth man would project two feet beyond the file leader. Ælian also mentions another and perhaps a preferable practice, which was that of giving to the men from the first to the third or fourth rank spears successively longer in proportion to the distance of the rank from the front; in which case all those weapons must have projected equally before the line of troops.

The position of the phalanx was sometimes changed by a wheel of the whole body on either extremity as a pivot; and this was done with the men drawn up in close order. But the reversion of the front was performed in one of the three following ways:—The Cretan method, as it was called, consisted in making each file countermarch almost upon the ground it occupied, the file-leader going to the right-about, and moving to the rear, all the men of the file following him till the rear-rank man came into the line which was before the front. The Spartan method was also performed by a countermarch, but the file-leader moved to the rear, followed by the other men, till he arrived at a distance from his first place equal to twice the depth of the phalanx, the rear-rank man only changing his front. Lastly, the Macedonian method was performed by the front-rank man going right about on his own spot, the others passing him in succession and arranging themselves behind him. These movements appear to have been preferred by the Greeks to a simple change of front to be effected by making each man turn upon the ground he occupied, since they allowed the file-leaders to constitute always the foremost rank of the line.

The number of men in front of the phalanx was doubled by causing every second man in the depth to move up to the interval between every two men in the rank immediately before him; thus reducing the depth of the phalanx to eight files without extending the front. And when the front was to be extended without increasing the number of men in it, the troops merely, by a flank movement, opened out from the centre each way. Arrian justly observes that these evolutions should be avoided when in presence of the enemy; and he adds that it would be preferable to extend the front by bringing up cavalry or light troops to the wings.

On a march, the phalanx was thrown into a column, whose breadth depended on that of the road; and a formation of some separate bodies, consisting of 100 men each, for the purpose of protecting the main body while returning to its former order after having passed a defile, is mentioned by Xenophon (*Anabasis*, lib. iii.) as being then, for the first time, employed. The march of two phalanges in parallel and contiguous columns is stated to have been sometimes made by the columns keeping their proper fronts towards the exterior; but sometimes both columns were in like positions, the front of one and the rear of the other being towards the exterior, on the two sides of the line of march.

The strength of a Grecian army consisted in the deep array of its heavy infantry. No body of men less protected by defensive armour could make any impression upon the solid phalanx: and the latter, by the momentum of its charge, could not fail to overwhelm any troops who were differently formed. But the advantage of the phalanx, while it continued embodied, did not extend beyond the immediate field of battle; and the enemy, if he thought proper to decline an engagement, could, without interruption, except that which might arise from the light-armed troops and cavalry, ravage the country, and by cutting off its supplies compel the army to retreat. The phalanx moreover could only be advantageously employed on ground which was nearly level and free from obstacles; since whatever tended to derange its compact order, necessarily diminished or annulled the effect of its charge. At the battle of Issus, the phalanx of Alexander, while in a state of disorder, as the troops were passing the river, was engaged with the Greeks in the service of Darius; and though it succeeded in repelling the enemy, it sustained considerable loss. (Arrian, *Exped. Alex.*, lib. ii.)

Polybius, in comparing (lib. xvii., extract 3) the efficiency of the phalanx with that of the Roman legion, observes that the latter never opposed the former on a line parallel to its front, but always with one wing thrown back; by which means it broke the line or else compelled the phalanx to change its disposition; in either case there were formed intervals of which the legionary soldiers could avail themselves to engage the phalangists in flank, and thus render their close array and their unwieldy weapons useless.

PHALANX. [SKELETON.]

PHA'LARIS, a tyrant of Agrigentum in Sicily, of whom very little is known. He was a native of Astypalæa in Crete. It is generally agreed that he reigned sixteen years, but accounts differ in regard to the commencement of this period. Eusebius and Suidas place his accession in Ol. 52 (B.C. 570); Jerome, in Ol. 53, 4 (B.C. 565). A still earlier date than the former has also been given, namely, Ol. 31, 2 (B.C. 655); but this is contradicted by the statement of Aristotle (*Rhetor.*, ii. 20, sec. 5), who speaks of Phalaris as the contemporary of Stesichorus, and by Diodorus Siculus (*Excerpta Vaticana*, xxviii., p. 25), who mentions Phalaris between Æsop and Crœsus. Phalaris was deposed and put to death by Telemachus, the great-grandfather of Theron and Xenocrates, who flourished in the time of Pindar. (*Schol. Pind.*, Ol. 3, 68.) Phalaris was infamous for his cruelty, and especially for the particular device, which he owed to Perillus, of burning the victims of his savage tyranny in a bull of bronze, in order that he might enjoy the pleasure of hearing their cries. (Cic., *De Republ.*, iii. 30, sec. 41.) This appears to have been the tradition widely spread even in the time of Pindar, who says (*Pyth.*, i. 95):—'Crœsus's reputation for hospitality fades not away, but an evil report everywhere attaches itself to the cruel Phalaris, who burned people in a brazen bull; nor is he praised in festal meetings where the harps resound in the hall and where the youthful choruses sing.' Perillus, the maker of the bull, was the first of those who perished in this way; and when Phalaris was deposed, the mob rose against him, and practised upon him the same cruelty to which he had often subjected others. (Cicero, *Off.*, ii. 7, § 26; *De Nat. Deorum*, iii. 33, § 82; *Verr.*, v. 56, § 145; *De Fin.*, iv. 23, sec. 64.) Ovid, *Ibis*, 439, says that his tongue was first cut out (*lingua prius ense resecta*); and Heracleides Ponticus, that his mother and his friends were burnt with him. The other accounts of his death are not trustworthy. (Bentley's *Phalaris*, p. 135.) This bull was carried to Carthage: the image which was shown by the people of Agrigentum in the time of Timæus was not the bull of Phalaris, but a representation of the river Gela; the bull of Phalaris was however afterwards restored to the Agrigentines by Scipio. (Cic., *Verr.*, iv. 33, sec. 73; Diodorus Siculus, p. 614, 90.) On the bull of Phalaris, see Ebert, Σικελίων, Regiomont., 1830, p. 10, seqq.) There were other stories about this tyrant: as that he was an eater of human flesh (Aristot., *Ethic. Nicom.*, vii. 5, § 7); that he used to devour sucking children (Clearchus, apud Athenæum, p. 396); and that he even fed upon his own son (see the passages quoted by Bentley, *Phal.*, p. 369). The name of Phalaris is best known in modern times from the celebrated controversy between Bentley and Boyle with regard to the authenticity of the epistles attributed to him, the spuriousness of which was most satisfactorily established by Bentley in his admirable 'Dissertation on the Epistles of Phalaris.' These epistles, which were probably written by some rhetorician or sophist in the time of the Cæsars, are utterly worthless in a literary point of view, though Sir William Temple ventured to select them as one of the greatest works of antiquity. They have been reprinted several times since Boyle's notorious edition. The best edition is that by Schäfer (*Phalaris Epistolæ, Gr. et Lat., cum notis Lennepii, Valckenaerii, et Schaeferi*, Lips., 1823).

PHA'LARIS, a small genus of grasses, of which the seed of one of the species is extensively employed as food for birds, and commonly known as Canary seed. The species of the genus are found in warm parts of the world; but *Phalaris canariensis*, a native of the Canary Islands, is naturalised in Europe, and is the only one which is cultivated. The seed is imported into the South of Europe from Barbary. It is also cultivated in the Isle of Thanet and some other parts of Kent. It is sown in February and reaped about the end of September, but being a plant of southern climates, and late in ripening its seed, it is an uncertain crop. The produce is from thirty to forty bushels per acre, but sometimes even fifty bushels are obtained.

PHA'LAROPE. [SCOLOPACIDÆ.]

PHA'LERIS. [AUK, vol. iii., p. 100.]

PHALE'RUM. [ATHENS.]

PHALLU'SIA, M. Savigny's name for a subgenus of Ascidians, which differs from *Cynthia* in not having the branchial sac plicated; their test or case is gelatinous. [CYNTHIA; BOLTENIA.]

PHANERO'GAMOUS. [PHÆNOGAMOUS.]

PHANODE'MUS, an historian of Athens, is referred to by Dionysius of Halicarnassus, as having written upon Attic antiquities. (Hoffmann's *Lexicon;* Fabricius, *Bibl. Græca.*) Fragments of Phanodemus, together with some of Demon, Clitodemus, and Ister, were edited by Siebelis, 8vo., Leipzig, 1812.

PHA'RAMUM, De Montfort's name for a genus of microscopic *Foraminifera*, generally arranged under the genus *Robulina* of D'Orbigny. [FORAMINIFERA, vol. x., p. 348.]

PHARISEES, a sect among the antient Jews. The name is derived from the Greek Φαρισαῖοι, and this most probably from the Hebrew פָּרַשׁ, *parash*, to separate. Suidas says, 'The Pharisees are by interpretation ἀφωρισμένοι (the separated), because they divided and separated themselves from all others, in exactness of life and in attention to the injunctions of the law.'

The origin of this sect is unknown. Josephus, who was himself one of the Pharisees, speaks of them as flourishing long before he was born. He says (*Antiq.*, b. 13, c. 9), 'At this time (about 150 B.C.) there were three sects of the Jews, the Pharisees, the Sadducees, and the Essenes.' On several occasions he describes the Pharisees as the chief sect, and as possessing great authority among the people.

They believed in the existence of angels and spirits, and held the doctrine of the resurrection; but their notion of the latter appears to have been Pythagorean, namely, that there is a resurrection of the soul only by a transmigration into another body. From the benefits of this resurrection they shut out all the notoriously wicked, consigning them at once to eternal misery, upon the separation of the soul from the body. While the Essenes maintained that all things were ruled by absolute fate, and the Sadducees that all things were under human control, the Pharisees adopted a middle course, maintaining that some things were predestinated, and others left for men to determine. It was a leading maxim of the Stoics that some things were in our power, and others not in our power; and Josephus tells us that the sect of the Pharisees was very much like that of the Stoics.

But they were mainly distinguished by their zeal for 'the traditions of the elders,' to which they attached an importance equal to that of the Mosaic writings; and it was from a strict adherence to these traditions, as well as from an observance of the punctilios of the law itself, that they were called Pharisees. Several of these traditions are mentioned in the New Testament, but they are only a small portion of the whole. 'To go through them all,' says Prideaux, would be to transcribe the Talmud, a book of twelve volumes in folio.'

The Pharisees are represented in the New Testament as a hypocritical, proud, and arrogant people, pretending to be emphatically 'the separated,' trusting to themselves that they alone were righteous, and despising all other men. This was their character as a body; but there were among them individuals free from these bad qualities, such as Nicodemus, Joseph of Arimathæa, Gamaliel, and, as some think, Simeon, who uttered the hymn called 'Nunc dimittis,' to whom must be added Josephus, their historian.

(Josephus, *Antiq.*, xiii. 9, 18; xvii. 3; xviii. 2; *De Bell. Jud.*, ii. 7; *De Vitâ suâ;* Suidas, Φαρισαῖοι; Prideaux, *Connection.*)

PHARMACOLITE, native arseniate of lime; it occurs crystallized and fibrous, and there is a variety, called haidingerite, which differs in crystalline form and composition.

The primary form of pharmacolite is an oblique rhombic prism. Cleavage parallel to the oblique diagonals of the terminal planes. Fracture uneven. Hardness 2·0 to 2·5; easily scratched. Colour white. Lustre vitreous. Transparent; translucent; opaque. Specific gravity 2·640 to 2·8.

Fibrous pharmacolite occurs in white diverging needles and small globular and botryoidal masses, which are frequently coloured by arseniate of cobalt.

When heated by the blowpipe, pharmacolite emits the alliaceous smell, and fuses with difficulty into a white enamel; it dissolves in nitric acid without effervescence.

This mineral is found at Andreasberg in the Harz, and in Thuringia, and at Wittichen, near Fürstenberg in Germany, and some other places.

The pharmacolite of Wittichen was analyzed by Klaproth (1), and that of Andreasberg by John (2); the results were

	(1)	(2)
Arsenic Acid . .	50·54	45·68
Lime . . .	25·00	27·28
Water . . .	24·46	23·86
	100·	96·82

Haidingerite.—Primary form a right rhombic prism. Cleavage parallel to the short diagonal of the terminal planes, very distinct. Hardness 2·0 to 2·5. Colour white, and streak the same. Lustre vitreous. Translucent; transparent. Specific gravity 2·84. It accompanies the pharmacolite of Baden, and was found by Dr. Turner to consist of arseniate of lime 85·68, water 14·32.

PHARMACOPŒIA, a book published by the colleges of physicians with the sanction of government, containing directions for the preparation of medicines.

PHA'RMACY, in a comprehensive sense, means the department of natural science which treats of the collection, preparation, and preservation of medicines, and also of the art of dispensing them according to the formulæ or prescriptions of medical practitioners. It is however more commonly used in a limited sense, as a branch of chemical science, and termed pharmaceutical chemistry, or the application of the laws of chemistry to those substances which are employed for the cure of diseases, so as to render them more commodious, or their administration more easy, and their action more perfect and certain. It should not be understood as merely depending upon some mechanical processes, such as trituration, rasping, or other means of subdivision, or even the simpler chemical actions involved in the processes of infusion or decoction, but as requiring a knowledge of vegetable physiology, and an acquaintance with the chemical constitution of the substances to be prepared. In many continental nations this department is the subject of very strict legal enactments, and forms an important part of medical police, especially as regards the dispensing of poisonous drugs; while in Britain any one who chooses may affix the terms chemist and druggist to his name, and may deal in the most useful or dangerous ingredients, without that previous education which would fit him to be the appropriate assistant of the physician, whose most judicious plans are often frustrated by the ignorance or carelessness of those to whom the compounding of his prescriptions is entrusted. [Materia Medica.]

PHA'RNACES. [Pontus.]

PHAROS. [Alexandria.]

PHARSA'LIA. [Cæsar; Thessaly.]

PHARYNX is the cavity in which the food is received in its passage from the mouth to the œsophagus or gullet. In man it is somewhat funnel-shaped, having its widest part above, where it is fixed to the base of the skull. The nasal passages, the mouth, and the air passages, open into the pharynx in front; behind, it is attached to the spinal column; and at its sides it is bounded by the deep vessels and muscles of the neck. It is lined by a mucous membrane, but is chiefly composed of layers of strong muscular fibres, called the constrictors of the pharynx, by whose successive contractions the food received from the mouth is gradually forced from above downwards into the œsophagus.

PHASCO'GALE. [Marsupialia, vol. xiv., p. 456.]

PHASCOLA'RCTOS. [Marsupialia, vol. xiv., p. 461.]

PHASCO'LOMYS, M. Geoffroy's name for the *Wombat.* [Marsupialia, vol. xiv., p. 463, et seq.]

PHASE (φάσις, *phasis*, appearance). When a phenomenon changes its character gradually, any particular state which it is necessary to distinguish is called a phase. Thus we have the phases of the moon, meaning the different forms which the enlightened part takes during the month; the phases of the weather, meaning the succession of heat and cold, wet and dry, &c.

PHA'SEOLUS, a genus of plants of the tribe Phaseoleæ, in the natural family of Leguminosæ. The name is said to be derived from *phaselus*, a little boat, which the pods are thought to resemble; but it may be that the meaning of 'boat' is derived from the resemblance of a boat to the form of a bean. Two species are very well known in this country, *P. vulgaris*, the common Kidney bean, and *P. multiflorus*, the Scarlet runner; their unripe pods being much esteemed as legumes, and also for pickling. The ripe seeds are however employed on the Continent, and form the *haricots* of the French. The genus is however one of which the species are indigenous in tropical parts both of the Old and New World. Several are cultivated in India, and are some of the principal articles of the agriculturist's attention, as the ripe seeds of several species form pulses which are much used by the natives as a portion of their diet, and some of which, like the Kidney bean, abound in nutritious matter.

The genus Phaseolus is characterised by having a bell-shaped two-lipped calyx. The corolla is papilionaceous, and has the keel, as well as the diadelphous stamens and the style, spirally twisted. The Legume is compressed or cylindrical, with two valves, and is many-seeded, with more or less conspicuous cellular partitions between the seeds. The hilum of the seed is oval oblong. The plants are herbaceous or suffrutescent in habit. The leaves are pinnately trifoliolate, the leaflets with partial stipules. Racemes axillary. Pedicels usually in pairs, single flowered.

Phaseolus vulgaris (Kidney Bean) is said to be a native of India, but Dr. Royle states that seeds were brought to him from Cashmere, and he is therefore inclined to consider that it was introduced into Europe from the most northern parts, such as Caubul and Cashmere, and that this accounts for our being able to cultivate it at a lower temperature than other species of the genus. *P. multiflorus*, or the Scarlet runner, is a native of South America. Both are delicate, and cannot be safely planted in the open air till the beginning of May. In a stove or pit, green pods of the dwarf kinds may be gathered all the winter, and they have this advantage, Mr. Loudon observes, over forced productions of the fruit kind which require to be ripened, that the pods are as good from plants in the stove in midwinter, as from those in the open garden in midsummer. The Kidney bean is an article of field culture in France, America, and in most warm countries. Speechley suggests that it might become an object of field culture in this country, and be useful in times of scarcity more especially, as on good land it will flourish and grow luxuriantly even in a dry parching season, in which respect it differs from most other culinary vegetables.

In India several species of Phaseolus are extensively cultivated:—

Phaseolus Mungo, or Moog, is one of the dry leguminous grains of India, which are of great value whenever the periodical rains fail and rice cannot be grown, and famine is the consequence. It requires a strong rich dry soil, and is raised in the greatest quantities on rice lands during the cold season. In from seventy-five to ninety days it is ready to cut, and yields about thirty-fold. The ripe grain is well tasted, nutritious, and is considered wholesome.

P. Max., Kala Moog of the natives, and black Gram of the English, is like the former, but distinguished by its black seeds, and is, like it, found in a cultivated state: it takes about the same time to ripen, and yields nearly the same produce.

P. radiatus, called by the natives Mash and Oorud, is, like the two former, found in a cultivated state, and is the most esteemed of all the Indian leguminous plants. Besides using it as an article of diet, the natives make bread of the meal for some of their religious ceremonies.

P. aureus, or Sona Moog of the Bengalees, is found in a cultivated state in the Bengal presidency, but is not known on the Coromandel Coast. It is sown, like the others, about the end of October or beginning of November, and reaped in February on the beginning of March.

P. aconitifolius, Moth of the natives, is cultivated in the north-western provinces, and used for feeding cattle.

PHASES OF THE MOON. [Moon.]

PHASIANE'LLA. [Trochidæ.]

PHASIA'NIDÆ. [Pavonidæ; Pheasants.]

PHASIS (*Φάσις*), the principal river in antient Colchis, and called at present the Faz, and sometimes the Rion, rises in Armenia, according to Strabo (xv. 498), and among the Moschi, according to Pliny (*Hist. Nat.*, vi. 4). It flows in a westerly direction into the Black Sea. It was navigable in antient times for large ships for thirty-eight miles from the coast, and for smaller vessels as far as the fort of Sarapana (*Sharapan*), on the boundaries of Colchis and Iberia, from which place goods were conveyed by waggons in four days to the river Cyrus. (Strabo, xv. 498; Plin., *Hist. Nat.*, vi. 4.) There are no antient remains at Sharapan. The Phasis was sometimes considered as the boundary between Asia and Europe (Herod., iv. 45), and was regarded in the time of Augustus as the northern boundary of the Roman dominions in that part of Asia. (Strabo, vi. 288.) The Phasis received many affluents, of which the principal were the Glaucus and the Rion, by the latter of which names the Phasis itself is sometimes called. The Glaucus appears to be the modern Quirilla, which comes from Elburz. From the junction of the Rion and Quirilla the river is navigable for boats at all seasons, has no obstructions, and is from twenty to thirty feet deep, with a current of about two miles and a half an hour. It flows through a level country, which is lower than the banks of the river. There is a bar at the mouth of the Phasis, with only six feet water, the only circumstance that prevents the river being entered by the largest vessels. The navigation of the Phasis is now entirely in the possession of the Russians. At Poti, near the mouth of the Phasis, the Russians have a station or castle. Kootais on the Rion is the seat of the Russian government of Imirétia.

In antient times there were one hundred and twenty bridges over the Phasis (Strabo, xv. 500; Plin., *Hist. Nat.*, vi. 4), and many towns upon it, of which the most important were Æa, the old capital of the Æetes, which is celebrated in the legends of the Argonautic expedition [Argonauts], and Phasis (*Poti*), situated at its mouth. There are no remains of antiquity on the Phasis. On the banks of the river there were in antient times, as is also the case at the present day, great numbers of pheasants, which are said by Martial (*Epig.*, xiii. 72) to have been brought into Greece by the Argonauts, and to have been called Phasiani, from this river.

The Phasis was noted in antient times for the excellence and purity of its waters. Arrian, in his 'Periplus of the Euxine Sea,' informs us that water taken from it will preserve its goodness for ten years; and though this is doubtless an exaggeration, it serves to show in what high estimation its waters were held at that time. [Georgia, p. 176.] (*London Geog. Journal*, vol. iii., p. 33, &c.)

PHAVORI'NUS VARINUS, a native of Favera, a place near Camerinum in Italy, whence he called himself Favorinus, in Greek Phavorinus (Φαβωρίνος). His family name was Guarino, which he turned into Varinus (Βαρίνος). He is also called Camers, from the town of Camerinum. The precise time of his birth is unknown, but it was probably some years after the middle of the fifteenth century. He is represented, about 1490, as a pupil of Angelo Poliziano, and as exquisitely skilled in Greek and Latin. He devoted himself to the service of the church, and joined the order of the Benedictines. In 1512 he became librarian to Giovanni de' Medici, afterwards pope Leo X.; and in 1514 he was made bishop of Nuceria, over which diocese he presided twenty-three years. He died in 1537.

Phavorinus, assisted by two other eminent scholars, Charles Antenoreus and Aldus Manutius, edited, in 1496 'Cornu Copiæ et Horti Adonidis,' consisting of seventeen grammatical tracts in Greek, selected from thirty-four antient grammarians. In 1517 he published a collection of apophthegms from Stobæus, which he dedicated to Leo X. But the work by which he is chiefly known is his Greek Lexicon, which, after the labour of many years, he completed in the lifetime of Leo X. It was published at Rome in 1523, fol., and reprinted at Basle in 1538, fol., under the direction of Joachim Camerarius, with several improvements. The last edition, still further improved, was printed at Venice, in 1712, by Antony Bortoli, in a neat type and in a handsome form. The first edition is beautifully printed and the paper is excellent; but the edition of 1712 is by far the best for all the purposes for which a lexicon is consulted. This very useful lexicon is compiled from the various preceding lexicons, grammars, &c., or, as the title expresses, 'from many and different books.' The words are given in alphabetical order, and all the definitions and explanations are in Greek, which Phavorinus is said to have spoken and written as well as a native Greek. Henry Stephens appears to have been greatly indebted to the work of Phavorinus in the compilation of his Greek Lexicon, though he nowhere acknowledges his obligation.

(Fabricius, *Bibliotheca Græca;* Roscoe, *Life of Leo X.; Quarterly Review*, vol. xxii.)

PHEASANTS. If we owe to America that useful and sapid bird the Turkey, we are indebted to Asia for those equally desirable additions to our homesteads, preserves, and farm-yards, the *Peacocks*, the *Pheasants*, and our common *Poultry*.

The views of Mr. Vigors and some other ornithologists with regard to the *Phasianidæ* are sketched in the article Pavonidæ.

Mr. G. R. Gray arranges the *Phasianidæ* as the second family of *Rasores*, *Cracidæ* being the first; and he divides the *Phasianidæ* into the subfamilies *Pavoninæ*, *Phasianinæ*, *Gallinæ*, and *Meleagrinæ*. The *Pavoninæ* and *Meleagrinæ* are noticed in the article Pavonidæ. The *Phasianinæ* consist of the genera *Argus*, *Phasianus*, *Syrmaticus*, *Thaumalea*, and *Gennæus*. The *Gallinæ* comprehend the genera *Euplocamus*, *Monaulus*, *Lophophorus*, *Gallus*, and *Tragopan*.

Phasianus. (Linn.)

Generic Character.—*Bill* of mean length, strong; upper mandible convex, naked at the base, and with the tip bent downwards. *Nostrils* basal, lateral, covered with a cartilaginous scale; cheeks and region of the eyes destitute of feathers, and covered with verrucose red skin. *Wings* short, the first quills equally narrowed towards their tips, the fourth and fifth the longest. *Tail* long, regularly wedge-shaped, and composed of eighteen feathers. *Feet* having the three anterior toes united by a membrane as far as the first joint, and the hind toe articulated upon the tarsus, which, in the male birds, is furnished with a horny cone-shaped sharp spur. (Gould.)

The type of this genus is generally considered to be the *Common Pheasant, Phasianus Colchicus*, Linn., a bird which, though not originally British, is completely naturalised in our islands, and indeed appears to adapt itself with great facility to most countries where ordinary care is taken to preserve it and the temperature is not too low for its constitution. The species is too well known to need description, but an account of its introduction into Europe generally and into our own country particularly, together with a summary of its habits, will be expected, and we shall endeavour to lay before the readers some information on these points.

If we are to listen to the tales which form that period of history which borders upon fable, we owe this ornament to our preserves and tables to Jason and his companions, who brought it from Colchis, in the good ship Argo. Martial thus notices its introduction into Europe (lib. xiii., ep. 72): *Phasianus loquitur*—

> Argivâ primum sum transportata carinâ;
> Aute mihi notum nil nisi Phasis erat.'

In Greece it soon became known under the name of *φασιανός* (Phasianus) and *φασιανικός ὄρνις* (Phasian bird). (Aristoph., *Clouds*, 110; *Birds*, 68.) Indeed it had become sufficiently celebrated in the time of Aristophanes to form a proverb,—'Not if you would give me the pheasants which

Leogoras feeds,' says Strepsiades, in the *Clouds* (109, 110). Aristotle writes succinctly but clearly of the habits of the pheasant as a well-known bird (*Hist. Anim.*, v. 31; vi. 2); nor is Athenæus silent concerning so delicate a dish, which appears to have become more common as luxury waxed strong, nor regarding the royal conduct of Ptolemy, who, though he kept them and provided them with hens (*νομάδας ὄρνιθας*) for multiplication, being aware of their excellence for the table, appears not to have tasted them. From the same author it would appear that the antients, contrary to the opinion of modern epicures, thought the cock birds the best. (*Deipn.*, xiv., lxix., p. 654.) It is the *Phasianus* of the antient Italians (Pliny, *Nat. Hist.*, x., xlviii.; xi., xxxvii.), but seems to have only been within reach of the wealthy. Thus Martial (xiii., xlv., *Pulli gallinacei*),—

> 'Si Libycæ nobis volucres et Phasides essent,
> Acciperes: at nunc accipe cortis aves.'

and again, in the epigram addressed to Bassus (iii. 58), which gives so pretty a picture of a genuine rural Roman villa, and so agreeably fills the imagination with country sights and sounds,

> 'Vagatur omnis turba sordidæ cortis,
> Argutus anser, gemmeique pavones,
> Nomenque debet quæ* rubentibus pennis,
> Et picta perdix, Numidicæque guttatæ,
> Et impiorum phasiana Colchorum.
> Rhodias superbi fæminas premunt galli,
> Sonantque turres plausibus columbarum.
> Gemit hinc palumbus, inde cereus turtur.'

The pheasant has now been spread over the whole of temperate Europe, and the greater part of the old Continent; and it is probable that it will be introduced with success wherever the face of the country and the supply of food are congenial to it, and the temperature does not vary too much from that of its native river, the modern Rion, along whose banks Mingrelia, formerly Colchis, extends, and lies between 42° and 43° N. lat., and 41° 19′ and 42° 19′ E. long. [GEORGIA, vol. xi., p. 176; PHASIS.] It is even said to be common in Siberia, a much colder climate, which would prove the facility with which it adapts itself to temperature; and an attempt has, we believe, been made to introduce it into North America, a locality well suited to its habits.

The south of Europe owed the pheasant, in all probability, partially to the Greeks, and more proximately to the Romans; it is the *Fasiano* of the modern Italians, and *Faisan* of the French. More doubt hangs about its introduction into Great Britain, and the time of that introduction. We are told that the price of one was fourpence in the time of our first Edward (A.D. 1299). In 'The Forme of Cury,' which is stated to have been compiled by the chief master-cook of King Richard II., we find a receipt 'for to boile Fesant, Ptruch (partridges), Capons, and Curlew,' which carries us back to 1381. We read of the

> 'Fawkon and the Fesaunt both,'

in the old ballad of the 'Battle of Otterbourne.' At the 'Intronazation of George Nevell,' archbishop of York, in the reign of our fourth Edward, we find among the goodly provision, 'Fessauntes, 200.' In the 'Northumberland Household-Book,' begun in 1512, 'Fesauntes' are valued at twelve pence each. In the charges of Sir John Nevile, of Chete, at Lammas Assizes, in the twentieth year of the reign of King Henry VIII., we find twelve pheasants charged twenty shillings; and they seem to have rapidly increased in price, as, among the expenses of the same Sir John Nevile, for, as he writes it, 'the marriage of my son-in-law, Roger Rockley, and my daughter Elizabeth Nevile, the 14th of January, in the seventeenth year of the reigne of our soveraigne lord King Henry VIII.,' is the following: 'Item in Pheasants 18, 24 shillings.' We trace the birds in 'A. C. Mery Talys,'† printed by John Rastell, where we read of 'Mayster Skelton, a poyet lauryat, that broughte the bysshop of Norwiche ii. fesauntys.' Rastell began to print as early as 1517, and ceased in 1533. In Turbervile's 'Booke of Falconrie' the 'Fezant' and 'Feasants'—for, with the licence of the time, it is spelled both ways—are mentioned as the subjects of hawking, and so the bird may be traced as a dish for the table, or the object of field sports, down to the present time.

Habits, Reproduction, &c.—Hen pheasants in this country begin to lay in April, and deposit from eight or ten to fourteen olive-brown eggs, in a rough nest on the ground. Sometimes two will lay in the same nest. The young make their appearance towards the end of May or beginning of June.

Where the country is favourable, it is easy to get up a head of pheasants, with the aid of good keepers; but it is more difficult to keep them at home, for they are wandering birds, and will often leave the place where they are bred, in search of food more agreeable to them and localities more congenial to their habits. Warm covers and water are absolutely necessary; and if they are plentifully supplied with grateful food, but few of them will become vagrants. Jerusalem artichokes, potatoes, and buckwheat, as well as barley, are favourites. Small stacks of the latter grain in the straw are frequently placed about the preserves, and there the pheasants may be seen scratching at their feeding-time; but this mode of supply is objectionable, as the poacher soon finds out the several points of attraction, and avails himself of them accordingly. Mr. Yarrell states that one good mode of inducing them to stop at home is to sow, in summer, beans, peas, and buckwheat mixed together, leaving the whole crop standing on the ground. The strong and tall stalks of the beans carry up and sustain the other two, and all three together afford, for a long time, food and cover. (*Hist. of British Birds.*) The same author tells us that at the end of autumn he has found the crops of the birds distended with acorns, of so large a size that they could not have been swallowed without great difficulty. In December, 1834, we saw eight ripe acorns and a ripe hazel-nut taken out of the crop of a hen pheasant from Sussex. The acorns had begun to germinate with the heat and moisture of the crop, and they were sent up to the gardens of the Zoological Society in the Regent's Park, and there planted. For autumnal and winter home-feeding we have seen potatoes used with excellent effect, not only in keeping the birds from wandering, but in increasing their weight and fatness. Carts loaded with raw potatoes were, from time to time, driven into the covers, and the potatoes were scattered about by hand. The pheasants soon found them out and throve accordingly, without being collected together at particular spots, as they too often are to their destruction. They are very general feeders; neither blackberries, sloes, nor haws come amiss to them, and grain, seeds, and tender leaves find their way into the pheasant's crop as well as insects. Mr. Selby observed that these birds sought after the root of the acrid bulbous crowfoot (*Ranunculus bulbosus, Common Buttercup*) in May and June, and a friend informed Mr. Yarrell that they also feed on the Pilewort Crowfoot (*Ranunculus ficaria*). Mr. Selby further states that the bulb of the garden tulip is an article of diet which the pheasant omits no opportunity of obtaining; and which, however deeply buried, the bird is almost certain to reach by means of its bill and feet. The size to which these birds attain when well fed is considerable. In the catalogue of Norfolk and Suffolk birds, by the Rev. Revett Sheppard and the Rev. William Whitear (*Linn. Trans.*, vol. xv.), the weight of a cock pheasant killed at Campsey Ash, where the birds were well fed with potatoes, buckwheat, and barley, is stated at four pounds and a half. 'Some winters since,' says Mr. Yarrell, 'my friend Mr. Louis Jaquier, then of the Clarendon, produced a brace of cock pheasants which weighed together above nine pounds. The lighter bird of the two just turned the scale against four pounds and a half; the other bird took the scale down at once. The weights were accurately ascertained, in the presence of several friends, to decide a wager, of which I was myself the loser.'

Among the diseases and disorders to which the pheasant, in common with other gallinaceous birds, is subject, the fatal *gapes* holds a prominent place. The cause of this disease is an intestinal worm, which adheres to the internal surface of the trachea, and causes death by suffocation, sometimes arising from inflammation of the part, and not unfrequently by actual obstruction. This *entozoon* is *Syngamus trachealis* (*Distoma lineare* of Rudolphi, *Fasciola Trachea* of Montagu), and a most curious animal it is. The bifurcation of the anterior extremity was taken by earlier observers for a double head, and thence probably came the name *Distoma* (double-mouth); but this bifid termination is in reality due to the two sexes. The female is long; and the short male is affixed to her for life by means of an integument which holds him to her, but which, if cut open, exhibits an otherwise free and distinct animal. In the museum of the Royal College of Surgeons, Nos. 199, 200, 201 (*Preparations of Natural History in Spirit*), exhibit this destructive worm. The first shows several specimens from the trachea of a chicken; the second consists of a small portion of the trachea of a bird laid open, and exhibiting one of this species which has lost its original pink colour and become blanched in the spirit; and in the third is to be seen the trachea of a partridge completely choked up by them. Mr. Selby observes that many recipes for the cure of this fatal malady (which is provincially called the *Nax* in Northumberland) have been suggested, but that none of them seem to be effectual, except the one recommended by Montagu, namely, fumigating by tobacco, found to be an infallible specific when administered with due care and attention. The mode of administering this remedy is by putting the young pheasants, turkeys, chickens, or partridges affected into a common wooden box, into which the fumes are blown by means of a tobacco-pipe. That this often succeeds is true, but we cannot confirm its infallibility in all cases: a pinch of common salt, put far back into the mouth of the patient so as to reach the upper part of the trachea, is a neater and less operose method of cure. With reference to this, it has occurred to us that we never heard of any pigeons being affected with the gapes, and the fondness of these birds for salt is well known. We have heard of a sparrow being attacked by this *entozoon*, but we did not see the case.

---

* The Flamingo.

† Alluded to in Shakspere's 'Much Ado about Nothing.'

The assumption of the plumage of the cock pheasant by the female, when, through old age or organic defect, she is no longer capable of reproducing the species, is by no means uncommon, not more rare indeed, if so much, as it is in the peafowls [PAVONIDÆ, vol. xvii., p. 334], common poultry, &c.; indeed John Hunter (*Animal Economy*) remarks that this change has been principally observed in the common pheasant. 'It has been observed,' says Hunter, 'by those who are conversant with this bird when wild, that there every now and then appears a hen pheasant with the feathers of a cock; all however that they have described on the subject is, that this animal does not breed, and that its spurs do not grow. Some years ago one of these was sent to the late Dr. William Hunter, which I examined, and found it to have all the parts peculiar to the female of that bird. This specimen is still preserved in Dr. Hunter's museum. Dr. Pitcairn having received a pheasant of this kind from Sir Thomas Harris, showed it as a curiosity to Sir Joseph Banks and Dr. Solander. I, happening to be then present, was desired to examine the bird, and the following was the result of my examination:—I found the parts of generation to be truly female, they being as perfect as in any hen pheasant that is not in the least prepared for laying eggs, and having both the ovary and oviduct. As the observations hitherto made have been principally upon birds found wild, little of their history can be known; but from what took place in a hen pheasant in the possession of a friend of Sir Joseph Banks, it appears probable that this change of character takes place at an advanced period of the animal's life, and does not grow up with it from the beginning. This lady, who had for some time bred pheasants, and paid particular attention to them, observed that one of the hens, after having produced several broods, moulted, when the succeeding feathers were those of a cock, and that this animal was never afterwards impregnated. Hence it is most probable that all the hen pheasants found wild, having the feathers of a cock, were formerly perfect hens, but have been changed by age, or perhaps by certain constitutional circumstances. Having bought some pheasants from a dealer in birds, among which were several hens, I perceived, the year after, that one of the hens did not lay, and that she began to change her feathers. The year following she had nearly the plumage of the cock, but less brilliant, especially on the head; and it is more than probable that this was an old hen, nearly under circumstances similar to those before described.' The alternative above alluded to has been proved (*Phil. Trans.*, 1827) by Mr. Yarrell, whose dissections demonstrate this change and its causes, and whose observations show that it is not uncommon. He states that certain constitutional circumstances producing this change may and do occur at any period during the life of the fowl, and that they can be produced by artificial means. The same author, in his excellent 'History of British Birds,' now in course of publication, observes that these cock-plumed hens are usually called by sportsmen and gamekeepers 'Mule Pheasants,' a designation which he considers to be correct, since some of our dictionaries show that the term *Mule* is derived from a word which signifies barren, and such hen pheasants are incapable of producing eggs, from derangement of the generative organs; sometimes an original internal defect, sometimes from subsequent disease, and sometimes from old age. He adds that he has seen this disorganisation and its effects among birds in the Gold, Silver, and Common Pheasants; in the Partridge, the Peafowl, the Common Fowl, the Crowned Pigeon, the Kingfisher, and the Common Duck: in the latter species he states that the change, in two instances, went on even to the assumption of the two curled feathers above the tail.

But we must not forget that Blumenbach, in his interesting paper 'De anomalis et vitiosis quibusdam nisus formativi aberrationibus commentatio,' read before the Göttingen Royal Society, in July, 1812, has entered fully and particularly into this subject. The species in which he had known the change of plumage to be observed were *Columba Œnas*, *Phasianus Gallus*, *Colchicus*, and *pictus*, *Pavo cristatus*, *Otis tarda*, *Emberiza paradisea* and *longicauda*, *Pipra rupicola*, and *Anas Boschas*. Alluding to the eggs which have been sold as *Cock's Eggs*, he observes, that to him it seems most probable that such specimens have been laid by hens which had either assumed the plumage of cocks from their youth up, or upon whom the change had come in their old age. Though such phenomena are usually gallinaceous, they are not confined to that family; for he relates that Professor Erhard sent to him an egg laid by a Canary Bird, that sang loudly and excellently, having all the appearance of a cock bird. The egg was one-half less than the usual size, but of the ordinary form and colour. Our limits will not allow us to quote this important memoir further; but we would particularly recommend to the attention of the reader who is studying this branch of physiology, the second, third, and fourth sections, respectively entitled *Fabricæ androgynæ phænomena—Generatio hybrida—Animalia in varietates sic dictas degenerantia*.—(*Commentationes Societatis Regiæ Scientiarum Gottingensis Recentiores, Classis Physicæ*, tom. ii.)

That hen pheasants which have begun to put on the livery of the male are not always incapable of producing eggs, is a fact for which we are indebted to Sir Philip Grey Egerton, Bart., well known for the acuteness of his observations in many departments of natural history. Sir Philip informs us that about four years ago a hen pheasant at Oulton Park, Cheshire, which had nearly assumed the plumage of the cock, laid a nest full of eggs, from which she was driven by the curiosity of persons who came to gaze at so strange a sight. She then laid another nest full of eggs, sat upon them, and hatched them; but the young all died soon after they were excluded. This is a very curious case, and seems to show that though the capacity of producing eggs still remained, the organic defect was sufficient to prevent the production of a healthy offspring.

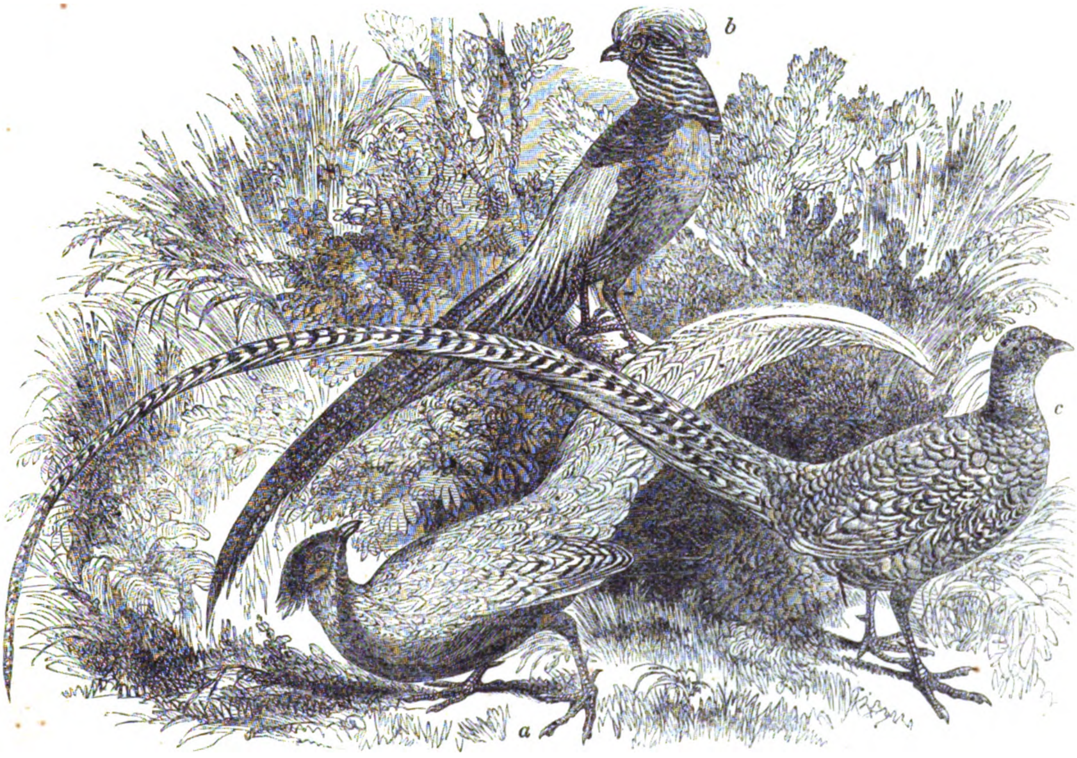
Varieties.—White and Pied: the Ring-necked and Bohemian Pheasants appear to be considered as varieties by Mr. Yarrell; Temminck and Sir W. Jardine consider the former to be completely distinct. The English reader will find the reasons for the latter opinion stated at length in that useful work 'The Naturalist's Library' (*Ornithology*), vol. iii.

HYBRIDS.

Various instances of the common Pheasant breeding with other gallinaceous birds are on record. Edwards has figured a bird supposed to have been produced between a pheasant and a turkey. Three or four of these were discovered in the woods near the house of Henry Seymour, Esq., of Handford, Dorsetshire, and he shot one in October, 1759, the bird which he sent to Edwards. Mr. Yarrell (*British Birds*) observes that he has twice been shown birds that were said to be the produce of the Pheasant and the Guinea Fowl, and the evidence of the plumage was in favour of the statement. We have seen such a bird, and its feathers corroborated the allegation that it had been so produced. In the article BLACK COCK will be found accounts of hybrids between the Cock Pheasant and the Grey Hen. Mr. Eyton, in his valuable work on the *Rarer British Birds*, adds to the account of the hybrid shot near Merrington, figured in that work, and noticed in our article, that the brood to which it belonged consisted of five: one remained in the possession of J. A. Lloyd, Esq., of Leaton Knolls; the other three, with the old Grey Hen, fell victims to a farmer's gun, and were destined to the table. Mr. Eyton further states that he had also seen another specimen killed near Corwen in Merionethshire, then in the collection of Sir Rowland Hill, Bart. Mr. Thompson of Belfast describes (*Magazine of Zoology and Botany*) another hybrid shot at Lochnaw, Wigtonshire, where it had been seen several times on the wing by persons who supposed it to be a wild turkey. In the surrounding plantations Pheasants and Black Grouse were numerous; but this individual, which was preserved for Sir Andrew Agnew, Bart., M.P., was the only one of the kind observed. Mr. John Leadbeater, in 1837, exhibited a hybrid between the Pheasant and Black Grouse, shot near Alnwick, at a meeting of the Zoological Society. This the Duke of Northumberland presented to the British Museum. Dr. Edward Moore (*Magazine of Natural History*, 1837) notices another hybrid of this kind shot near Plymouth by the Rev. Mr. Morshead, and Mr. Yarrell (*British Birds*) records his obligation to the Rev. W. S. Hore, of Stoke near Devonport, for the knowledge of two other specimens killed in Devonshire: one a fine male, in his own collection; the other believed to be at this time in the collection of Dr. Rodd, of Trebartha Hall in Cornwall. To conclude this part of the subject in the words of Mr. Yarrell:—'The last of thirteen examples of hybrids between the Pheasant and Black Grouse here recorded was killed in Northumberland, for a knowledge of which I am indebted to Mr. Selby, of Twizell House. This bird was shot early in December, 1839, by Lord Howick, in a large wood belonging to Earl Grey, a few miles to the east of Felton, and, having been sent to Twizell, I was not only immediately made acquainted with the occurrence, but Mr. Selby has since supplied me with a coloured drawing of the bird, from which the representation at p. 311 was executed.' (*History of British Birds*, May, 1840.)

The union between the common hen and the cock pheasant is by no means rare, as is well known to those whose homesteads border upon pheasant preserves: the produce of this union is called a *Pero*. Many of these, some of them very fine birds, have been kept together in the Gardens of the Zoological Society in the Regent's Park, but they never, as far as we have been able to learn, exhibited any inclination to breed. They are generally considered, as Mr. Yarrell observes, to be unproductive among themselves, all being half-bred; but the case is different when they are paired either with the true pheasant or the common fowl. Edward Fuller, Esq., of Carleton Hall near Saxmundham, has recorded that his gamekeeper had succeeded in rearing two birds from a barn-door hen, having a cross from a pheasant, and a pheasant cock, which he presented to the Zoological Society. On the same evening when these three-quarter-bred pheasants were noticed, hybrids between the Pheasant and Common Fowl, the Common Pheasant and the Silver Pheasant, and the Common Pheasant with the Gold Pheasant, were placed on the Society's table for exhibition. (*Zool. Proc.*, 1836.)

Before we leave the True Pheasants, we must notice some of the magnificent Indian species, which exhibit such a prodigality of splendour and beauty in their plumage as almost realises the birds which we read of in fairy tales. Such are the well-known gorgeous *Gold Pheasant* (*Phasianus pictus*, Linn.—Genus *Thaumalea*, Wagler, *Chrysolophus*, J. E. Gray, *Nycthemerus*, Sw.), the equally well-known delicately pencilled *Silver Pheasant* (*Phasianus Nycthemerus*, Linn.—Genus *Gennæus*, Wagler, *Nycthemerus*, Sw., *Euplocomus*, J. E. Gray), and the noble *Reeves's Pheasant* (*Phasianus veneratus*, Temm.—Genus *Syrmaticus*, Wagler). Of these forms we have endeavoured to give some representation as far as our means will permit.'



a, Silver Pheasant; *b*, Gold Pheasant; *c*, Reeves's Pheasant (Syrmaticus Reevesii)—males.

The two first of these (natives of China) are common in almost every aviary, and there is no reason why they should not thrive well if turned out in our preserves; the second species has, we believe, been so turned out with success: the last is also found in China, but, as it would seem, on the very confines of the empire. It is very rare in Pekin. Dr. Latham's description was taken from Sir John Anstruther's drawings, and from some writing under them in the Persian language it appeared that the bird was called *Doomdurour*, or Long-tail, and it was found on the snowy mountains of Surinagur.

To Mr. Reeves we are indebted for the first individual ever brought alive to Europe. It was a male, and continued to live for some time in the Garden in the Regent's Park. Tail-feathers from it were exhibited to the Society in 1831, measuring each about five feet six inches in length. A second male specimen was also sent to their menagerie by the same liberal donor in 1834. Hybrids were obtained, one of which is, we believe, still alive at the Garden, from one of these birds and the common Pheasant.

Then there are the beautiful *Diard's Pheasant* (*Phasianus versicolor*, Vieill.), which haunts the Japanese woods, and exhibits the manners and habits of our common Pheasant; the rare and elegant *Soemmering's Pheasant* (*Phasianus Soemmeringii*, Temm.), also a native of Japan: but our limits warn us, and we shall proceed to notice some observations of Mr. Vigors, which appear to us to be valuable as conducting the reader to the next form which we shall have to lay before him.

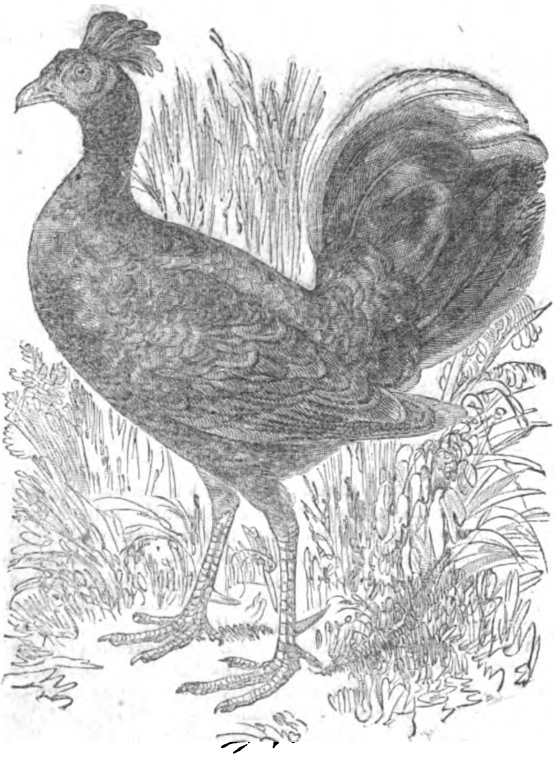
At a meeting of the Zoological Society in 1832, a male and female pheasant were exhibited from the collection, which appeared to be *Phasianus leucomelanos* of Dr. Latham. Mr. Vigors pointed out the difference between this species and *Phasianus albo-cristatus*, which he had described in the first part of the *Proceedings*, and he added that these two species, together with the *Phasianus lineatus* of Dr. Latham, exhibited to the Committee in 1831, and described in the *Proceedings* of that date, as well as the *Fire-backed Pheasant* (*Phasianus ignitus*, Lath.), formed a group among the *Pheasants*, which appeared intermediate between the typical birds of that family and the genus *Gallus*, or *Jungle Fowl*. This group, he observed, distinguished by their crests and by their tails partaking equally of the elevated character of that of the *Jungle Fowl* and the recumbent character of that of the *Pheasant*, had been set apart by MM. Temminck and Cuvier under the name of *Houppifères*, and by the former naturalist under the scientific name of *Euplocamus*.

Euplocamus. (Temm.)

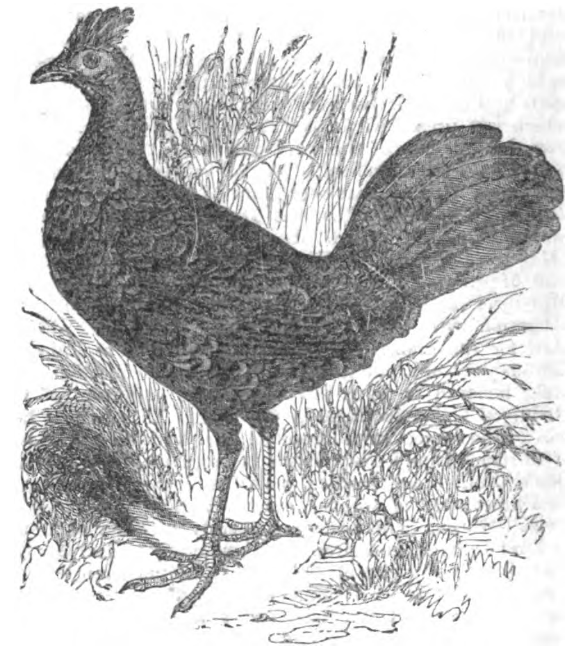
Example, *Euplocamus ignitus*.

Sir George Staunton, in his 'Embassy to China,' first made this highly interesting form known to European zoologists. His host at Batavia had, it appears, a very curious collection in the several departments of natural history. He made presents to his guests of several specimens, and among them was this beautiful pheasant, which was sent to England and described by Dr. Shaw. The tail was mutilated, for which reason the representation in the plate, No. 13 (*Atlas* to Sir George's work), was so conducted as purposely to leave the form of the tail undetermined.

Description.—Length of adult *male* about 2 feet. Skin of the nostrils stretching backwards over the sides of the head behind the eyes and bluish purple. A crest upon the crown of the head composed of naked-shafted feathers expanding at their tips into slender spreading barbs. Head, neck, breast, belly, and upper part of the back, deep chalybean or steel-blueshot black; lower part of the back fiery orange red or flame colour, varying in intensity according to the incidence of the light, and passing like a zone round the body, though more obscure on the abdomen; rump and tail-coverts broad and truncated, brilliant bluish green with a paler bar at the tip. Tail when erect folded in some degree like that of a hen; the middle feathers white, and the outside ones black with green reflections. Legs and feet vermillion, spurred.



Euplocamus ignitus (male)



Euplocamus ignitus (female).

Female, length about 20 inches. Plumage almost entirely rich cinnamon brown; feathers of the upper parts slightly mottled with black; throat white; lower parts of a paler tint than those above, and having the feathers bordered with white. Elongated head-feathers capable of being erected into a crest, but not equal to that of the male. Tail folded. Legs spurless.

Locality, Sumatra.

This is the *Fire-backed Pheasant of Java* ('Atlas' to Staunton's *Account of Lord Macartney's Embassy to China*), *The Macartney Cock* of English authors, *Phasianus ignitus* of Latham.

Gallus. (Brisson.)

Generic Character.—*Bill* moderate, strong, convex above, curved towards the point, naked at the base, and furnished with two pendant and compressed caruncles or wattles. *Head* surmounted with a fleshy crest or comb. *Tarsi* (in the male) furnished with a long and recurved spur: the hind toe only resting on the ground at its tip. *Wings* short and graduated. The fourteen tail-feathers forming two vertical planes with the backs of the feathers towards each other, and so making what may be called a folded tail; the middle feathers longest and recurved.

The ancestors from which our domestic poultry have descended were undoubtedly natives of Asia; but some doubt still hangs over the questions of the precise breed from which they came, and the exact locality where they were found. That fowls were domesticated at a very early period there is no doubt, and both historians and poets speak of the high antiquity of the race. Thus Peisthetærus relates why the cock is called Περσικὸς ὄρνις (the Persian Bird), and how it reigned over that country before Darius and Megabazus. (Aristoph., *Birds*, 483 et seq.)

To the forests and jungles of India we must look for the race in a state of nature; and though the denizens of our farm-yards may be the result of a mixture of many of the species which there inhabit, zoologists in general agree with M. Temminck in thinking that to the *Malay Gigantic Cock* or *Fowl* (*Gallus giganteus*, Temm.) and the *Bankiva Cock* (*Gallus Bankiva*, Temm.) we are chiefly if not entirely indebted for our common poultry.

The domestic cock and hen are the ἀλεκτρυών (Alectryon) and ἀλεκτορίς (Alectoris) of the Greeks; *Gallus* and *Gallina* of the antient Italians; *Gallo* and *Gallina* of the modern Italians; *Haus Hahn* and *Haus Henne* of the Germans; and *Coq* (*Gau, Geau, Gal, Gog*), *Gelline*, and *Poule* of the French.

Bold, ardent, and vigilant, the cock has been always considered the emblem of watchful courage, whilst the hen has been considered a patern of maternal solicitude. In this and other polygamous species, the object to be attained is the effective impregnation of the greatest numbers of females by the most vigorous male. In the cock accordingly the spurs are developed as the sexual organs are matured; and it is principally with these weapons of combat that the battle which is to leave the field in the possession of the strongest is decided. The conqueror in his turn, as the weakness of age comes upon him, yields to a younger and more powerful rival; and thus a numerous, healthy, and stout progeny is secured.

How the domestic cock and hen were introduced into Greece and the south of Europe is not known: upon such occasions of doubt the Phœnicians are usually resorted to; but we are ignorant of proof which can bring home the benefaction to them more than others. We find it early on the Greek and Roman coinage, and upon gems; and it figured in the public shows of those nations. It was dedicated to Apollo, to Mercury, to Æsculapius, and to Mars. Socrates, in his dying moments, reminded his disciples that he 'owed a cock to Æsculapius.' The Rhodian fowls (Martial, iii. 58, above quoted) and those from the Isle of Delos were celebrated for their superiority in fight and their delicacy for the table. The luxurious Roman had his hens fed, perhaps crammed, with meal in the dark. Thus Martial (xiii. 62, 'Gallina Altilis'):—

> 'Pascitur et dulci facilis gallina farina,
> Pascitur et tenebris: ingeniosa gula est.'

Nor was the same gastronomer ignorant of the value of the capon. (Martial, xiii. 63.)

The bird appears to have been in Britain before the invasion of Julius Cæsar, who tells us that the Britons abstained from tasting the hare, the hen, and the goose; though they bred them for their pleasure. This abstinence seems to have originated in superstitious feeling: 'Leporem et gallinam et anserem gustare fas non putant: hæc tamen alunt, animi voluptatisque causa.' (*De Bello Gallico*, lib. v.) The race is now spread all over the civilised world.

M. Lesson asks if it is not remarkable to find the domestic hen, differing in nothing from that of our countries, in all the islands of the South Sea, and among people with whom Europeans have certainly never communicated? Cocks and hens, he tells us, were very common at Oualan for example, and the natives were ignorant that these birds were good to eat. They were found among the Papuans, and among others there was a white variety with all the feathers frizzled.

We now proceed to lay before our readers a sketch of the wild breeds; and first of the *Gigantic Cock*.

This, the *Kulm Cock* of Europeans, often stands considerably more than two feet from the crown of the head to the ground. The comb extends backwards in a line with the eyes, it is thick, a little elevated, rounded upon the top, and has almost the appearance of having been cut off. The wattles of the under mandibles are comparatively small, and the throat is bare. Pale golden-reddish hackles ornament the head, neck, and upper part of the back, and some of these spring before the bare part of the throat. Middle of the back and lesser wing-coverts deep chestnut, the webs of the feathers disunited; pale reddish-yellow long drooping hackles cover the rump and base of the tail, which last is very ample and entirely of a glossy green, of which colour are the wing-coverts; the secondaries and quills are pale reddish-yellow on their outer webs. All the under parts deep glossy blackish green with high reflections; the deep chestnut of the base of the feathers appears occasionally, and gives a mottled and interrupted appearance to those parts. (Jardine principally.)

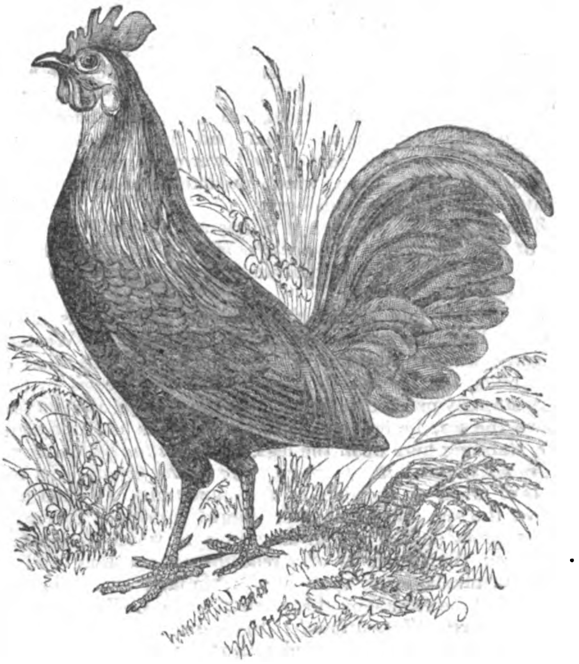
Lieut.-Col. Sykes, in his memoir on the birds found in the Dukhun (Deccan), states that it is only there met with as a domestic bird, and that he has reason to believe that it is not a native of India, but has been introduced by the Mussulmans from Sumatra or Java. The iris, he says, of the real game bird should be whitish or straw-yellow. The colonel landed two cocks and a hen in England in June, 1831; and they bore the winter well. The hen laid freely, and in September, 1832, had reared two broods of chickens. The cock had not the shrill clear pipe of the domestic bird, and his scale of notes appeared to be more limited. A cock in the colonel's possession stood 26 inches to the crown of the head, but they attain a greater height. The length from the tip of the bill to the insertion of the tail, 23 inches. Hen one-third smaller than the male. (*Zool. Proc.*, 1832.)

Bankiva Cock.

Description.—Space round the eyes and throat bare, comb much developed, deeply lobated along the upper ridge, wattles of the lower mandible rather large; long, clear, brilliant, golden orange hackles cover the head, sides of the neck, back, and rump. Upper part of the back below the hackles bluish-black, the middle and lesser wing-coverts rich deep chestnut, with the webs of the feathers disunited; greater coverts steel-blue, secondaries the same, with a broad chestnut border: quills brownish-black, edged with pale reddish-yellow. Tail black, richly glossed with green and blue. Under parts black.

This is the *Coq et Poule Bankiva* of Temminck; *Gallus Bankiva* and *Ayam utan* or *Bronga* (*Linn. Trans.*, xiii.); *Javan Cock* of Latham; and many Bantams resemble it very closely.

Sir W. Jardine states that he has seen three or four specimens of another bird very closely allied to *Gallus Bankiva*, but rather larger, and certainly distinct: they were all from the continent of India.



Gallus Bankiva.

We have also to notice the *Bronzed Cock* (*Gallus æneus*), figured by M. Temminck from a specimen sent from the interior of Sumatra by M. Diard. This is somewhat larger than the *Bankiva Cock*, and its large comb is without dentilations; indeed the edge is quite unbroken; the feathers of the head, neck, and upper part of the back are rather elongated, but not hackles. The *Fork-tailed Cock* (*Gallus furcatus*, Temm.; *Gallus Javanicus*, Horf) has the comb also entire, and the throat is adorned with a single large wattle springing from the centre. The head, neck, and upper part of the back are covered with feathers, which are not hackles, shorter and more rounded than those in the *Bronzed Cock*.

But the species which bears the name of Sonnerat is, in the judgment of that traveller, the probable stock from which our poultry are derived. The general opinion of naturalists is however adverse to that of Sonnerat; and indeed the great difference in the structure of a part of the plumage militates against it; not that it is to be concluded that the bird would not breed with our domestic hen, and produce fertile progeny; on the contrary, there is good reason for believing that such offspring would be capable of continuing the species.

Gallus Sonneratii.

Description. (*Male.*)—Size nearly equal to that of a domestic cock; but the bird is altogether lighter, more graceful, and has a higher bred look about it; comb large, and with an unequal margin, but though this margin is jagged, it is not deeply dentilated; wattles double, depending from the base of the lower mandibles; hackles of the neck and of the wing and tail-coverts dark greyish, with bright golden orange shafts dilating in the centre and towards the tip into a flat horny plate. In some of these feathers the shaft takes an elliptical or oar-like shape; in others it puts on the appearance of a long inverted cone, from the centre of the base of which a battledore-like process arises. The substance and appearance of these plates have been not inaptly compared with the wax-like plates which ornament the wings and tail of the Bohemian Chatterer. [BOMBYCILLA.] The effect produced by this modification of the shafts is singular and beautiful. Feathers of the middle of the back, breast, belly, and thighs deep rich grey, with paler shafts and edges; tail generally rich deep green; the feathers which immediately succeed the hackles are rich purple, with a pale yellow edge; those next in succession are golden-green, with grey edges, and all are glossed with brilliant metallic reflections. Bill, legs, and feet yellow. The living bird presents altogether a rich and striking object, especially when the sun shines on the plumage.

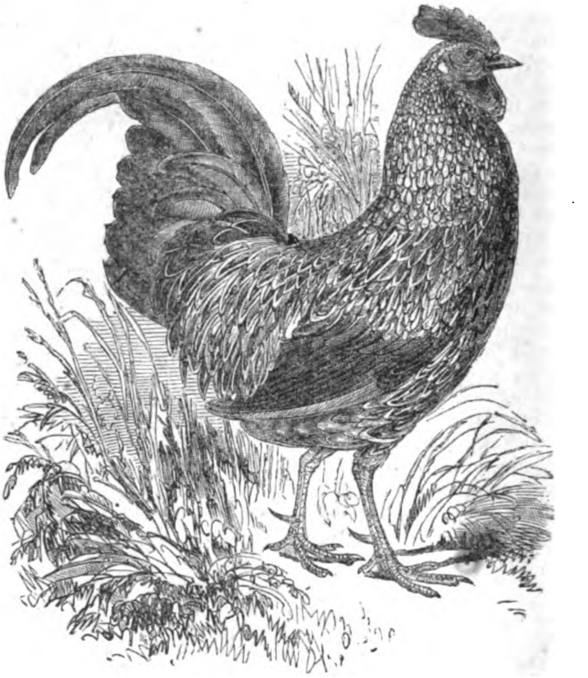
Female less than the cock by about a third, without comb or wattles, but a trace of nakedness round the eye. The plumage (generally) is without the horny structure which distinguishes that of the male. Upper parts uniform brown; neck feathers with dark edges, those of the back and wing-coverts with a pale streak along the shaft, and those of the wings, tail-coverts, and tail waved and mottled with darker pencillings; throat and front of the neck white; feathers of the rest of the lower parts greyish-white, edged with dark brown, which predominates towards the vent. Legs and feet bluish-grey

This is the *Coq sauvage* of Sonnerat; *Coq et Poule Sonnerat* of Temminck; *Sonnerat's Wild Cock* of Latham; *Rahn Komrah* of the Mahrattas; *Jungle Cock* of the English sportsmen in India.

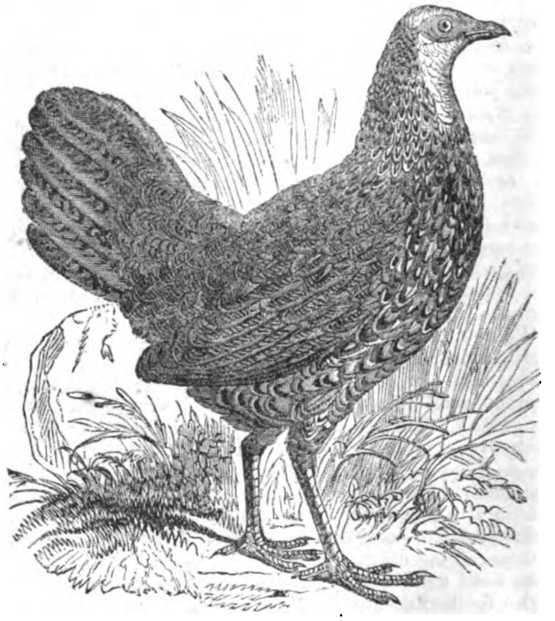
Col. Sykes, in his valuable catalogue, notes this noble bird as being very abundant in the woods of the Western Ghauts, where (and this is well worthy the attention of ornithologists) he says there are either two species or two very strongly marked varieties. In the valleys, at 2000 feet above the sea, he tells us *Sonnerat's* species is found slender, standing high upon the legs, *and with the yellow cartilaginous spots on the feathers, even in the female*. In the belts of wood on the sides of the mountains, at 4000 feet above the sea, there is a short-legged variety. The male has a great deal of red in the plumage, which *Sonnerat's* has not; the female is of a reddish-brown colour, and is without cartilaginous spots at all: 'in fact,' continues the Colonel, 'the female of this variety is the *Gallus Stanleyi* of Mr. Gray's *Illustrations*.' Eggs exactly like those of the domestic fowl in form and colour, but less in size. Col. Sykes shot a hen upon her nest, wherein there were three eggs only, in which the process of incubation had evidently been going on for some days, whence it is concluded that the wild hen sits upon a less number of eggs—*quære tamen*. In the craw and stomach of many birds Col. Sykes found nothing whatever, excepting the seeds of a stone-like hardness called *Job's tears* (*Coix barbata*). The irides are stated by Colonel Sykes to be brownish deep orange, and he says that the crow or call of this species is like that of the *Bantam Cock*. (*Zool. Proc.*, 1832.)

Dr. Latham remarks that this jungle-fowl is by far the boldest and strongest for its size, and that it is anxiously sought after by cock-fighters in Hindustan, who rely on it for victory when pitted against larger game-cocks.

Individuals of this species have been exhibited alive in the garden of the Zoological Society in the Regent's Park.'



Gallus Sonneratii (cock).



Gallus Sonneratii (hen).

But whatever may have been the source or sources from which our domestic poultry sprang, and the probability is that more than one wild race have contributed to improve it, the varieties in a reclaimed state are almost infinite. The Spanish breed, entirely black, grows to a considerable size, and the eggs are remarkable for their volume. The Dorking poultry have long been celebrated, and they are known, principally, by having supernumerary toes. The true Dorkings are purely white, and are much esteemed for the table. Dr. Latham mentions one of this breed that weighed nearly fourteen pounds. Some of the Sussex fowls are very fine.

The fancy breeds are very numerous: among them the Dutch and Polish top-knotted and pencilled breed, of two sorts, known as Gold Spangles and Silver Spangles, are much prized by some amateurs if clean-feathered, and make a very handsome appearance in the poultry-yard. Sir John Sebright brought a dwarf Bantam breed, with unfeathered legs, no top-knots, and gold-spangled and silver-spangled plumage to great perfection, as he did the breeds of most animals in which he took an interest. These clean-legged bantams were further remarkable, when true-bred, for having the tail in the cocks folded like that of a hen, and without the usual recurved drooping feathers; whence they were called hen-cocks. But though without these feathers, which are the usual indications of the common cock, no birds could possess higher courage or a more gallant carriage: we have seen one of these cocks bear himself so haughtily that the back of his head nearly touched the two almost upright feathers of his tail; and both cocks and hens without one foul feather about them. The ordinary bantams have feathered legs and the recurved sickle-like tail-feathers. Colonel Sykes remarks that the supposed species *Gallus Morio* very frequently occurs accidentally in the Dukhun (Deccan), and that, though unsightly, this fowl is very sweet eating. The periosteum of its bones is black, and the comb, wattles, and skin dull purple. *Gallus crispus*, according to Colonel Sykes, occurs accidentally in the Deccan, like the last-mentioned variety. This, generally known as the ***Friesland*** or

UNIVERSIDAD CENTRAL DONACIÓN BIBLIOTECA

Crested Cock, has all the feathers frizzled, or curled, as it were, the wrong way. It occurs also in a domesticated state in Java and Sumatra. The general colour of the plumage is white. Then there is the *Silk-fowl* (*Gallus lanatus*), which M. Temminck is inclined to consider distinct, and which comes from Japan and China. This bird is rather small in size, and the webs of the white feathers, which are silky to the sight and touch, are disunited. The comb and wattles are of a lake-purple colour. The periosteum and skin of this kind are also dark; but the flesh is very white. These silk-fowls make very good nurses, and are easily crossed with the common poultry. The *Rumpless* or *Persian Cock*, or 'Rumkin,' as it was formerly termed, is tailless. Colonel Sykes states that the *domestic fowl* (*Gallus domesticus*, Ray, *Phasianus Gallus cristatus*, Linn.) is so abundant in Deccan, that in parts of the country not much frequented by Europeans he has bought from eight to twelve full-grown fowls for two shillings. Many of the hens, particularly of the villages in the Ghauts, are not, he says, to be distinguished from the wild bird, excepting only in the want of the cartilaginous spot on the wing-coverts.

For an account of the *Hybrids*, see above (p. 60).

The common hen is subject to the assumption of the plumage of the cock, under certain circumstances, as we have already noticed above (p. 60).[*] Whilst on this point we would observe that the pea-hen noticed by John Hunter [Pavonidæ, vol. xvii.] is preserved stuffed in the Museum of the College of Surgeons, as well as the internal parts.

The proper mode of rearing poultry and hatching chickens, both naturally and by artificial heat (hotbeds, steam, &c.), together with the mode of constructing an artificial mother for the young which are so produced, and the method of ordering a poultry-yard generally, will be more properly treated of under the article Poultry, as well as the diseases to which the birds are subject. Of the gapes we have already spoken (ante, p. 59).

Tragopan. (Cuv.)

This is the genus *Ceriornis* of Swainson.

Generic Character.—Head crested on the crown, partly naked (on the cheeks and round the eyes), the naked parts terminating in horn-like caruncles behind the eyes; under the lower mandible and on the forepart of the throat a subpendent composite carunculated wattle. *Tarsi* armed with a blunt spur in the male; unarmed in the female.

Mr. Gould (*Century of Birds from the Himalaya Mountains*) remarks that the genus *Tragopan* appears to take an intermediate station between that of *Meleagris* and the more typical *Phasianidæ*, forming one of the links of a chain connecting these groups of the Rasorial order. The affinity of this genus, he observes, to that of *Meleagris*, is evident in many characters; nor are some wanting which indicate a relationship to *Numida*, and even to *Francolinus*.

Tragopan Satyrus appears to have been the only species originally known. Mr. Gould, in his 'Century,' describes another species, *Tragopan Hastingsii*, and refers to another, which Mr. Gray, of the British Museum, has dedicated to M. Temminck. (*Indian Zoology*.)

Example, *Tragopan Hastingsii*.

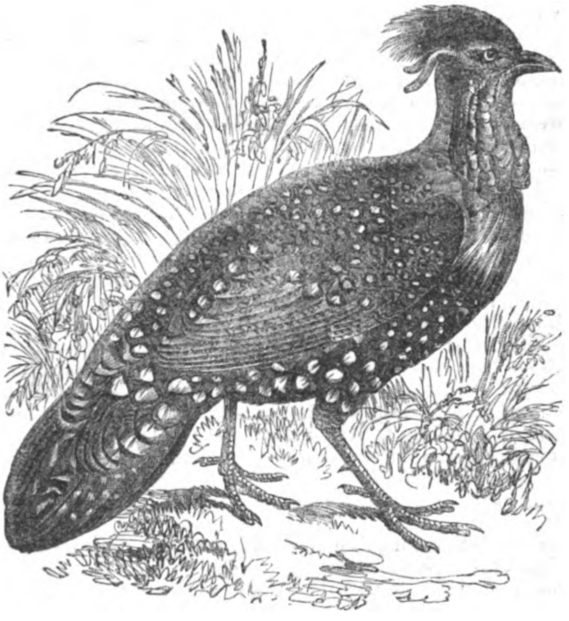
Description.—Head of the *adult male* covered with a pendent crest of feathers, which, as well as the ear-coverts and throat, are black; the neck and shoulders are rich maroon; the chest rich glossy orange red; the naked skin around the eyes is red; the fleshy horns and wattles mingled blue and purple; the upper parts exhibit a mixture of zigzag lines and marks of dark and light brown, with numerous and distinct spots of white; each of the upper tail-coverts ends in a large white eye, bordered on the sides with brown, and tipped with black; the tail deepens till it ends in uniform black; the feathers of the under surface are maroon, largely tipped with black, in the centre of which is a large white spot; the beak is black, the tarsi brown.

In the *young male* the plumage is much less brilliant, the wattles being of a pale flesh-colour, and little developed, as is also the naked skin of the face.

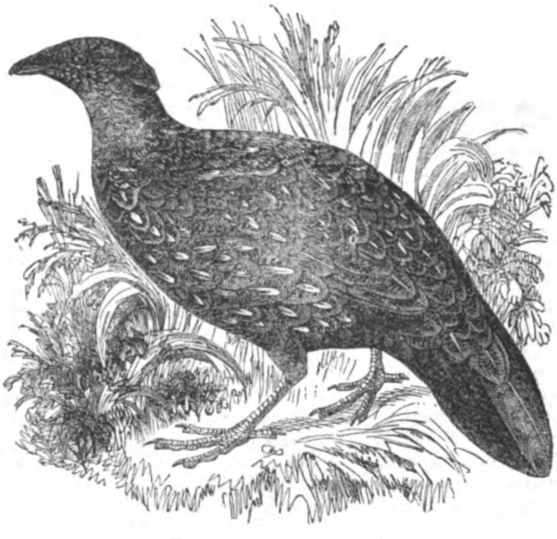
The plumage of the *female* consists of a uniform brown, mottled and barred with mingled lines and dots of various tints, the feathers of the back and chest having a central dash of a lighter colour; the head is crested, with short rounded feathers; the sides of the cheeks are clothed, and there are neither fleshy horns nor wattles. (Gould.)

Mr. Gould observes, that although this species and *T. Satyrus* are closely allied to each other, and doubtless possess similar habits and manners, he is led to believe that their local distribution is somewhat different; at least, he generally receives but one species in a collection from the same quarter; *Tragopan Satyrus* being transmitted from the Nepaulese Hills, while *T. Hastingsii* is sent from the more northern range of the Himalaya. He further well observes that the changes of plumage which birds of this genus, especially *T. Hastingsii*, undergo in passing from youth to maturity (and this is well illustrated in Mr. Gould's beautiful plates), are such as to have caused an apparently erroneous multiplication of species.

Tragopan Satyrus, according to the same author, is an exclusive inhabitant of the colder regions of the mountains, in conjunction with the *Lophophorus*, its proximate relative, feeding on grains and roots, the larvæ of ants, and other insects. [Pavonidæ.]



Tragopan Hastingsii (male).



Tragopan Hastingsii (female).

In conclusion we have to call the reader's attention to the beautiful *Phasianus Staceii* (figured and described by Mr. Gould in his 'Century') as one of the true pheasants; and to *Phasianus Pucrasia* and *Phasianus albo-cristatus*, also there figured. *Phas. Pucrasia* appears to us to lead the way from the true pheasants to the *Lophophori*; and *Ph. albo-cristatus* to be an *Euplocamus*, which, even more immediately than *Euplocamus ignitus*, forms a transition from the genus *Phasianus* to the genus *Gallus*.

---

[*] See also Dr. Butter's paper, 'Memoirs of the Wernerian Society,' vol. iii.

We cannot forbear to add that the *Argus Pheasant* [PAVONIDÆ, vol. xvii., p. 338, et seq.] has been brought alive to this country by that indefatigable collector Hugh Cuming, Esq. It was obtained from Malacca, and is now (June 11, 1840) in good health at the garden of the Zoological Society of London in the Regent's Park. We are not aware of any other instance of a living specimen of this noble bird having been brought home.

PHEIDON, the supreme ruler of Argos, lived in the eighth century before the Christian æra. The Parian marble (No. 31), and several antient writers make him contemporary with Iphitus and Lycurgus; but the statement of Pausanias (vi. 22, § 2), that he celebrated the eighth Olympic games, places him in B.C. 748, which date is also supported by the testimony of Ephorus (apud Strab., viii., p. 358), that he was in the tenth generation from Temenus. Pheidon is usually called tyrant of Argos, but he was in fact the hereditary king. He appears to have obtained the name of tyrant on account of having made himself absolute. (Aristot., *Rep.*, v. 8, § 4.) Pheidon was an active and enterprising prince; and while Sparta was weakened by her wars with the Messenians, he greatly extended the dominions of Argos, and appears to have acquired possession of the whole eastern coast of Laconica as far as Cape Malea, and of the island of Cythera, which, as we learn from Herodotus (i. 82), once belonged to Argos. He attacked the towns which were said to have been taken by Hercules, and claimed the right of presiding over all the festivals which Hercules had instituted. On this ground he deprived the Eleans of their presidency of the Olympic games, which he presided over in conjunction with the Pisæans. (Strabo, viii. 358; Paus., vi. 22, § 2.) But his usurpation united the Eleans and Lacedæmonians against him, and thus led to his overthrow.

Pheidon is said to have invented weights and measures, which bore his name (Strabo, viii. 376; Plin., *Hist. Nat.*, vii. 56; Pollux, x. 179), and is also stated by most antient writers to have been the first person to coin silver money, though, according to Herodotus (i. 94), the Lydians were the first people who put a stamp upon gold and silver.

(Clinton, *Fasti Hellenici*, vol. i., appendix 1; Müller, *Æginetica*, p. 51-63; *Dorians*, vol. i., p. 177-180, translation.)

PHE'NE, Savigny's generic name for the *Lämmergeyer* (*Gypaëtus barbatus* of Storr). Savigny's name is a restoration from Aristotle and the Greek writers on natural history; but the form is known to zoologists under the title attached to it by Ray, viz. *Gypaëtus*. [VULTURIDÆ.]

PHERE'CRATES (Φερεκράτης), a writer of the old comedy, was contemporary with Plato, Aristophanes, Phrynichus, and Eupolis. (Suidas, *Plato.*) His play, called the 'Countrymen' (Ἄγριοι), was represented B.C. 420. (Athen., v., p. 218, d; Plato, *Protag.*, c. 47, p. 327 d.) He wrote seventeen comedies (Suidas, *Pherecrates*), of which a few fragments remain, which have been published, together with those of Eupolis, by Runkel, Leip., 1829. Pherecrates is only mentioned once by Aristophanes (*Lysist.*, 158). He invented a particular kind of metre, which has been called from him the Pherecratic.

PHERECY'DES (Φερεκύδης). There were two Greek writers of this name, the philosopher and the historian, who are frequently confounded, as in Lucian, *Macrob.*, c. 22; Clem., *Strom.*, v., p. 567, c.; Euseb., *Chron. ad Olymp.*, 59, 4.

PHERECYDES, the philosopher, was a native of Syros. His father's name was Babis, and he was born, according to Suidas (*Pherecydes*), in the 45th Olympiad, that is, about B.C. 600. Diogenes Laertius informs us (i. 121) that he flourished in the 59th Olympiad, that is, about B.C. 544; which date agrees with the account of Cicero, who says (*Tusc.*, i. 16) that he was contemporary with Servius Tullius. He is said by some writers to have obtained his knowledge from the sacred books of the Phœnicians or from Egypt, and by others to have been a disciple of Pittacus. (Diog. Laert., i. 116.) He taught Pythagoras (Suidas; Cic., *Tusc.*, i. 16; *De Div.*, i. 50), and appears to have had a considerable acquaintance with natural science. (Diog. Laert., i. 116.) He is said by Cicero (*Tusc.*, i. 16) to have taught the immortality of the soul. According to Suidas, one of his works was entitled 'Ἑπτάμυχος, or the 'Seven Secrets,' and another Θεολογία, which gave an account of the generation and succession of the gods. Theopompus says (apud Diog. Laert., i. 116) that Pherecydes was the first among the Greeks who wrote on the nature of the gods.

There are no particulars of the life of Pherecydes worth recording. His death is variously related: some writers say that he died in the territory of Magnesia in Asia Minor; some, that he threw himself down from the Corycian rock above Delphi; and others, that he died in Delos.

PHERECYDES, the historian, was contemporary with Herodotus, and flourished betweeen B.C. 480 and 456. Suidas mentions two historians of this name, and says that one was born at Athens and the other at Leros; but Vossius (*De Hist. Gr.*, iv. 4) has shown that they are the same person. It appears probable that Pherecydes was born at Leros, and afterwards settled at Athens, whence the mistake of Suidas arose. The work of Pherecydes, which is often quoted by the Scholiasts and by Apollodorus, was a mythological history in ten or twelve books; but it also included events subsequent to the mythological period, as the Scythian invasion of Darius (Clem., *Strom.*, v., p. 567, c.), and the Ionic migration led by the sons of Cadmus (Strabo, xiv., p. 632). Compare Clinton's *Fast. Hell.*, vol. ii., p. 372.

The fragments of Pherecydes have been published by Sturz under the title of 'Pherecydis Fragmenta, e variis scriptoribus collegit, emendavit, commentationem de Pherecyde utroque, et historico et philosopho præmisit, &c.,' Gerae, 1787; 2nd edition, Lip., 1824.

PHERU'SA, Dr. Leach's name for a genus of the Amphipodous order of *Edriophthalmian Crustaceans*. [EDRIOPHTHALMA.]

The genus *Amphithöe*, which generally precedes *Pherusa* in the systems, has the four anterior feet nearly identical in both sexes, and their penultimate joint, or hand, is ovoïd · in *Pherusa* the hand is filiform.

Example, *Pherusa fucicola*.

Description.—Yellowish ash-colour, or grey-ash varied with red.

Locality.—Coasts of England, where it is rare, and found among the sea-weed.

PHERUSA, a Lamarckian genus of Zoophyta. [POLYPIARIA MEMBRANACEA.]

PHIAL, LEYDEN. [ELECTRICITY.]

PHIBALU'RA, M. Vieillot's name for a genus of *Ampelidæ* (*Fruit-eaters* or *Chatterers*), placed both by Mr Swainson and Mr. G. R. Gray in the subfamily of *Bombycillinæ*, the *Swallow-Chatterers* of the former zoologist. The genera included by both in the subfamily are the same; Mr. Swainson's genera being *Phibalura*, *Bombycilla* [BOMBYCILLA], and *Procnias*, and those of Mr. Gray *Phibalura*, *Bombycilla*, and *Tersa*, Vieill., the latter being the *Procnias* of Illiger and others.

Generic Character.—*Bill* remarkably short, but rather strong; culmen arched; *Nostrils* concealed; *Gape* enormous; the sides smooth. *Feet* pale; anterior scales transverse; lateral scales minute, reticulate. Tail lengthened, deeply forked. (Sw.)

Example, *Phibalura cristata*.

Description.—Total length 9 inches, of which the tail occupies 4½ inches. Bill whitish and remarkably short, measuring only 3 lines from the nostrils to the tip, but three-quarters of an inch from the angle of the mouth, which opens just under the eye. Plumage singularly variegated. Crown of the head furnished with a crest, which, when not elevated, is scarcely seen, and appears a deep glossy black mixed with grey and rufous; but, when erected, is very conspicuous, all the feathers being bright rufous, tipped more or less with black; upper sides of the head grey, the lower part and ears deep black; the neck above greyish white, with blackish transverse lines: the back, scapulars, rump, and tail-covers varied transversely with olive, shining black, and bright yellow, each feather olive at the base, black in the middle, and yellow at the tip. Beneath, the feathers of the chin and part of the throat are somewhat lengthened, semi-setaceous, and of a bright yellow; the neck and breast white, with two transverse lines of deep black on each feather; these lines diminish, and are broken into spots on the body, and nearly disappear on the vent: the edges of the feathers are tipped with yellow, and this colour increases downwards on the vent and tail-covers, which latter are entirely yellow. The wings, 4 inches long, are uniform deep black, with a blue gloss, much pointed, and calculated for rapid flight. Tail the same colour, the exterior basal margins olive; all the feathers narrow, pointed, and gradually lengthening; the feet pale yellow, and three-quarters of an inch from the knee to the claws, the three foremost of which are equally connected together (though slightly) nearly as far as the first joint; outer and inner toes equal, and rather shorter than the hind-toe; claws slender and much compressed. (Sw.)

Observations.—Nostrils not covered by a membrane, open obliquely and ovately round, with a narrow rim round the margin: first and third quills of equal length, and shorter than the second, which is longest. (Sw.)

Locality.—South America. A beautiful figure accompanies Mr. Swainson's description in the *Zoological Illustrations*, first series.

PHI'DIAS, one of the most celebrated artists of antiquity, was a native of Athens. His father's name was Charmidas. The exact time of his birth is not known, but, as far as can be judged from the ascertained dates of some of his works, it seems to be generally admitted that it must have occurred between the seventieth and seventy-third Olympiads, that is, from 490 to 480 B.C. It is said that in early life Phidias practised painting, but there is no authority for his having followed it as a profession, and if he ever practised it, as it is probable he did, from some of his family being painters, he doubtless soon relinquished it for the sister art of sculpture, in which he afterwards became so eminent. Phidias, according to antient writers, had two masters, Hippias, and Eladas, Geladas, or Ageladas. Hippias is mentioned only by one author (Dion. Chrysostom., *Orat.*, lv.), and the modern writers on the life of Phidias seem disposed to reject that testimony. (Emeric David, Müller, Sillig, and others.) Ageladas was one of the most distinguished artists of the age. He was a native of Argos.

The times in which Phidias lived were peculiarly favourable to the development of his genius and talents, and his ability must have been shown at a very early age, as it appears he was extensively employed upon great public works, even during the administration of Cimon. Afterwards, when Pericles attained the supreme power in Athens, Phidias seems to have been consulted on all occasions in which the embellishment of the city, either by magnificent buildings or by sculptured decorations, was contemplated. 'It was Phidias,' says Plutarch (*Pericles*), 'who had the direction of these works, although great architects and skilful artificers were employed in erecting them.' Among the more remarkable objects upon which his talents were at this time exercised, the temple of Minerva, called the Parthenon, justly claims pre-eminence. No pains and no expense were spared to make this one of the most splendid and perfect monuments of art; and, fortunately, enough exists in the present day, both of its architecture and sculptural decorations, to confirm the high encomiums passed upon it by those who saw it in its perfection. The temple itself was constructed of marble. The architects employed upon it, under the direction and superintendence of Phidias, were Callicrates and Ictinus; but the statue of the goddess within the temple was the work of Phidias himself, and, with the exception of the statue of the Olympian Jupiter, which he made at Elis, was the most celebrated of his performances. Minerva was represented standing. In one hand she held a spear; in the other a statue of Victory. Her helmet, highly decorated, was surmounted by a sphinx. The naked parts of the figure were made of ivory. The eyes were of precious stones, and the drapery throughout was of gold—of which metal, it is said, no less than forty talents' weight was used. We are told that by the advice of Pericles, Phidias so arranged the drapery that it could at any time be removed without injury. This seems to have been suggested by the feeling that the Athenians might possibly desire to ascertain whether the gold was fairly appropriated; and subsequent events proved the wisdom of the counsel. The people, desiring to have all the glory of this work, had a decree passed prohibiting Phidias from inscribing his name on the statue, but he contrived to introduce his own portrait (as an old bald-headed man, hurling a stone) in the representation of the combat of the Athenians and Amazons which decorated the shield. A likeness of Pericles was also introduced in the same composition. The exterior of this temple was likewise enriched with sculpture; the two pediments, the metopes, and the frieze being filled with statues and rilievi, many of them from the hand and all of them executed under the direction of Phidias. Part of these (known now as the Elgin Marbles, from their having been brought to this country by the earl of Elgin) form a portion of our collection of sculpture in the British Museum. [BASSO RILIEVO; ELGIN MARBLES.] Of their merits it is enough to say that the most eminent judges of modern times have added their testimony to that of the antients by bestowing on them the highest commendation. (Quatremère de Quincy, *Lettres de Londres à Canova; Mémoire sur les Ouvrages de Sculpture qui appartenaient au Parthénon*, &c., par M. Visconti; *Report of Select Committee of the House of Commons*, 1815, in which the opinions of West, Lawrence, Flaxman, and Westmacott will be found well worthy the attention of the student and amateur; Müller, *De Parthenonis Fastigio;* and others.) The eminent sculptor Canova, after visiting London, declared, 'that he should have been well repaid for his journey to England had he seen nothing but the Elgin Marbles.'

The enemies of Pericles, with the view of implicating him also in the charge, accused Phidias of having misapplied part of the gold entrusted to him for the statue of Minerva, and desired that he should be brought to trial. The prudent foresight of Pericles saved both Phidias and himself. He immediately ordered the gold to be taken off and weighed before the people. This however was not done, and the accusation of embezzlement fell to the ground. They then declared the sculptor was guilty of sacrilege in having placed his own portrait on the shield of Minerva. Some accounts say he was thrown into prison, and there died by poison; others, that he was banished. Some affirm there was no sentence passed, but that, fearing the consequences of this charge, the sculptor fled from Athens and took refuge in Elis, and that he was employed there to execute a costly statue of the Olympian Jupiter, to be erected in his temple in Altis. This statue was the most renowned of the works of Phidias. It was of colossal dimensions, and was what the antients called *chryselephantine;* that is, composed of gold and ivory. The god was represented seated on his throne. His brows were crowned with a wreath of olive, and he held in his hand a statue of Victory. The accessories and enrichments of the throne, footstool, and pedestal, which were of the highest quality of art, are described by Pausanias (v., 11, 14, 15), Strabo (viii., p. 353. Casaub.), and other antient writers; and in the highly valuable work, by M. Quatremère de Quincy, 'Sur le Jupiter Olympien.'

A tradition connected with this statue is interesting from its exhibiting the importance which the Greeks attached to works of art of high character and merit. Phidias, after the completion of his design, is said to have prayed Jupiter to favour him with some intimation of the divine approbation. A flash of lightning immediately darted into the temple and struck the pavement before him. This was hailed as a proof of the favour of the god, and in commemoration of the event a brazen urn or vase was placed on the spot. Pausanias (v. 11) says that this existed in his time. It is pretended that Phidias was again accused of robbery by the people of Elis, and that he died in prison. There are however strong reasons for thinking that these accusations against Phidias not only are false, but that the accounts of his death and disgrace are not founded on fact. The scholar will find much that is interesting on this subject in some of the works before referred to. To these we would add O. C. Müller, *De Vitâ Phidiæ;* an Essay by Emeric David, entitled *Examen des Inculpations dirigées contre Phidias*, 1817; also an article, by the same, in the *Biographie Universelle* ('Phidias'); in Junius, *Catalogus Artificum*, and in the work of Sillig with the same title. There can be little doubt, from an expression in Aristophanes ('Peace,' 605, etc.), that an *unjust feeling* had been excited against Phidias, though it is not clear whether he fled or was exiled; and it seems highly probable that he died at Elis. Müller, on the other hand, supposes that Phidias executed the Minerva of the Parthenon, and was then *invited* by the people of of Elis to execute for them the statue of Jupiter; that he returned to Athens, and was, after a time, accused by the enemies of Pericles, who threw him into prison, where he died in the 87th Olympiad. The scholiast on Aristophanes ('Peace,' 604) says he died at Elis; it is also said that he was put to death by the people of Elis, but for what reason is not stated, though some say it was to prevent his ever producing a work that should eclipse their statue. An honour which was paid to his memory would go far to disprove the assertion that he suffered the death of a criminal. The care of his master-piece, the statue of the Olympian Jupiter, was entrusted to his family under the title of *Phaidruntai*. His study or workshop near the temple was also preserved with great respect, and in the middle of it an altar was raised, consecrated to all the gods. Pausanias (v. 14) tells us that the Phaidruntai, descendants of Phidias, existed in his time—six hundred years after the erection of the statue of Jupiter.

Phidias has been called the 'sculptor of the gods' (Quintilian, xii. 10) from the grand and sublime character which he threw into his productions. Reference has already been made to his two greatest works, the Minerva of the Parthenon, and the Jupiter at Elis. He also executed much admired statues, some in marble, but chiefly in bronze, of Venus, Apollo, Mercury, an Amazon, &c., &c. (See Pausanias, *passim;* Plin., *Hist. Nat.*, xxxvi.; Lucian, *De Imag.*) His statues of Minerva were numerous: no less than eight or nine are recorded. One of these, the Minerva Areia of the Platæans, was of wood, gilt; with the exception of the extremities, which were made of the marble of Pentelicus. Although Phidias exercised his skill as a sculptor in all the materials which were in general use for the purposes of art, gold, ivory, bronze, marble, and even wood, yet his productions in a mixture of the two former (*chryselephantine* sculpture) appear to have been the most highly esteemed, both from the extensive scale upon which he used such rich materials, and from the great importance of the works to which they were applied. This is a branch of what the antients called *toreutic* art, which seems to mean the union of metal with any other material.

Phidias brought to perfection the grand or sublime style of sculpture. The artists before him are represented as having a hard, stiff, dry manner. Phidias improved upon this by making a more careful selection and use of the finest models in nature. After Phidias a softer style was introduced, in which Praxiteles, and after him Lysippus, were eminent. The age of Phidias is justly considered the grand and golden age of sculpture.

PHIGALIA (*Φιγαλία*), a town of Arcadia, the site of which is supposed now to be occupied by the modern town of Paulizza. Nothing certain is known respecting its foundation.

Phigalia was attacked by the Spartans, and abandoned by its inhabitants, in the second year of the thirtieth Olympiad (659 B.C.), when Miltiades was archon of Athens. The Phigalians consulted the oracle at Delphi, and the Pythia declared that they could only recover possession of their city with the assistance of a chosen band of one hundred Oresthasians, who should all perish in the battle. The prediction was fulfilled. One hundred Oresthasians willingly devoted themselves, and the Phigalians were re-established. Their heroic deliverers were buried in the forum, and funeral games were celebrated annually in their honour. (Pausanias, viii. 39-41.)

PHIGALIAN MARBLES, a series of sculptures in alto-rilievo, preserved in the British Museum, which are so called from having been discovered among the ruins of a temple at the antient Bassæ on Mount Cotylion, not far from the site of Phigalia. The subjects represented in them are the battle of the Centaurs and Lapithæ, which occupies eleven slabs, and that of the Greeks and Amazons, in twelve slabs. The height of each is two feet one inch, and the whole length about 100 feet. These rilievi formed a frieze round the interior of the cella, and were elevated about 22 feet from the ground.

Pausanias (viii. 41), describing the edifice from which these marbles were brought, says, 'After that at Tegea, it may be considered the most beautiful of all the temples of the Peloponnesus.' The roof of the building was of stone. It was dedicated to Apollo Epicurius (or the *Deliverer*), a title conferred upon him because he had delivered the Phigalians from a pestilence.

These sculptures are of various degrees of merit as regards execution; but the composition, expression, and style of art prove that they came from a fine school of design. The evidence of this in the works themselves is confirmed by the history, which has fortunately reached our times, of the temple which they decorated. The name of the architect was Ictinus, the same who, when Phidias was appointed to superintend the various public works carried on at Athens during the administration of Pericles, was associated with Callicrates to erect the temple of Minerva, or the Parthenon; one of the most splendid monuments of the golden age of art. This gives us the proximate date of the execution of the sculptures under consideration. The Parthenon was finished about 437 B.C. The temple of Apollo at Bassæ may therefore be attributed to about the same period.

The quality of the design of these rilievi warrants the assumption that the eminent sculptor who directed the decoration of the former great work of Ictinus may have contributed the advantage of his skill by suggesting the fine compositions of the sculptures for his present undertaking. It is not difficult to discern in them the same sentiment and character which pervade the marbles of the Parthenon. This correspondence is particularly observable in comparing portions of the Phigalian frieze with the metopes of that building: see *figs.* 1 and 2 (Phigalian Marbles), and *figs.* 6 and 7 (Metopes of the Parthenon), where the same subject,

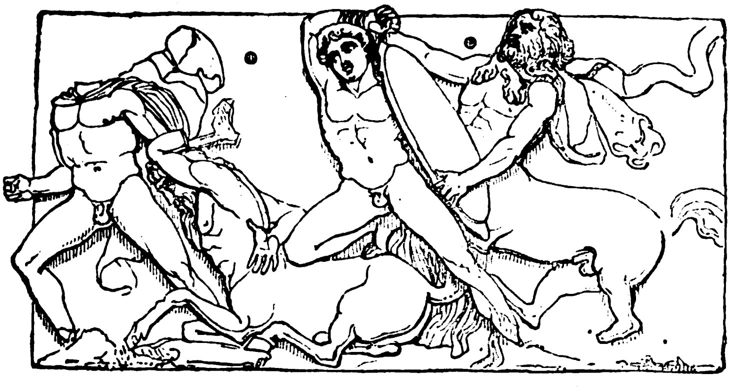

Fig. 2.

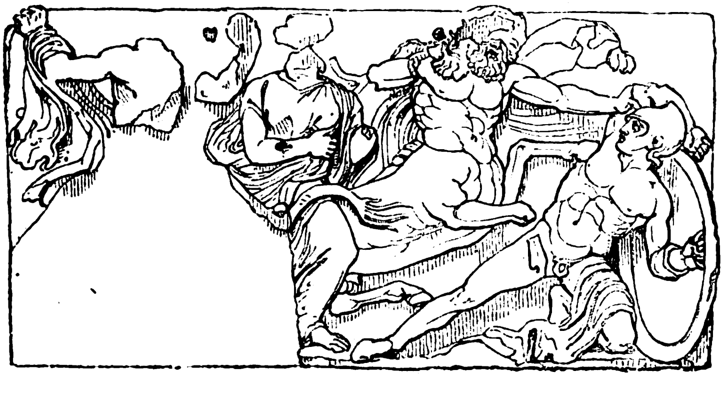

Fig. 3.

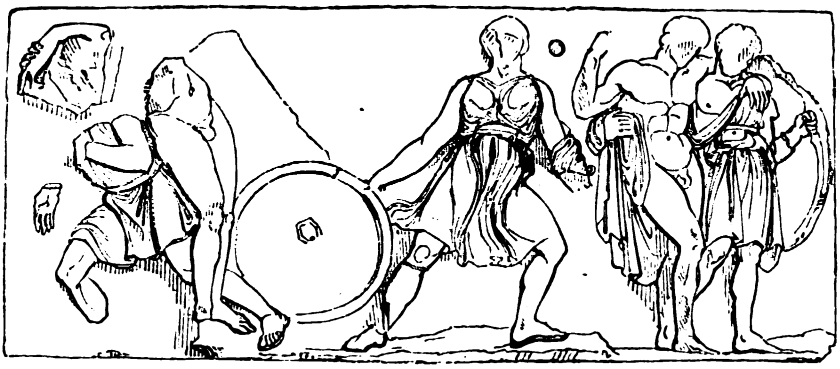

Fig. 4.

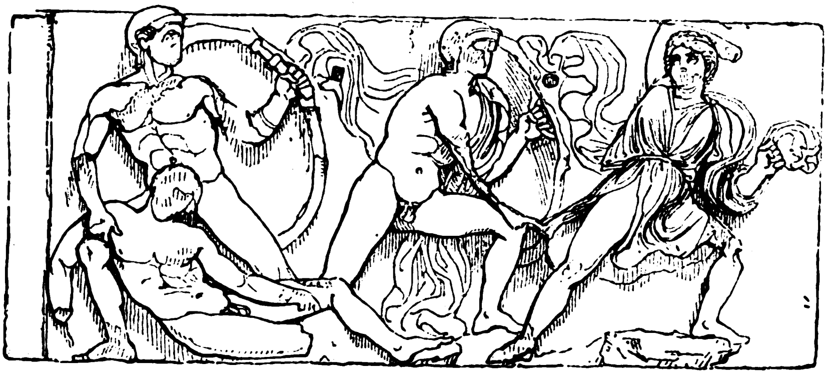

Fig. 5.

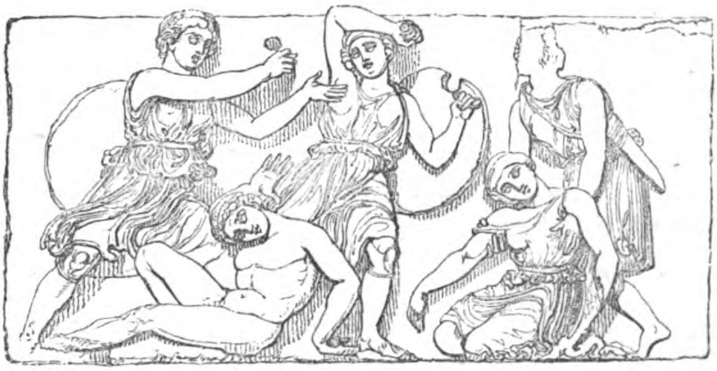

Fig. 6.

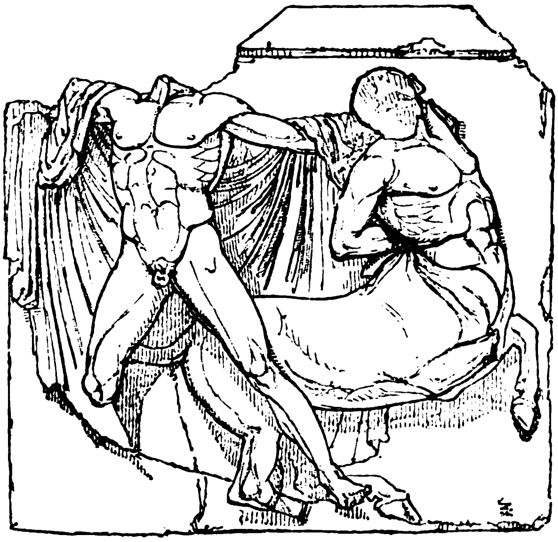

Fig. 7.

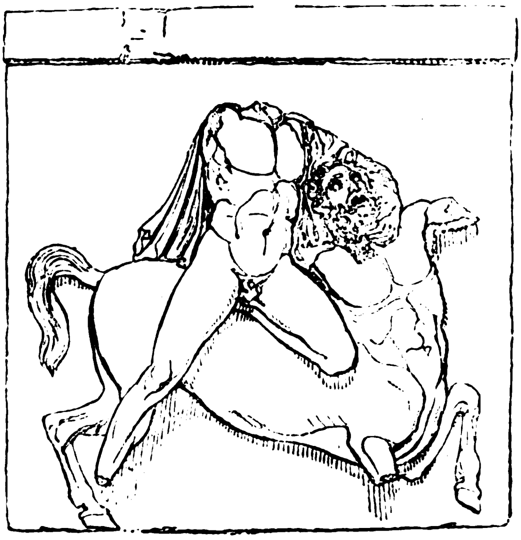
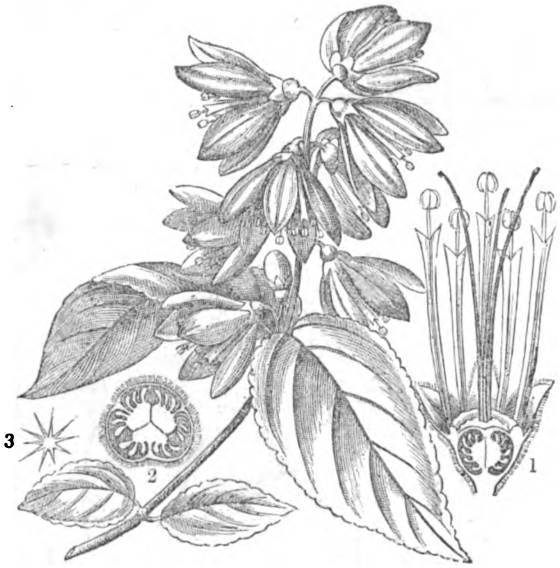


the battle of the Centaurs and Lapithæ, is represented. The same may be remarked with respect to other parts of this fine series, whether it be considered for the energy displayed in violent action (*figs.* 1, 2, and 4), for grace and tenderness where gentler expression is to be conveyed (*figs.* 3 and 5), for playful flow of lines (as in groups in *figs.* 3 and 4), or for the just balancing of parts as the means of producing an harmonious whole. Throughout there is the stamp of careful thought, and evidence of an intimate knowledge of art, combined with a free and bold style. Among the excellencies of *treatment*, as it is technically called, the value and quality of flesh and drapery, in contrast, are finely exhibited in parts of *figs*. 3 and 4. The few specimens here chosen for illustration are sufficient to show the claim these marbles have to our admiration as compositions. The difference alluded to in the merit of the execution may probably be owing to the working out of the general design having been entrusted either to pupils or to various and inferior artists, the idea and the compositions alone being furnished by the master-mind.

These interesting specimens of Greek sculpture were discovered in the year 1812. They were purchased for the British Museum in 1814, and arrived in England in the following year. The slabs were found, with two or three exceptions, lying on the floor or pavement of the temple, under the identical places they had originally occupied. They were much mutilated, both from the injury they had sustained from their own weight in falling, and from the heavy masses of the building which had fallen on them. They have been put together with great care, the pieces being secured by copper bolts; but in no instance has their integrity been impaired by restorations. For detailed descriptions of these marbles, the reader is referred to the elaborate work of Baron von Stackelberg, 'Der Apollotempel zu Bassæ in Arcadien,' &c., Rome, 1826; also to Part IV. of 'Description of the Antient Marbles in the British Museum;' and to the 'Elgin Marbles,' published under the superintendence of the Society for the Diffusion of Useful Knowledge.

PHILADELPHA'CEÆ form a small natural order of exogenous polypetalous plants, with an inferior ovary, the principal genus being that after which the order is named. [PHILADELPHUS.] The species are American, European, and Asiatic shrubs of temperate climates, with opposite leaves, distinct styles, and capsular fruit, containing a large number of minute seeds. Their nearest affinity is, on the one hand, with Myrtaceæ, from which they differ in having separate styles, dotless leaves, and albuminous seeds, and on the other with Saxifragaceæ, from which their strictly inferior fruit, opposite leaves, and parallel styles sufficiently distinguish them. Many of the species, especially in the genus Deutzia, are clothed with beautiful stellate hairs, which form excellent opaque objects for examination with the microscope.



Deutzia scabra.

1, a vertical section of a flower deprived of petals; 2, a transverse section of the ovary; 3, one of the stellate hairs.

PHILADE'LPHIA, formerly the capital of the state of Pennsylvania, in the United States of North America, is situated in the county of Philadelphia, in 39° 57′ N. lat. and 75° 10′ W. long. With the exception of New York, it is the largest city in the United States. The population in 1810 was 96,664; in 1820, 119,325; in 1830, 167,811; and may therefore be now (1840) estimated at upwards of 200,000.

Philadelphia is about 120 miles from the Atlantic, following the course of the Delaware, and about 55 miles from it in a straight line. It lies immediately above the junction of the Schuylkill with the Delaware, and occupies the space, about two miles in width, between the two rivers. The city is about four miles in length; the streets which run north and south, parallel with the rivers, are called First Street, Second Street, and so on, except Broad Street and Schuylkill Street. These streets are crossed at right angles by others which run from east to west, and which are almost all named after trees, as Chestnut Street, Walnut Street, &c. The squares thus formed are subdivided by other streets still smaller and by alleys. The streets are paved with stones; the foot-pavements are of brick, defended by curb-stones. Most of the principal streets have rows of locust and other trees, which afford a delightful shade in the summer. The houses are generally of brick, but many of them have the outer steps and also the window-sills of white marble. The streets, steps, and windows are kept extremely clean, and the whole city has an air of peculiar neatness. Under the main streets there are sewers, which empty themselves into the Delaware. The city is lighted with gas. There are a few squares. Independence Square is about 270 yards each side. Washington Square is the largest in the city, and is a fashionable promenade.

Of the public buildings of Philadelphia, the old State House is one of the most interesting, though one of the plainest. It is of brick, still of the pristine colour. The Declaration of Independence was read from the steps in front of the building, on the 4th of July, 1776. The District Court for the city and county of Philadelphia is held in the State House.

The United States' Mint was established at Philadelphia by an act of Congress passed April 2, 1792, where it has ever since been continued. It is the only place in the United States where coin is struck. A new building was commenced in 1829 on a large scale. The order is Ionic. It has a front of 122 feet, faced with marble, and consists of a portico of 62 feet, and two wings of 30 feet each.

The Bank of the United States is a splendid edifice, entirely of white marble. The portico is copied from the Parthenon at Athens. The Pennsylvania Bank and that of the late Mr. Girard are much smaller, but the fronts of both are of white marble, and they have a very neat appearance.

The Pennsylvania Hospital was instituted in 1751 by voluntary subscriptions, and opened to the public in 1752; from that year till 1832, as many as 29,616 patients were admitted, of whom 15,293 were paupers; 18,400 were restored to health, and 3188 died in the hospital. The number of lunatics admitted during the same period of eighty years was 3718, of whom 1289 were cured, and 530 died in the hospital. It is calculated that about 1400 patients are admitted annually, of whom three-fourths are paupers, and a large number insane. The mode of treatment of the insane patients is one of uniform mildness, and the most beneficial effects have been found to result from it. The hospital has a library of 7000 volumes. The buildings occupy an entire square, in the middle of which is a a bronze statue of William Penn in the dress he used to wear, the square-cut coat, long waistcoat, and cocked hat.

The House of Refuge occupies a plot of ground 400 feet in length by 230 feet in breadth, enclosed by a stone wall 20 feet high. The main building is 92 feet long by 30 feet deep. It receives all destitute males under 21 and all females under 19. It is a school for the reformation of character, which has been productive of great benefit. About 280 can be accommodated.

The Deaf and Dumb Asylum is built of granite. It is 96½ feet long by 63 feet deep. [DEAF AND DUMB, p. 336.]

The Public Almshouse, with an Infirmary attached to it, is a large pile of building, capable of containing 1600 patients. The average number of patients is about 1000. There are many lunatics in one of the wards, who are treated in the same mild manner as at the House of Refuge.

There are several other benevolent institutions, among which the most important are—the Marine Asylum, which has a front of 386 feet, consisting of a portico of 90 feet and two wings of 148 feet each; the Widows' Asylum; the Orphans' Institution; the Magdalen Institution; the Asylum for the Blind; and the Sunday-school Association. There are also a great number of Benefit Societies, for the support of the members in sickness, who contribute a small sum weekly or monthly.

There are upwards of a hundred places of public worship in Philadelphia, but none of them are distinguished either for architecture or size. In 1833 there were 9 Protestant Episcopal churches, 4 Roman Catholic, 19 Presbyterian, 1 Scotch Presbyterian, 10 Methodist, 3 Reformed Dutch, 6 Baptist, 5 German Lutheran, 6 Quakers, 1 Free Quakers, 1 Covenanters, 2 German Reformed, 2 Universalists, 2 Synagogues, 1 Bible Christian, 1 Mariners, 1 Swedenborgian, 10 Unitarians, 1 Moravian, 1 Menonist, 1 Swedish Lutheran, 1 Mount Zion.

In literary institutions Philadelphia ranks perhaps higher than any other city in the United States. The Philadelphia Library was commenced by Franklin in 1731. The building, which is rather handsome, was erected in 1790. A marble statue of Franklin, executed in Italy, is placed over the front door. The library contains 45,000 volumes. The American Philosophical Society reckons among its members distinguished literary men in all parts of the world. The library contains upwards of 10,000 volumes of scientific works. The American Historical Society has also a high reputation. The Academy of Natural Sciences possesses a library consisting of upwards of 6000 volumes. The Philadelphia Athenæum, established in 1814, has a library of about 6000 volumes, and a reading-room in which 70 or 80 newspapers of the United States, as well as English, French, and other foreign journals, may be seen. Peale's Museum has an excellent collection of stuffed quadrupeds and birds, and possesses the most perfect specimen of a mastodon in the world; it is nearly complete, and so large that the skeleton of an elephant placed by its side appears small. [MASTODON, p. 5.]

The University of Pennsylvania is distinguished for its medical school. The new halls, built in 1830, are spacious and handsome. The Jefferson Medical College has also a spacious hall. The Pennsylvania Academy of Fine Arts has a handsome rotunda with a dome. There are several galleries of paintings and statues, which include sculptures by Canova and Chantrev, as well as pictures by the best masters.

The first newspaper published in Philadelphia, entitled 'The American Weekly Mercury,' was printed on a half sheet of pot paper, bearing date December 22, 1719. The second newspaper was commenced in 1728; its title was 'The Universal Instructor in all the Arts and Sciences, and Pennsylvania Gazette.' Before the end of the first year it fell into the hands of Franklin, who was long connected with it as joint or sole proprietor. This paper, under the abridged title of 'The Pennsylvania Gazette,' was continued till within the last fifteen years, having been for a considerable time the oldest newspaper in the United States. There were eight daily newspapers published in Philadelphia, as early as 1807, and we believe the same number still continues. The weekly newspapers vary from 15 to 20. There are 8 or 10 monthly publications, and 4 quarterly.

There are three theatres in Philadelphia; the one in Arch Street is a handsome building, with the front and columns of white marble.

The markets are admirable, particularly one long range in High Street, which is a pattern of perfect cleanliness and neatness.

There are four prisons. The system of solitary confinement was commenced in the Eastern Penitentiary, a building with lofty castellated walls and towers, loop-holed windows, portcullis, and ponderous iron-studded gates; but a new prison has been built which is more suitable for the purpose. The centre is a rotunda, which is used as a watch-room. From this run long passages so contrived that, by means of echoes, every sound may be heard from the most distant part; the cells are on each side of these passages, and are so separated that communication between the inmates is impossible. Each cell is eight feet wide, twelve feet long, and sixteen feet high. Outside the cell is a yard eight feet wide and twenty feet long, surrounded by a high wall, where the prisoner is permitted to walk. From the passages, through small openings, everything that is passing in the cells may be seen. The prisoners are kept employed, but are never permitted to leave the cell or yard till the term of imprisonment has expired, which may continue for years. It has been stated that a prisoner, once released, has never exposed himself to the risk of being committed a second time to the walls of this prison, which, if not strictly true, is perhaps very nearly so. For an account of the mode of treatment and its results, see Miss Martineau's 'Retrospect of Western Travel,' vol. i.

The works for supplying Philadelphia with water are at Fair Mount, near the city, on the eastern bank of the Schuylkill. The projects for supplying the city with water by means of steam-engines having failed, after having been persevered in at an enormous expense for upwards of twenty years, in 1819 the present simple and efficient machinery was commenced. A dam, 1500 feet long, was thrown in a sloping direction across the Schuylkill, so as to be less exposed to the force of the current. There are eight water-wheels, which can raise nearly seven millions of gallons a day into the reservoirs on the summit of a hill 100 feet above the level of the river and 50 above the highest part of the city. The reservoirs can contain 20 millions of gallons. The water is conveyed to the city in pipes. The expense is very trifling, and the supply far beyond what either is or is ever likely to be required.

A wooden bridge of a single arch, of the large span of 340 feet, crosses the Schuylkill near the waterworks. There is a second wooden bridge, about a mile lower down, which consists of three arches supported on stone piers.

The fire-engine establishment is worthy of the highest admiration. There are thirty engine companies and sixteen hose companies, which latter supply the fire-engines with water. The firemen consist generally of young merchants and tradesmen, and are all volunteers. Each member pays a certain sum on his admission, and a small annual subscription; and a fine is imposed upon any member who attends without his waterproof dress. The institution is kept up with an enthusiastic public spirit, and fires are extinguished with a promptitude which raises the astonishment of all strangers who happen to witness an instance. About 5000 dollars are annually distributed to the different companies from the city funds.

The manufactures of Philadelphia are considerable, especially the warping-mills; there are two shot-towers, and there are manufactures of nails, leather, hardware, &c. A great trade is carried on up the Schuylkill and Lehigh, in conveying the produce of the coal-mines, one hundred miles distant, though the coal in summer is seldom under seven dollars a ton, and in winter as high as eleven dollars. It has almost superseded the use of wood. The coal is chiefly anthracite; it is hard and shining, throws out little smoke, does not blaze, and requires bituminous coal to be mixed with it, which is generally imported from Liverpool.

The municipal government of the city proper is vested in a mayor, a recorder, fifteen aldermen, a select council, and a common council. The recorder and aldermen are appointed by the governor of the state, and hold their offices during good behaviour. The mayor was chosen annually by the two councils from among the aldermen till April 10, 1826, when the legislature passed an act authorising the councils to elect him from the body of the citizens. The members of the two councils are chosen annually. They serve gratuitously, sit in separate chambers, and each body has a negative on the legislative acts of the other. The mayor, recorder, and aldermen, or any four of them, of whom the mayor or recorder must be one, constitute the mayor's court. The district court of the city and county of Philadelphia has three judges, one of whom is the president. Each judge has a salary of 2000 dollars a year.

The city proper sends seven representatives and two senators to the state legislature.

Stephen Girard, a Frenchman, who from a humble origin became a banker in Philadelphia, left nearly the whole of his large property towards beautifying Philadelphia and New Orleans, and to establish a college in the former city which should accommodate at least 300 scholars. He bequeathed two millions of dollars for building and establishing the college, the income of so much of it as remained unexpended to be employed in maintaining as many poor orphans of white parents as it was adequate to. The buildings of the Girard College were commenced some time since, and are now probably nearly completed. The whole of the buildings are of white marble.

The river Delaware, in front of the city, is about a mile wide, but the width is contracted by an island, which extends nearly the whole length of the city, and somewhat impedes the navigation. Both the Delaware and the Schuylkill are frozen over during the winter months, which renders Philadelphia, as a harbour, inferior to New York. A portion of the navy of the United States is stationed at the southern extremity of the city, and ships of the largest size are built. The Delaware is navigable for steam-boats and small vessels as high as Trenton.

The following is a statement of the number and tonnage of vessels, with the value of their cargoes, which arrived at and departed from Philadelphia in the year 1837:—

COUNTRIES.	ARRIVED.			DEPARTED.		
	Ships.	Tons.	Value of Cargoes.	Ships.	Tons.	Value of Cargoes.
			£.			£.

Of the 53 British vessels above mentioned, 3 were from Liverpool, with cargoes valued at 8600*l.*, consisting of iron, salt, coals, &c.; 2 from Bristol, with cargoes valued at 14,105*l.*, consisting of railroad-iron, iron for other purposes, glass, copper, &c.; 9 from Londonderry, with cargoes valued at 3373*l.*, consisting of salt and provisions; 19 from St. John's, New Brunswick, with cargoes valued at 2064*l.*, consisting of salt, plaster, fish, &c., and 20 vessels were freighted back to St. John's with provisions valued at 16,468*l.* The rest were generally single vessels from various places.

Philadelphia was founded by William Penn in 1682. On the 5th of September, 1774, the members of the first Congress assembled at Philadelphia, where they adopted the 'Declaration of Rights,' which may be regarded as the preface to the 'Declaration of Independence,' which was proclaimed at Philadelphia in April, 1776. Congress continued to sit at Philadelphia till the close of the autumn in the same year, when the approach of the British compelled them to retire to Baltimore. The British forces obtained possession of the city on the 26th of September, 1777, and occupied it till the 18th of the following June. The city remained uninjured during the remainder of the war. It was the seat of the federal government till the year 1800, and the capital of Pennsylvania till 1799.

(Arfwedson's *United States and Canada;* Coke's *Subaltern's Furlough: Encyclopædia Americana.*)

PHILADELPHI'A. [LYDIA.]

PHILADELPHUS, a genus of plants of the natural family of Philadelphaceæ, which is also the name of a tree, now unknown, mentioned by Athenæus, but was applied to the present genus by Bauhin. Philadelphus is characterised by having a calyx with an obovato-turbinate tube and a 4-5 partite limb. Petals vary in number from 4-5. Stamens, 20-40, free, are shorter than the petals. Styles 4-5 united together, or more or less distinct. Stigmas 4-5, oblong or linear, generally distinct. Capsule 4-5-celled, many-seeded. Seeds dust-like, enclosed in a membranous aril, oblong, and fringed at one end.

The plants consist of shrubs with white pedicillate flowers arranged in a corymbose cyme, in a panicle-like manner, or sometimes in the axils of their leaves, supported by bracts.

The greatest number of species are indigenous in North America, whence they have been introduced into the shrubberies of this country, to which they form a highly ornamental addition. A species has also been discovered in the Himalayas, at elevations of 6000 and 7000 feet, of which there are two varieties, sometimes considered distinct species, P. tomentosus being apparently only a more advanced state of P. triflorus. The best known species however is *P. coronarius*, commonly called Syringa, which is so easy of culture, and found in most gardens. It is supposed to be a native of the south of Europe, but it has hardly ever been found in a wild state, and even in these few cases it may have escaped from cultivation. As one species has been found in the Himalayas, there is no reason why other species should not exist still farther to the north-west, as in the Hindoo-koosh, and that the Syringa may be found to be one of those plants which was in early times introduced from some part of the Persian region of Botanists into the south of Europe.

PHILA'RETUS (Φιλάρετος), the reputed author of a short treatise 'De Pulsibus,' which is written in Greek, but of which only a Latin translation has hitherto been published. Nothing is known about his life, nor the time when he lived; nor is it even certain that he is the author of the work in question, as it is sometimes attributed to Philotheus and sometimes to Theophilus Protospatharius. It was written (as the author tells us) because he thought all former writers on the subject were either too superficial and inaccurate or too prolix; but it is not of much value, and seldom if ever ventures to differ from Galen. It consists of ten chapters, and was translated by Albanus Torinus, and published, Basil., 1533, 8vo. An older and barbarous translation is inserted in the various editions of the curious old collection of medical works called 'Articella.' The translation by Albanus Torinus is to be found also in the second volume of the 'Medicæ Artis Principes,' by H. Stephens, Paris, 1567, fol.

PHI'LEDON, Cuvier's name for a genus of *Meliphagidæ*. [MELIPHAGIDÆ, vol. xv., p. 82.]

Of this form, Mr. Swainson, in his 'Classification of Birds,' vol. ii., remarks that the head is nearly bare of feathers, and the neck surrounded with a ruff somewhat similar to that of the Vultures. Their size is nearly equal to that of a jay, and the claws are strong and acute. The same zoologist further observes, that as they are said to chase other birds of a small size, one would almost imagine they represented the rapacious order.

Mr. G. R. Gray quotes as the synonyms of his genus, *Meliornis Certhica*, Lath., *Meliphaga* (Lew.), V. and H.; and *Philedon*, Cuv., with *Meliornis Novæ Hollandiæ* (Vieill., *Ois. d'Or.*, pl. 57), *M. Balgonera*, Steph., as the type. (*List of the Genera of Birds*, 1840.)

PHILE'MON, Vieillot's name for a genus of birds (*Anthrochæra*, V. and H., *Merops*, Lath.) placed by Mr. G. R. Gray in his subfamily *Meliphaginæ*, which consists of the genera *Meliornis* [PHILEDON]; *Prosthemadera*, G. R. Gray (*Merops*, Lath., *Anthrochæra*, V. and H., *Philemon*, Vieill., *Sturnus*, Daud.—type *P. cincinnata*, Levaill., *Ois. d'Afr.*, pl. 92); *Meliphaga*, Lew. (*Ptilotis*, Sw., *Philemon*, Vieill., *Certhia*, Lath.); *Anthornis*, G. R. Gray (*Melithreptus*, Vieill., *Anthomyza*, Sw., *Furnarius*, Steph., *Certhia*, Sparr—type *A. melanura*, Sparr, *Mus. Carls.*, t. 5); the genus at the head of this article; *Phyllornis*, Boie (*Turdus*, Gm., *Chloropsis*, Jard. and Selby, *Meliphaga*, Horsf.); *Zanthomyza*, Sw. (*Merops*, Lath., *Meliphaga*, Lew., *Philemon*, Vieill., *Anthochæra*, V. and H.); *Anthochæra*, V. and H. (*Creadion*, Vieill., *Philedon*, Cuv., *Merops*, Lath.); *Acanthogenys*, Gould; *Entomyza*, Sw. (*Gracula*, Lath., *Philemon*, Vieill., *Gymnops*, Cuv., *Entomyzon*, Sw., *Tropidorhynchus*, V. and H.); and *Tropidorhynchus*, V. and H. (*Philedon*, Cuv., *Merops*, Lath.). Of these, *Anthomyza* is employed in entomology.

The other two subfamilies of *Meliphagidæ*, according to Mr. G. R. Gray's arrangement, are the *Myzomelinæ* (subfamily 1) and *Manorhininæ* (subfamily 2).

The *Myzomelinæ* consist of the genera *Myzomela*, V. and H.; *Acanthorhynchus*, Gould; and *Glyciphila*, Sw.

The *Manorhininæ* comprehend the genera *Plectoramphus*, G. R. Gray (*Plectorhyncha*, Gould); *Manorhina*, Vieill.; *Psophades*, V. and H.; *Eidopsarus*, Sw.; *Melithreptus*, Vieill.; and *Entomophila*, Gould.

Plectorhyncha had been already used in ichthyology.

PHILE'MON (Φιλήμων), a writer of the new comedy, was born at Soli in Cilicia, according to Strabo (xv., p. 671), or at Syracuse, according to Suidas (*Philemon*). Philemon began to exhibit comedies a little earlier than Menander, and before the hundred and thirteenth Olympiad, that is, B.C. 328. He lived to the age of ninety-six or ninety-seven (Lucian, *Macrob.*, 25), and died in the reign of the second Antigonus, son of Demetrius; he must consequently have been alive subsequent to B.C. 283. He is said to have written 97 comedies, of which Fabricius, in his 'Bibliotheca Græca' (vol. ii., p. 476, ed. Harles), has preserved the titles of fifty-three. Of these comedies, fragments only have come down to us, which are usually published with those of Menander, of which the best edition is by Meineke, Berl., 1823. It seems possible that some of these plays may exist; at least there is evidence that some if not all of them were in existence in the seventeenth century. (*Journal of Education*, vol. i., p. 188.)

Philemon was the great rival of Menander, and was considered superior to him by many of their contemporaries; but posterity, as Quintilian informs us (*Inst. Orat.*, x. 1., p. 222, ed. Bipont), regarded him as inferior to Menander. From the 'Mercator' of Plautus, and the fragments which remain of his plays, Philemon appears to have closely resembled Menander, of whose style, and of the new comedy in general, an account is given under MENANDER.

The son of Philemon is also said to have written comedies. (*Athen.*, vii., p. 291, E.) Suidas says that they were fifty-four in number

There is extant a grammatical work entitled 'Lexicon Technologicon' (Λεξικὸν τεχνολογικόν), written by a grammarian of the name of Philemon, who probably lived in the twelfth century of the Christian æra. This work is divided into eight books, according to the eight parts of speech, which are respectively treated of in each book. The Greek text was first published by Burney, Lond., 1812, 8vo.; but a more accurate edition, with valuable notes, was published by Osann, Berlin, 1821.

PHILE'MON, EPISTLE TO. Philemon was a man of distinction, if not a presbyter, of the church at Colossæ, and was probably converted from heathenism by St. Paul. Theodoret, who wrote at the beginning of the fifth century, says that in his time Philemon's house was yet standing. He had a slave named Onesimus, who robbed his master and fled to Rome, where he met with St. Paul, a prisoner there, about A.D. 62, and through him he became reformed. St. Paul then wrote the 'Epistle to Philemon,' and sent it to Colossæ by Onesimus, recommending him to the kind consideration of his injured master; stating how sincere was his penitence, how excellent a Christian he was, how much he had won the affection of his spiritual father, and how worthy therefore he was to be regarded henceforth by Philemon as a brother rather than a slave, and adding the expression of confidence in the readiness of Philemon to receive Onesimus even more heartily than he was desired.

The epistle of St. Paul to Philemon furnishes a beautiful specimen of gentleness united with commanding authority, in the style and manner of the writer. The Greek original evinces extraordinary skill in the choice and arrangement of words; so that any reader who has well studied the other Pauline epistles, would conclude this epistle to be undoubtedly St. Paul's. Moreover, there is all the historical evidence that can be required to prove it a canonical book.

Onesimus is said by Jerome and others to have become at length a bishop, but whether of Ephesus, as Grotius thinks, or of some other place, is uncertain.

The Apphia mentioned in the epistle is supposed to have been Philemon's wife, and they are said to have been both stoned to death under Nero. In the calendar of the church of Rome the names of Philemon and Apphia occur as those of saints, as does also the name of Onesimus, the two former being commemorated November 22, the latter February 16.

(Theodoret, *On St. Paul's Epistles*; Fabricius, *Bibliotheca Græca*; Butler's *Lives of the Saints*; Schott's *Isagoge*.)

PHILES, or PHILE (MANUEL), (Μανουὴλ Φιλῆς, or Φιλῆ), a native of Ephesus, to be distinguished (according to Fabricius, *Bibl. Gr.*) from four other persons bearing the same surname. As his work is dedicated to the emperor Michael Palæologus the younger, he must have lived about the beginning of the fourteenth century. He was born of poor parents, came at an early age to Constantinople, became one of the pupils of George Pachymer, and made great progress in literature. He afterwards gave offence to the emperor by some expressions made use of by him in one of his works, called 'Chronographia,' which is no longer extant, and was thrown into prison. He is supposed to have died somewhere about the year 1340. He is known chiefly as the author of a work Περὶ ζώων ἰδιότητος, 'De Animalium Proprietate,' written in a sort of barbarous Greek iambics, called 'versus politici.' (See Is. Vossius, 'De Poematum Cantu et Viribus Rythmi,' Oxon., 8vo., 1673, p. 21, sq.) It is a curious work, but of little or no value to a zoologist, taken almost entirely from Ælian's 'Natural History,' and full of the most absurd fables. It was first published at Venice, 1533, 8vo., Græce, by Arsenius, archbishop of Monembasia (a town on the east coast of Laconia, now called Napoli di Malvasia). An edition was published at Leipzig, 1574, 4to. (or, with a fresh title-page, Heidelb., 1596), Gr. et Lat., by Bersmann, in which the Greek text was altered in a very arbitrary manner by Camerarius, who had persuaded himself that the numerous false quantities that he found in the verses were merely the mistakes of the transcribers. I. Corn. de Pauw's edition, Traj ad Rhen., 1730, 4to., Gr. et Lat., is augmented by some fragments taken from a MS. in the Bodleian Library at Oxford, which Fabricius had before inserted in his 'Biblioth. Græca:' it is not very highly esteemed, and was severely criticised by D'Orville, in the sixth volume of Burmann's 'Observationes Miscellaneæ.'

An edition of the other poems of Philes (some of which had been inserted by Fabricius in his 'Bibl. Gr.') was published, Lips. 1768, 8vo., Gr. et Lat., by Wernsdorf, with notes and an excellent preliminary dissertation on the Life and Works of Philes. The longest poem in the volume is one of nearly a thousand lines written in the same barbarous kind of verse, in the form of a dialogue between the author and the city of Constantinople, which he designates by the name Νοῦς, *mens*. It is composed in praise of Joannes Cantacuzenus, who was afterwards emperor, and in it is introduced a personification of his several virtues, Prudence, Fortitude, Justice, Temperance, Truth, Memory, Pity, Clemency, Sagacity, Rectitude, Continence, and Modesty. The other poems consist of epigrams and various shorter pieces, together with one of nearly four hundred verses on the Elephant, addressed to an emperor named Leo, which (as no emperor of that name was contemporary with Philes) probably belongs to some other person. (*Miscell. Observ. in Auctor. Vet. et Rec.*, vol. ii., tom. iii., p. 425.) Two other short poems, in the same metre as the rest, are to be found in the first volume of Cramer's 'Anecdota Græca Parisiensia,' p. 43, Oxon., 8vo. 1839. Wernsdorf gives, in his 'Preliminary Dissertation,' a list of several works by Philes which still remain unedited in various libraries of Europe. (Fabr., *Bibl. Gr.* and *Biogr. Univers.*, as the writer has not been able to consult Wernsdorf's 'Dissertation.')

PHILE'TAS, a grammarian and poet of the island Cos, flourished in the times of Philip and Alexander the Great, and was preceptor to Ptolemy Philadelphus. He wrote epigrams, elegies, and other poems, and died of emaciation brought on by excessive study. (Suidas, *Lexicon*.) Fragments of Philetas and two other poets were edited by Bachius, 8vo., Halle, 1829.

PHILIDOR, ANDRE', a French dramatic composer of eminence in his day, but better known out of his own country as a most distinguished and unrivalled chess-player, was born at Dreux in 1726. His grandfather was musician in ordinary to Louis XIII.: his father held the same office, and his uncle established, in 1726, the famous *Concert Spirituel*. André was admitted at the usual early age as a page, or chorister, in the chapel of Louis XV., and studied under Campra, *Maître de la Chapelle*. In 1737, when he had only completed his eleventh year, he produced a motet for a full choir, for which the *Grand Monarque* deigned to thank him; but it does not appear that this condescension was followed by any acknowledgment of a more solid kind, for after quitting the chapel on his voice changing, he subsisted for some time by copying music—a drudgery to which Rousseau was obliged to submit—and in giving a few lessons. But all his vacant hours, and these were many, he devoted to the game of chess, in which his proficiency was so great, that he sought to profit by his skill, and in 1745 commenced a tour in Holland, Germany, and England. This also enabled him to improve his knowledge and taste in music, by hearing the best works of the great masters. He tried his strength as a composer in London in 1753, by setting Congreve's Ode to Harmony, which Handel heard, who approved his choruses, but thought him defective in melody. Chess however had occupied more of his thoughts than his avowed profession, and he had previously, in 1749, published his *Analysis of the Game of Chess*, for which he obtained a great list of subscribers, and his reputation was established. This work gives several games, with notes explaining the reasons for the moves; and thus it is the most useful of all books for those who study chess.

In 1754 he returned to Paris, and devoted himself wholly to his profession. He composed some sacred music, which the king thought too much in the Italian style, and thus his effort to obtain the appointment of *Maître de la Chapelle* was frustrated. Four years after this he turned his attention to dramatic music, and produced at the *Opéra-Comique* many works, most of which proved eminently successful, insomuch that M. de Laborde, in his voluminous *Essai sur la Musique*—a work to which we are indebted for most of the foregoing—does not hesitate to pronounce him one of the greatest of French composers. The author of the *Dic-*

tionnaire des Musiciens considers him to have been, together with Duni and Monsigny, the joint father of the *Opéra Comique*, but adds that, though he was a profound harmonist, he was not so happy in melody.

In 1777 Philidor reprinted his treatise on chess, considerably augmented. In 1779 he produced at Free-Masons' Hall, in London, the *Carmen Seculare* of Horace, set to music, consisting of airs, choruses, &c., which it was rumoured he had written in imitation of the antient music, though such had never been his intention, and some disappointment was excited in many who expected a revival of those miraculous effects, in which a few were still credulous enough to believe. This was published in 1788, in a splendid volume in score, dedicated to Catherine of Russia; and as the work is now before us, we are enabled to corroborate what Dr. Burney has said of it;—that the choruses are after the model of Handel, and the airs after those of his own and Gretry's comic operas, many of which, 'particularly Gretry's, would be elegant and pleasing music anywhere.' It was again performed, under the composer's direction, in 1788, at an entertainment of a mixed kind given by the Knights of the Bath at the Pantheon. From that period Philidor seems to have passed much of his time in London, chiefly occupied by the game of chess, at which he played at Parsloe's (now the Albion Club) in St. James's Street, where, we believe, persons were admitted to witness his exploits, on the payment of a small fee. It was there he exhibited his marvellous powers, by playing three games, against different adversaries at different boards, all at the same time. And only two months before his decease he played two games, blindfolded, simultaneously, against very expert players, and was victorious.

His health now rapidly declining, he applied for a passport to return to his native country, but was refused, having been, most unjustly, proscribed by the French government as a suspected person. This affected him deeply; his grief admitted of no alleviation, and he died in London, in 1795.

Philidor was a very worthy and amiable man; but it was the generally-received opinion that his mental powers were almost exclusively confined to music and chess.

PHILI'NUS (Φιλῖνος), a Greek physician, born in the island of Cos, was one of the pupils of Herophilus, and (according to Galen, *Introduct.*), the founder of the sect of the Empirici. [EMPIRICI; SERAPION.] He lived somewhere about the year B.C. 250 (Ol. 132, 3), wrote a work on botany (Athen., *Deipnos.*, lib. xv., sec. 28, pp. 681, 682), which is probably the work quoted by Pliny (*Hist. Nat.*, lib. xx., cap. 91), and some commentaries on the aphorisms of Hippocrates (Erotian, *Lex. Voc. Hippocr.* in ἄμβην), neither of which works is now extant. With respect to the system of the Empirici, the rejection of anatomy, physiology, and pathology as useless studies, would of course, at least in the opinion of modern physicians, prevent their ever attaining any higher rank than that of clever experimentalists; but still it must not be denied that Materia Medica is indebted to them for the discovery of the properties of many valuable drugs. A parallel has been drawn between the antient Empirici and the modern Homœopathists, by Fred. Ferd. Brisken, entitled 'Philinus et Hahnemannus, seu Veteris Sectæ Empiricæ cum Hodiernâ Sectâ Homœopathicâ Comparatio,' 8vo., Berol., 1834, pp. 36.

PHILIP, the name of several kings of Macedonia, of whom two deserve particular notice. [MACEDONIA.]

PHILIP, a younger son of Amyntas, succeeded (B.C. 359) at the age of twenty-three years to a throne which, since the death of his father, and during the reigns of his two elder brothers, Alexander and Perdiccas, had been shaken to its foundation by foreign invasion and civil war. Fortunately for the independence of his kingdom, the young monarch was endowed with talents and energies of the highest order; and a residence during his boyhood at Thebes, whither he had been sent as a hostage in the best days of the republic, while the celebrated Pelopidas and Epaminondas were in power, had obtained for him all the advantages of a liberal Grecian education. On his accession to the throne, his inheritance was overrun by the victorious Illyrians, who had defeated and slain his brother Perdiccas; his own title was disputed by two pretenders to the crown; and the people of Macedonia were dispirited by accumulated national calamities. But his courage and eloquence revived the hopes of his subjects; and his military skill and activity soon inspired them with confidence. While these qualities were successfully exerted in the field, negotiations and bribes were as artfully employed to induce the supporters of the rival claimants to abandon their cause; and Philip finally not only repelled the Illyrian and Pæonian invaders of his country, but penetrated in turn into their territory, and extended his own dominions at their expense. He subsequently further strengthened himself by a marriage with Olympias, daughter of the king of Epirus, who became the mother of Alexander the Great, but whose temper and conduct made her so little agreeable to her husband, that he finally divorced her.

From the period of the full establishment of his authority over his native kingdom, Philip seems to have commenced the design, which he thenceforth steadily pursued and ultimately accomplished, of destroying the power and influence of the Athenian people on the northern shores of the Ægean Sea. As his projects, both on the present occasion and subsequently, brought him into frequent collision with that republic, the state of affairs at Athens throughout his reign requires some detailed notice.

After the general peace which followed the battle of Mantineia and death of Epaminondas (B.C. 362), Athens had again become the most prominent state in Greece. The naval successes and moderation of Timotheus and a a few other officers of similar character had won her the public respect; and the people of the Ægean islands and coasts, to secure the protection of her navy against piracy, had resumed their relations to her as subject allies. She had thus nearly recovered the naval supremacy lost by the fatal termination of the Peloponnesian War: but this brief renovation of glory was soon obscured by a relapse into former habits of oppression towards her allies; and these produced (B.C. 358) the Confederate or Social War, by a league of some of the dependent islands and towns against her, which lasted three years, and ended in the loss of her sovereignty. Philip ably took advantage of the distraction of Athens in this contest to reduce or win over in succession Amphipolis, Pydna, Potidæa, and other towns on the northern shores of the Ægean, until in those parts Methone alone remained in the Athenian interest. Some conquests in Thrace also gave the Macedonian prince possession of the gold-mines of Pangæus; and near these he built or enlarged a city, which he peopled with Greeks from the conquered towns, and named after himself Philippi. Here, under his personal inspection, the mines were worked to such advantage, that they produced him one thousand talents annually; and the gold 'Philips' which he coined served him in the sequel both to bribe the venal orators of the Grecian states and to hire the mercenary troops with which he now openly assailed their freedom.

The ambition of Philip indeed soon taught him to extend his views of aggrandisement into Greece itself; and, at whatever epoch the plans were organised which he formed and realised for the acquisition of a general supremacy over the Grecian states, the first occasion for interfering in their domestic politics was afforded to him by the Phocian or Sacred War, which had already commenced before the close of the contest between Athens and her allies. The real cause of the persecution of the Phocians was the hatred with which that people had inspired the Thebans by refusing to join them in the late war against Sparta. To this source of political enmity were added some uncertain motives of personal offence between individuals of the neighbouring communities; and, moved by such passions of public and private revenge, the Thebans rashly excited a commotion which was doomed eventually to bring destruction upon their own state, as well as to annihilate the general liberties of Greece. Availing themselves of their influence in the Amphictyonic Council, of which they hoped also to obtain the absolute control, as well as the command of the temple of Delphi and its treasures, by destroying the Phocians, they accused that people of having cultivated lands which had been devoted to the Delphic god. The Phocians were found guilty by the compliant Amphictyons, and condemned to pay a fine so enormous, that for its liquidation their whole country was declared forfeit to the god. Perceiving that their only appeal against this iniquitous sentence must be to arms, the Phocians anticipated their enemies by boldly seizing upon Delphi (B.C. 357), and, supported by Athens and Sparta, they commenced a sanguinary war with the Thebans and their allies.

During the progress of this struggle, Philip gained a footing in Thessaly by assisting some of the Thessalian nobles, or the Aleuadæ, the antient allies of Macedon, against the tyrants of Pheræ, who were supported by the Phocians and their Athenian confederates. The successful interference of Philip in this quarter brought him into opposition with Athens; but the jealousy of that republic was still more excited by his continued machinations against her influence on the Thracian coasts. When she attempted, in conjunction with the people of Methone, to repel these injuries by hostilities, he suddenly appeared before that place, and took it, after an obstinate siege, in which he lost his left eye by an arrow. The people of Olynthus, hitherto his allies, now taking alarm at his ambition, applied to Athens for aid against him; but though the Athenians, moved by the eloquence of Demosthenes, repeatedly sent reinforcements to the Olynthians, Philip defeated the confederates, and finally besieged and captured Olynthus (B.C. 347). After this event, both the Athenians and the Macedonian prince were equally desirous of peace, and in the following year a treaty was concluded between them. But the ambassadors who were sent to Philip to arrange the terms suffered themselves to be either outwitted or bribed by the artful monarch; and the Phocian allies of Athens were excluded from the benefits of the treaty.

That brave and unfortunate people, who had hitherto maintained the war with advantage, were now abandoned to the mercy of their more numerous and powerful enemies. The Thebans, who were nearly exhausted in the struggle, applied to Philip for aid, which he was but too happy to render. From Thessaly, passing the defiles of Thermopylæ, which had been left unguarded, he marched rapidly into Proper Greece; and, profiting by the misconduct of party leaders and the treachery of the Phocian general, he was completely successful. The Phocians were compelled to surrender unconditionally; the Amphictyons assembled, and decreed that their towns should be destroyed and the inhabitants disarmed and heavily assessed; and their privileges at Delphi and votes in the Amphictyonic Council were solemnly transferred to the pious monarch of Macedon. Thus ended (B.C. 346) the Sacred War, which ruined an innocent people and destroyed the little reverence for religion that had yet remained in Greece.

The crisis was now approaching in the great struggle between Athens and Philip, which, on the part of the former, was for the independence of Greece, and on that of the latter, for the general supremacy in her national government and councils. But the contest was almost as much one of factions at Athens itself, as between the republic and the Macedonian king. The aristocratic party in that city inclined, perhaps naturally, to the side of Philip, through conviction of the degenerate character of the democracy and consequent hopelessness of a successful collision with the power of Macedon, which they either thought it useless to resist, or considered not likely to be injurious to their country. They might also sincerely believe that in Greece, for all the evils of intestine commotions of which they were weary, there remained no cure but a general diversion, headed by Macedon, of the national energies against Persia. Their leaders were the venerable Isocrates and upright Phocion, both patriots of unquestionable integrity, and anxious for the independence of Athens. But it was the misfortune of this party, that its ranks gave shelter to the venal orators, such as Æschines, Demades, and others, who were undoubtedly in the pay of Philip, and who basely promoted his designs. On the other hand the democratic, or war party, as a modern historian has termed it, ever eager for the licence and plunder which were promised by a state of hostilities, was principally guided by the infamous Chares, to whom, together with the mercenary Charidemus, the conduct of military expeditions was often entrusted. But to this party, through a well-founded persuasion of the ambitious project of Philip, and a generous and patriotic enthusiasm for the independence of his country, had the great Demosthenes attached himself, and a view of the principles upon which he acted will be found in a former article. [DEMOSTHENES.]

After the conclusion of the Phocian war, Philip turned his attention for a time again to the northward of Greece, and laboured to consolidate his empire in that quarter by obtaining possession of the cities of the Propontis and Thracian Chersonese. But Demosthenes had now roused the Athenians to so much alarm and energy, that when the Macedonian attacked and invested Perinthus and Byzantium, a strong armament was fitted out at Athens, which, under the command of Phocion, compelled him to raise the siege of those cities (B.C. 339). This was perhaps the most glorious moment in the life of Demosthenes, and the most mortifying check in the successful career of Philip. But the triumph of the great orator and the disappointment of the ambitious prince were alike only momentary; and the event soon proved how unequal was the conflict between the desultory impulse which could be given to a fickle and divided democracy, without secrecy, unity, or consistency of purpose, and the concentrated power of a monarch of high talent and immense resources, whose politic designs were veiled in the profoundest mystery until they were ripe for execution by adroit ministers, experienced generals, and well-disciplined armies. In the very next year after his repulse before Byzantium, Philip found a pretext for appearing again in arms in Greece itself. He was appointed by the obsequious Amphictyonic council their general in a new sacred war which they had denounced against the people of Amphissa for cultivating some devoted lands; and after reducing that city, he suddenly threw off the mask by seizing Elateia, the key of Bœotia, at the head of 32,000 veteran troops. The Athenians were filled with dismay; but the eloquence and activity of Demosthenes both animated them to signal exertions, and induced the Thebans, Corinthians, and others to join with Athens in the cause of independence. The numerical superiority of the confederates however, though they fought with great bravery, could not prevail against generalship and discipline; and the fatal battle of Chæroneia (B.C. 338) for ever extinguished the liberties of antient Greece.

Nothing was more characteristic of the disposition and policy of Philip than his conduct after the battle of Chæroneia. As soon as the victory was secured, he immediately, with his usual humanity, stopped the slaughter; and when, on revisiting the field next morning, after a night of carousal, he beheld the dead Thebans of the Sacred Band lying in ranks where they had valiantly fought and fallen, he is said to have shed tears, and exclaimed, 'Perish they who imagine these to have done or suffered shame!" But this burst of admiration did not prevent him from treating the party that had been hostile to him at Thebes with great severity; and he imposed a Macedonian garrison upon the subjugated city. To the Athenians, on the contrary, he behaved with the greatest clemency, dismissing without ransom those among them who had been made prisoners, and granting their republic peace upon very easy terms, the principal condition being that they should send deputies to a general congress of the Amphictyonic states at Corinth. Here the great object of the ambition of Philip seemed to approach its fulfilment. After his orators had set forth the injuries which Persia had continually inflicted upon Greece, it was unanimously resolved in the assembly that a national war should be declared against the Persian empire, and that the Macedonian king should be appointed commander-in-chief, with power to apportion the contingent of each Grecian state. But when he was making the most active preparations for the great expedition which he meditated, and which his son was destined to accomplish, his days were cut short by the hand of an assassin. While celebrating the nuptials of his daughter Cleopatra with the king of Epirus, he was stabbed by a young Macedonian of his own body-guard, Pausanias, whose motive for the deed, as he was himself put to death on the spot, could not be ascertained, but has been most probably ascribed to personal revenge, on the king's refusal to grant him redress for an intolerable insult which he had received from the queen's uncle.

Thus fell Philip (B.C. 336), at the early age of forty-seven years, and in the full vigour of life and intellect, at the moment when he seemed to be entering on the meridian splendour of his career of glory.

The character of Philip of Macedon has often been sketched, like too many other historical portraits, in the spirit of party. A distinguished historian of our own times has depicted all his actions in the most favourable colours, apparently with no better object than to blacken the general cause of democracy in the conduct of his Athenian opponents. On the other hand, the ardent advocates of republican freedom have not unnaturally been led to regard the Macedonian king with strong prejudice as the exemplar of monarchical tyranny. Of all the princes of antiquity however, it would be difficult to name one worthy of comparison with Philip in the fairer features of his character. His government of his own kingdom must be judged, by the silence of his opponents, to have been mild, just, and popular. Personally kind to his enemies, he was to a singular degree free from that cruelty which was the common reproach of the Greeks of his age: humane, generous, and magnanimous, he often showed himself capable of forgiving injuries, of sparing the vanquished, and of using success with moderation. It was indeed his boast and his truest glory, that he conquered more by mercy and conciliation after victory than by mere force of arms. His splendid abilities were equally conspicuous as a statesman and a general; and his intellectual tastes for literature and philosophy, for the drama and the arts, were alike refined and passionate. He made his court, therefore, no less the seat of eloquence and mental cultivation than it was the school of consummate political science. That he was as insatiable in his ambitious schemes as he was unscrupulous in the means which he employed to advance them, is true: he hesitated as little as most politicians at corruption and perfidy. But his ambition was not of a vulgar cast; nor while the conquest of the vast Persian empire was its magnificent project, does he at all seem to have aimed at the internal subjugation of the Grecian states, or to have desired more than the supreme authority to lead their free and enlightened confederation against the barbarism of the East. The vicious intemperance of his private life will not bear any comment; but his vices, like his accomplishments, were those of the Greeks, and of the state of society which produced them: his virtues were peculiar to himself, and superior to his times.

Coin of Philip II.
British Museum. Actual size.

PHILIP, the only other of the Macedonian kings of that name whose life and reign merit some attention, ascended the throne (B C. 220) at an early age, on the death of his uncle Antigonus Doson. He was the grandson of Antigonus Gonnatas, and therefore lineally descended from the first Antigonus, one of the generals of Alexander the Great, whose family, in the vicissitudes which succeeded the dismemberment of that conqueror's empire, had finally obtained the crown of Macedon and a general ascendency over the affairs of Greece. Philip was an able prince, whose character, both in its political energies and personal vices, was not without some points of resemblance to that of his greater namesake and predecessor on the Macedonian throne. At the commencement of his reign, the struggle between the Ætolian and Achæan leagues, in which the latter people had been worsted, caused them to call in his aid; and in the war which followed, and in which he was placed at the head of the Achæan confederation, his activity and military skill were much distinguished. His successes soon disposed the Ætolians to peace, which he as readily granted them, in order that he might direct his sole attention to Italy, where the disasters of the Romans in the second Punic War inspired him with the hope that, by throwing his weight into the Carthaginian scale, he might finally acquire the preponderance of power for himself. With this view, after the battle of Cannæ (B.C. 216), he formed with Hannibal an alliance offensive and defensive, which he prosecuted with little vigour, but which ultimately proved his own ruin; for the Romans, after the great crisis of their fate was over in Italy, no sooner began to prevail in the struggle with Hannibal, than they determined to take vengeance upon Philip for his aggression. After some intervals of indecisive hostility and hollow pacification, during which they found means to deprive him of most of his allies in Greece, they declared war anew against him on various pretexts; and at length he sustained from the consul T. Quinctius Flamininus, at Cynoscephalæ, in Thessaly (B.C. 197), a defeat so decisive, as for ever to break the Macedonian power. Philip however, after this calamity, obtained peace on terms less severe than might have been anticipated: but his proud and restless spirit could ill brook the subjection to which he was reduced; and the remaining years of his life were passed in covert preparations for a new war with Rome, which he saw to be inevitable. He died (B.C. 179) just before the last crisis in the fortunes of Macedon, leaving his unworthy son Perseus to abide the struggle which was to bereave him of his crown and liberty.

The original materials for the life and reign of the first of these two Philips are scattered through the extant orations of Æschines and Demosthenes, the compilation of Diodorus Siculus, and the Lives of Demosthenes and Phocion by Plutarch. Among our modern historians, Mitford has given an elaborate though far too favourable view of his actions and character. The original authorities for the reign of the last Philip are Polybius and Livy.

PHILIP, ST., was the first disciple of Jesus Christ, and one of the twelve apostles. He was a native of Bethsaida, a town near the sea of Tiberias. After his call to the apostleship not much is recorded of him in the New Testament. He has sometimes been confounded with Philip the Deacon, mentioned in the Acts of the Apostles; but a little examination will plainly show that they were quite different persons.

Nicephorus Callisti tells us that in the distribution of regions made by the Apostles for their respective spheres of labour, St. Philip had Syria and Upper Asia assigned to him, with St. Bartholomew; and that having there made numerous converts, he came into Hierapolis in Phrygia, where he succeeded in bringing many of the inhabitants from gross idolatry to the belief and practice of Christianity, on which account he was at length seized by the authorities, imprisoned, and scourged, and then martyred by being hanged upon a pillar, but in what year is not stated.

The Gnostics attributed a book to St. Philip, which they called his Gospel; but no other sect ever pretended that this apostle left any writings.

The feast of St. Philip is observed by the Eastern churches November 14th, but by the Western on the 1st of May

(Isidore of Pelusium; Nicephorus Callisti; Cave, *Lives of the Apostles*.)

PHILIP OF THESSALONI'CA. [ANTHOLOGY.]

PHILIP was the name of five Spanish sovereigns, four of whom were of the house of Austria, and one of the Bourbon family.

PHILIP I., king of Castile, surnamed the Handsome, was the son of Maximilian I., emperor of Germany, by Mary of Burgundy, in right of whom he inherited and transmitted to his posterity of the house of Austria, the seventeen provinces of the Netherlands. In the year 1496 he married Joanna, or Jane, eldest daughter of Ferdinand the Catholic and Isabella, sovereigns of Aragon and Castile; and in 1504, on the death of Isabella, who bequeathed the kingdom of Castile to her daughter Jane, Philip, as well as his consort, assumed the regal title. He was crowned at Burgos with her; and in consequence of her mental weakness, exercised all the functions of government during the short remainder of his life, which closed in the following year, at the early age of twenty-eight.

His queen Jane survived him for fifty years, in a state between insanity and fatuity; and her malady is said to have been much aggravated by grief at his death, though he had never loved her. She traversed her kingdom, carrying his dead body with her, and causing it to be uncovered at times that she might behold it; until she was at last persuaded to permit its removal and interment. She had by Philip, besides daughters, two sons, both in the sequel emperors of Germany, as Charles V. and Ferdinand I., the elder of whom, Charles, on the death of his grandfather Ferdinand the Catholic, finally re-united the crowns of Castile and Aragon. But such was the attachment of the nation to their insane queen, that throughout her long life she was always recognised as sovereign of Spain in conjunction with her son; and their names were mentioned together in every formal act of government.

PHILIP II., king of Spain, the only legitimate son of the emperor Charles V. by Isabella of Portugal, was born in the year 1527, and ascended the Spanish throne on his father's abdication in 1556; having in the preceding year entered on the government of the Netherlands, which Charles had in the same manner resigned to him. His inheritance also included the kingdom of the Two Sicilies, Milan with other Italian provinces, and the empire of the New World; and it was a true and expressive phrase for the extent of his power, that 'the sun never set upon his dominions.' The revenues which he drew from the American mines and his European realms far exceeded those of any prince of his times, and are declared to have amounted to twenty-five millions of ducats yearly. His navy was more numerous than that of any other power; and his veteran armies were composed of the best troops, led by the ablest generals of the age.

As the reign of Philip II., which fills a long and important period in European history, received its dark colouring from his personal qualities, a slight preliminary sketch of his private character will best illustrate the features of his policy and the events which it produced. He was naturally of a stern and morose temperament; and the austerities of a monastic education, aggravating this constitutional defect, had extinguished in his soul every joyous emotion. As he had also been deeply imbued from his youth with religious doctrines, the very sincerity of his belief acting upon a cold heart, a gloomy temper, and a narrow mind, was sufficient to render him obstinately bigoted and inexorably cruel. In temporal affairs, the despotic principles in which he had been brought up had filled him with extravagant ideas of regal authority; and his father's example had taught him to aspire to universal monarchy. With a superstitious creed he therefore mingled the most unbounded schemes of worldly ambition; and perhaps conscientiously believing that with his own projects of dominion he was promoting at the same time the glory of God, he pursued without remorse the most inhuman course of religious persecution and civil tyranny.

Philip has therefore truly been represented as a monster of bigotry and cruelty; but it appears unjust to add to these revolting qualities, as some writers have done, the reproach of hypocrisy. Schiller, who has deeply studied his character with philosophic scrutiny, and whose feelings are anything but favourable to him, yet concludes, with more candour and acuteness (*Abfall der Niederlande*), that he was a better man than his father: since Charles V. was a persecutor only from policy, but Philip from conviction. Charles made religion subservient to his views of temporal aggrandisement; Philip often sacrificed his true political interests to what he conceived to be the service of religion. The emperor held the pope a prisoner, while he burnt others for denying his supremacy: his son engaged only with deep reluctance in a legitimate war against pope Paul IV.; and in order to purchase a reconciliation with that arrogant pontiff, he abandoned the fruit of victory like a repentant criminal. The indulgence of sensual passion has been adduced as another proof, no less than his cruelty, of the hypocrisy of Philip's religious pretensions: but the occasional licence of his private life in this respect was one of those inconsistencies which have sullied purer minds. There seems indeed no reason to doubt the sincerity of Philip's faith; it is more rational and useful to observe the fatal perversion of principle, by which the infliction of torture and death is imagined to be an exercise of virtue, a religious duty, and an acceptable offering to the God of mercy.

The marriage of Philip II. with Mary, queen of England, which had taken place in 1554, enabled him, soon after his accession to the Spanish crown, to engage his consort's kingdom with his own, in 1557, in a war against France. The only memorable event of this contest was the victory of St. Quentin, gained by his troops. He was not himself present at the battle: but at the subsequent assault of the town he showed himself in armour to encourage the soldiery, though without sharing their danger; and it was observed that this was the first and last time in which he wore a military dress or appeared on the field. The war was concluded in 1559, by the peace of Cateau Cambresis, upon terms advantageous for Philip. He had meanwhile, by the death of Mary, to whom he had been a cold and unkind husband, lost his connection with England. Leaving his provinces of the Netherlands under the government of his natural sister Margaret, duchess of Parma, Philip sailed for Spain, which he never quitted again; and his arrival in that kingdom was immediately followed by a sanguinary persecution, through which he succeeded in crushing the germs of the Reformation in the peninsula. He was present at an *auto-da-fe*, or public act of faith, at which forty unhappy persons were led to the stake by the Inquisition. When passing him, one of the victims in this dreadful procession appealed to him with loud cries of mercy: 'Perish thou and all like thee!' was his merciless reply. 'If my own son were a heretic, I would deliver him to the flames.'

It was amidst such scenes that he accomplished a vow made to heaven and to St. Lawrence, on the day of which saint the battle of St. Quentin had been gained, to testify his gratitude for that victory. At the village of Escurial, near Madrid, he built a superb palace, to which, in honour of the saint and of the instrument of his martyrdom, he gave the form of a gridiron. At the same period he transferred the seat of government from Toledo, the antient capital of Castile, to Madrid, which latter city thenceforth became the metropolis of Spain. In the south of that kingdom, his persecution goaded to revolt the Moorish population, who had compounded for the quiet possession of their native seats by a pretended conversion to Christianity; and after a furious contest, embittered by religious hatred and marked by horrid atrocities on both sides, a portion of the Moors were driven to seek refuge in Africa, and the remainder (A.D. 1571) reduced to submission.

Meanwhile Philip diligently applied himself to the extirpation of heresy in the rest of his dominions. In his Italian possessions, both of Milan and Naples, fire and the sword were successfully employed for this purpose; but the attempt to establish the Spanish Inquisition in the Netherlands with the same view, first provoked a spirit of insurrection (A.D. 1566), which, throughout the remainder of his long reign, exhausted his immense resources of men and money, and after the frightful devastation of those fertile and flourishing provinces, for ever tore seven of them from the Spanish monarchy. When Philip found that the government of Margaret of Parma wanted strength to enforce his religious edicts in the Netherlands, he replaced her by the ferocious Ferdinand Alvarez de Toledo, duke of Alva. The character of this man's administration may be estimated by his sanguinary boast, that in less than six years he had consigned 18,000 heretics to the stake and the scaffold, before his master was compelled, by the failure of his cruel measures, to recal him. The milder government of his successor Requesens; the warlike renown, the energies, and the artifice of Don John of Austria, natural brother of Philip (who had gained for him the great naval victory of Lepanto over the Turks in 1571); and the military genius of Alessandro Farnese, duke of Parma, the ablest general of his times;—were all in succession equally ineffectual to suppress the revolt of the Netherlands. William the Silent, prince of Orange, whose deep enmity Philip had provoked, proved the most dangerous of his insurgent subjects; and under that prince and his son Maurice, they successfully prosecuted a struggle, of which the principal events are related under another head. [NASSAU, HOUSE OF.]

While the bigoted tyranny of Philip was thus dissevering seven provinces of the Netherlands from his dominions, he unexpectedly acquired possession of another kingdom. On the death of Henry, king of Portugal, without issue, Philip as his nephew asserted his title to the succession; and his power easily enabling him to prevail against his feeble competitor, Don Antonio de Crato, his troops, under the Duke of Alva, entered Lisbon, and in two months (A.D. 1580) annexed the Portuguese crown and colonial dependencies for sixty years to the Spanish monarchy.

This acquisition seemed but a step to the universal dominion at which Philip aimed; and in the pursuit of his double ambition of extending his sway and extirpating the Protestant faith, the remainder of his life was passed in designs for subjugating both France and England. In the former country, after secretly allying himself with the queen mother, Catherine de' Medici, and the Romish party, for the destruction of the Huguenots, he subsequently and openly supported the Catholic league, under the Guises, against Henri IV.; and it was not until that sovereign, by changing his religion, completed his victories over the league, that the subtle tyrant of Spain abandoned his hopes of reducing France to subjection. His project for the conquest of England was more avowedly proclaimed, and more disgracefully defeated. But it is needless in this place to repeat the narrative, so glorious in our annals, of the destruction of the magnificent fleet of one hundred and fifty vessels of war, which, under the presumptuous title of the Invincible Armada, Philip had equipped for the reduction of this island (A.D. 1588). The manner in which he received the mortifying intelligence of the annihilation of his fondest hopes by the shipwreck as well as the defeat of his navy, displayed some greatness of mind as well as religious resignation: 'I sent my fleet,' said he, 'to combat with the English, but not with the elements: God's will be done!'

The close of Philip's reign and life must have been embittered by the failure of all his plans of ambition and intolerance. The contest in the Low Countries was daily becoming so adverse to the Spanish arms, that one of his last acts was an abdication of his title over the whole of those provinces in favour of his daughter Isabella and her consort the

Archduke Albert. His haughty spirit was reduced to submit to this measure, as the only remaining expedient for preventing the total alienation of the Netherlands from his house. England and France also had escaped from his toils; and the peace of Vervins, which he was compelled to conclude with Henri IV., left that sovereign securely established on the French throne. Philip died in the same year (A.D. 1598), at the age of seventy-two, after protracted and excruciating suffering, under a complication of dreadful maladies, which he bore with exemplary fortitude and resignation.

Philip II. was four times married. The queen of England, by whom he had no issue, was his second wife. His first was his cousin, Mary of Portugal; and by her he had one son, Don Carlos, whose fate has deepened the sombre aspect of his reign. That young prince, who appears to have been of a haughty and violent temper, was exasperated by his father's refusal to admit him to a share in the administration of the kingdom, though he had never shown any capacity for public affairs. After giving many proofs of a discontented and disordered mind, he was, on an accusation of holding a treasonable correspondence with the Flemish insurgents, arrested in his bed by Philip himself, at midnight on the 18th of January, 1568, and committed to a prison, where in a few months he terminated his miserable existence, at the age of twenty-three years, and not without the horrid suspicion that his death had been hastened, through poison or other means, by his father's command. But the authentic version, which we have related, of this mysterious and tragical affair has been variously discoloured by calumny and fiction. Writers, who believed or feigned Philip capable of any atrocity, have asserted without sufficient evidence that he was the murderer of his son; and upon this foundation has the superstructure been formed for a romantic tale of a mutual and criminal passion between Don Carlos and his father's third wife, the Princess Elizabeth of France, who had originally been betrothed to himself, and whose life, which closed quickly afterwards, is also said to have been sacrificed to the jealous vengeance of her husband. For this charge against all the parties, there seems however to have been no foundation. By Elizabeth, Philip had two daughters, who, together with his son and successor by his fourth wife Anne, daughter of the emperor Maximilian II., were the only legitimate issue which he left. In the midst of his persecuting zeal, he had given one purer proof of his regard for religion; and sacred literature owes an obligation to his memory for the publication of the beautiful Polyglot Bible which bears his name, and which was printed at Antwerp in 1569-72, in 8 volumes, folio.

PHILIP III. was a prince, in everything except the bigotry of his faith, of a character most opposite to that of his father. Gentle, humane, and unconquerably indolent, he surrendered himself and the whole management of his affairs, from the very commencement of his reign, to the guidance of his favourite, the marquis of Denia, who had been his chief equerry, and whom he raised to the dignity of duke of Lerma. This nobleman, who governed Spain as prime minister with unbounded power for twenty years, was a personage of dignified mien and of a mild and beneficent disposition; but as a statesman, though he wanted neither prudence nor firmness of spirit, he was otherwise of only moderate capacity, and he rendered his administration injurious to the state by his love of pomp and lavish expenditure, and the consequent derangement of the national finances. He was supplanted at last in the affections of his feeble master (A.D. 1618) by his own ungrateful son, the duke of Uzeda, under whom the kingdom was not better governed; and the aged Lerma was solaced by the pope in his unmerited disgrace with a cardinal's hat, which he had used the foresight to solicit a little before his fall, as a protection from the persecution of his enemies.

The principal circumstances which distinguished the reign of Philip III. were the recognition of the independence of the revolted provinces in the Low Countries, and the expulsion of the Moors from Spain. Notwithstanding the cession by Philip II. of the general sovereignty of all the Netherlands to his daughter Isabella and her husband the archduke Albert, which was ratified by Philip III. immediately after he ascended the throne, the war in those provinces continued with unabated fury, and with indifferent success to the Spanish arms, until the year 1609; when the exhaustion of the immense revenues of the monarchy compelled the duke of Lerma to conclude in his master's name a truce for twelve years with the Seven United Provinces, by which the king of Spain acknowledged them for free and independent states. In the same year, under the plea that the remains of the Moorish population in Spain, notwithstanding their pretended conversion to Christianity, continued in their hearts to be obstinate infidels, and to hold treasonable correspondence with their African brethren, a royal edict was issued, commanding all the Moors in the kingdom of Valencia to quit the Spanish dominions; and soon after a decree, extending this sentence of banishment to all the Moors in the peninsula, completed (A.D. 1610) the fatal measure, from which Spain has never recovered. On the impulse of a blind superstition, and contrary to every dictate of wise policy, above a million of the most industrious subjects of the Spanish crown were driven into exile; and the most flourishing provinces were depopulated by their removal to the opposite shores of Barbary. [MORISCOES.]

After these events Spain may be said to have languished, rather than found refreshment, in peace, which was interrupted but slightly, by the commotions of the times in Italy and Germany, during the remainder of the reign of Philip. That prince terminated his existence by a fever in the year 1621, at the age of forty-three years. By his queen, Margaret of Austria, he left three sons: Philip, who succeeded him; Charles, who died in 1632; and Ferdinand, for whom, at the age of only ten years, he obtained from the pope a cardinal's hat, with a dispensation to hold by proxy the archbishopric of Toledo, and who, in consequence of these ecclesiastical dignities, is known in history under the title of the cardinal-infant. Of his daughters, the eldest, Anne, married Louis XIII. of France; and the second, Maria Anne, after having been contracted to Charles I. of England, when prince of Wales, was finally married to the king of Hungary, who subsequently ascended the Imperial throne under the title of Ferdinand III.

PHILIP IV. was only sixteen years of age when he ascended the throne; and, like his father, after he had become the sovereign of his people, he remained the subject of a favourite. This was the famous count-duke Olivarez, by which peculiar title he chose to be styled, a man of self-sufficient confidence and inordinate ambition, who affecting to condemn the supine inactivity of the last reign, and to pursue a more vigorous course of policy, concluded for his sovereign with the emperor a strict family league for the aggrandisement of both branches of the House of Austria. The means proposed for this object were the renewal of the war in the Low Countries at the expiration of the twelve years' truce, and the consolidation of the Spanish power both in these provinces and in Italy; while in Germany the Imperial authority should be secured by the subjugation of the Protestants. It was hoped that France, torn by religious wars, could offer no resistance to these designs; and England was to be amused with that matrimonial treaty which produced the strange journey of Prince Charles, attended by the duke of Buckingham, to woo the infanta Maria Anne at Madrid.

These intrigues were among the preludes to the long and sanguinary wars which were only terminated in Germany by the peace of Westphalia, and which continued between Spain and France above ten years later, until the treaty of the Pyrenees. In the Netherlands, during the life of the renowned Spinola, the Spanish arms long maintained an ascendant: but in the maritime war which extended to the New World, the Dutch fleets were everywhere victorious over those of Spain; and the policy of Olivarez drew upon his country the temporary assaults of England as well as the more lasting hostilities of France. Directed by the genius of Richelieu, the energies of that monarchy were ably and successfully applied to humble the power of the House of Austria; and the ambitious projects of foreign dominion, which Olivarez had built up, crumbled one after another to the ground.

Meanwhile a dangerous insurrection in Catalonia, provoked by the imprudent measures of that minister, and the revolt of Portugal (A.D. 1640), were added to the distresses of the Spanish monarchy. Olivarez announced this last event to his master as a subject of congratulation: 'Sire, the duke of Braganza has had the madness to suffer himself to be proclaimed king of Portugal. His imprudence will bring a confiscation of twelve millions into your treasury.' Portugal was irrevocably lost by mismanagement and defeat to the Spanish crown; but Catalonia, after a desperate struggle of many years, was finally reduced to obedience. Olivarez, whom Philip IV. was himself at last compelled to recognise as the cause of these multiplied disasters, was disgraced in 1647, and was succeeded as prime minister by his nephew Don Louis de Haro, who however was neither attached to him nor disposed to imitate his measures.

In the following year (A.D. 1648) was concluded the peace of Westphalia, by which Philip IV., for himself and his successors, finally and formally renounced all claim of sovereignty over the Seven United Provinces. The war with France, which still continued for eleven years, and the reverses of which were increased by the league of England, under the protectorate of Cromwell, with France, was little else than one long train of loss and disgrace to Spain; and the peace of the Pyrenees (A.D. 1659), which closed the struggle, was only obtained by territorial sacrifices.

This treaty was also distinguished by the marriage of Maria Theresa, eldest daughter of Philip IV., to Louis XIV. of France, an event which, despite of the solemn renunciation of the French king, was destined to convey the crown of Spain to the house of Bourbon. After this pacification Philip continued his vain efforts to recover the crown of Portugal for some years; and his death, which occurred in 1665, is said to have been hastened through grief at the continued defeat of his troops by the Portuguese. He was a prince of some talents, and of upright intentions: but a propensity to pleasure, which Olivarez had artfully encouraged, immersed him in indolence; and these habits enervated his understanding and rendered him incapable of applying to business. He left one son, who succeeded him under the title of Charles II., and died childless; and two daughters, Maria Theresa, married to Louis XIV., and Margaret Theresa, who became the wife of the emperor Leopold.

PHILIP V., king of Spain, was great-grandson of Philip IV., through his daughter Maria Theresa, grandson of Louis XIV. of France, and second son of the dauphin. He was born in 1683, received the title of duke of Anjou in his infancy, and was called by the last testament of Charles II. to the throne of Spain and the Indies in the the year 1700. The circumstances which attended this inheritance, and produced the memorable war of the Spanish succession, belong more appropriately to the reign of his grandfather [LOUIS XIV.]; and it will suffice in this place to sketch the principal events of his life after his recognition as king of Spain by the treaty of Utrecht (A.D. 1713). He had married, two years before, Maria Louisa, a princess of Savoy, to whom he became so tenderly attached that on her death (A.D. 1714) he abandoned for a time all care of business, and resigned himself to the guidance of the celebrated princess Des Ursins, a French woman of spirit and intelligence, the favourite of the deceased queen, who had accompanied her into Spain from Italy, and retained equal influence after her death on the mind of Philip. He desired to follow her advice in the choice of a second consort, and she was induced by Alberoni, an Italian priest, to select for his queen Elizabeth Farnese, daughter of the duke of Parma. But the new queen proved of a very different character from that which Alberoni had artfully ascribed to her; and instead of exhibiting the pliant temper and feeble mind which the princess Des Ursins had been taught to expect and reckoned upon governing, her first act was to cause the astonished favourite to be sent out of the kingdom.

Alberoni succeeded immediately to the influence of the discarded princess; was shortly appointed prime minister; and soon obtained from the pope the dignity of cardinal. This man, in whose mind there was much that was uncommon, and something of grandeur, had conceived the design of restoring Spain to her rank and power among nations. He began by the attempt to recover for her the Italian provinces, which had been lost by the treaty of Utrecht: but this, though only a part of the vast schemes which he had formed, was sufficient to alarm the leading powers of Europe; and it produced the quadruple alliance of England, France, the Empire, and Holland (A.D. 1718), which Spain was unable to withstand. Philip yielded to the demands of the allies by disgracing and banishing Alberoni, under the prudence and vigour of whose brief domestic administration agriculture and commerce had already begun to revive in Spain. A few years later, Philip, who, though not without some talents, was of a weak and melancholy disposition, abdicated his crown in favour of his son Louis (A.D. 1724), and retired with his queen to a religious seclusion at St. Ildefonso. But on the death of Louis, who, in a few months after his accession, fell a victim to the small-pox, Philip found himself compelled to resume the toils of government.

The period of his second reign, which was protracted for twenty-two years after his son's death, was occupied chiefly in obtaining possessions in Italy for his two sons by his ambitious queen Elizabeth Farnese, both of whom she succeeded in establishing in that country, Don Carlos as king of the Two Sicilies, and Don Philip as duke of Parma and Piacenza. In other respects the transactions of this long reign present nothing remarkable which does not belong to the general history of Europe rather than to that of Spain; and Philip died in 1746, leaving an only surviving son by his first wife, who succeeded him under the title of Ferdinand VI., and a numerous family by his second queen, one of whom, Don Carlos, afterwards ascended the Spanish throne as Charles III.

(For these reigns of the five Philips of Spain we have consulted *L'Art de vérifier les Dates*; the *Universal History* (vols. xvii., xviii.); Schiller, *Geschichte des Abfalls der Niederlande*; Watson, *History of the Reigns of Philip II. and Philip III.*; Coxe, *Memoirs of the Kings of Spain of the House of Bourbon*, &c.)

PHILIP OF ORLEANS, Regent. [ORLEANS, HOUSE OF.]

PHILIPPE I., king of France, son of Henri I., and third both in descent and succession from Hugues Capet, founder of the third dynasty of France, was born A.D. 1053, and succeeded his father A.D. 1060. His mother was Anne of Russia, daughter of the Czar Jaroslaf I. On his deathbed, Henri committed the care of the child and the administration of the government to his brother-in-law, Baudouin or Baldwin, count of Flanders. Baudouin did little more till the time of his death (A.D. 1067) than occasionally visit his ward, who was brought up sometimes at Paris, sometimes at one or other of the royal castles. The death of Baudouin removed from Philippe the restraint which his station and inexperience required, and he plunged into a series of excesses of the most disgraceful character. The means of indulgence were supplied from various sources, especially from the sale of ecclesiastical benefices and dignities, which subsequently drew upon him the hostility of the church, but although he had not sufficient energy vigorously to struggle against the growing spirit of ecclesiastical domination, his necessities and his profligacy prevented his entire submission to the claims of the popes, who desired to engross to themselves all the higher ecclesiastical appointments. Philippe was engaged, not long after the death of Baudouin, in a war with Robert le Frison, or the Frisian, who had usurped the county of Flanders from his nephew Arnolphe, the grandson of Baudouin. The hasty and inadequate force assembled by Philippe was surprised and routed by Robert near Cassel: the young Count Arnolphe was killed, and the king only saved himself by a hasty and inglorious flight (A.D. 1071). In a second attempt to subdue Robert, Philippe met with no better success. He then made peace with him, and married Bertha of Holland, his step-daughter.

From 1075 to 1087, Philippe was engaged in occasional hostilities with Guillaume, or William, duke of Normandie, and king of England, which kingdom he had acquired by conquest (in 1066) during Philippe's minority. But the war was languidly conducted, on the part of Philippe from indolence, and on that of William from full occupation in other quarters, and perhaps from the feudal sentiment of respect for his suzerain. Philippe however encouraged the discontented vassals and rebellious children of William; and the contest did not finally terminate until the death of the Conqueror (A.D. 1087). He had become excessively corpulent, and a coarse jest of Philippe, who inquired 'when he would be put to bed,' excited his indignation. 'When I go to be churched at St. Géneviève, I will offer a hundred thousand tapers,' was the reply of the angry veteran. He entered the territory of Vexin, and stormed Mantes; but a hurt which he received by his horse falling proved mortal, and relieved Philippe from his hostility.

The year 1092 was marked by the most important incident of Philippe's life. He had become weary of his wife Bertha, by whom he had four children, and had confined her in the castle of Montreuil, which had been settled on her by way of dower. He now married Bertrade, wife of Foulques le Rechin, count of Anjou, who, dreading her husband's inconstancy, forsook him and took refuge with Philippe. This marriage was so glaringly inconsistent, not only with good morals and decency, but with ecclesiastical law, that it was with difficulty that any bishop could be procured to solemnise the union. It involved Philippe in two wars, one with Robert le Frison, who took up the cause of the repudiated Bertha; and another with Foulques of Anjou, who sought to recover Bertrade. The church also took up the matter, and Philippe was daily attacked with remonstrances, censures, and threats of excommunication. In return he threatened the bishops, and even subjected one of them to a short imprisonment. Philippe had obstinacy enough to retain Bertrade, but not sufficient strength of character to silence the bishops. Some of them indeed embraced his cause, after the death of his injured wife Bertha (A.D. 1094), and, in a council held at Reims, showed a disposition to attack the bishop of Chartres, his sturdiest opponent. But the majority of the French bishops, in a national council at Autun, excommunicated both Philippe and Bertrade (A.D. 1094). The pope, Urban II., despising his weakness, thought it not necessary to pursue him to extremity, and the sentence was only so far enforced as to deprive him of the liberty of wearing the ensigns of royalty, and to prevent the celebration of public worship in the place where he was. He retained the exercise of such power as he possessed, and was allowed to perform his devotions in his private chapel.

Near the close of the eleventh or the beginning of the twelfth century, Philippe, being engaged in hostilities with William II., the Red, who then held Normandie, associated with himself in the honours and powers of royalty his son Louis VI., then only eighteen or twenty years of age, afterwards known as Louis le Gros. The activity and good conduct of the prince gradually raised the royal power from the contempt into which it had fallen, but excited the jealousy of his step-mother Bertrade. The court was divided; Louis is charged with seeking a pretext to have Bertrade murdered, and Bertrade practised on his life by poison. Neither the divisions of his family nor the power of the church could prevail on Philippe really to put away Bertrade, or to deprive her of the title of queen. A declaration of penitence, an engagement no longer to regard her or live with her as a wife, which engagement he afterwards openly violated, were accepted by the church, and the excommunication was taken off (A.D. 1104). Bertrade afterwards succeeded in reconciling both herself and Philippe with her former husband, Foulques le Rechin, and the degrading intercourse of the two husbands of this infamous woman is described by Sismondi after Orderic Vitalis. The remaining years of Philippe were marked by little except the intrigues of Bertrade for the advancement of her children by both marriages. In 1106, Constance, daughter of Philippe by his first wife, married Boemond, or Bohemond, the Norman, prince of Antioch, who had come to France in discharge of a vow, and to raise recruits for the Holy Land.

Philippe died at Melun, of premature old age, the result of his intemperance, A.D. 1108, having nearly completed the forty-eighth year of his reign, and was succeeded by Louis VI. His worthless character, combined with the low state of the regal power, rendered him a spectator rather than an actor in the events of his reign. France possessed at this time little national unity, and the history of the time is the history of the great nobles and of the provinces, rather than the history of the king or the kingdom. From the time of Philippe the royal power revived. The activity of Louis had given an impulse to it even in his father's time, and his activity and that of his immediate successors gave permanence to the movement.

PHILIPPE II., better known as **PHILIPPE AUGUSTE** (a name which he is thought to have derived from being born in the month of August), was the son of Louis VII., surnamed Le Jeune, or the Young, and Alix, daughter of Thibaut le Grand, count of Champagne, his third wife. He was born A.D. 1165, and was crowned at Reims, when little more than fourteen years of age, in his father's lifetime, upon whose death, in the following year (A.D. 1180), he came to the throne. He had however exercised the sovereign power from his first coronation, his father being disabled by palsy, and one of his earliest acts was a general persecution of the Jews, whom, when assembled in their synagogues on the Sabbath, he caused to be surrounded by soldiers, dragged to prison, and despoiled of all the gold and silver that was found on them. He also published an edict, by which all debts due to them were to be annulled on condition that the debtor should pay to the royal treasury a fifth part of the amount due. Other acts of persecution followed, and in 1181, the Jews were commanded to dispose of all their moveable property and quit the kingdom for ever; all their real property was confiscated to the crown, and their synagogues were ordered to be converted into Christian churches. The intercession both of nobles and ecclesiastics, for whose good offices they paid large sums, was in vain; and after experiencing a heavy loss from the enforced sale of their effects, they were expelled from all the domains of the crown. The great vassals of the crown were in no hurry to repeat the royal edict, and in the county of Toulouse especially the Jews remained undisturbed. Other acts of persecution followed, and the king is recorded 'not to have allowed to live in all his kingdom a single individual who ventured to gainsay the laws of the church, or to depart from one of the articles of the Catholic faith, or to deny the sacraments.'

The pride and ambition of Philippe led him, even before his father's death, to embroil himself with the queen his mother and her four brothers, the counts of Blois, Champagne, and Sancerre, and the archbishop of Reims, who had taken advantage of the weakness of Louis VII. to govern France in his name, and who concluded that it belonged to them to direct the administration of a minor king. The good offices of Henry II. of England arranged the dispute. Philippe married, before his father's death, Isabelle, niece of the count of Flanders, his godfather; and was, with her, crowned a second time at St. Denis, by the archbishop of Sens. This marriage was one of the causes of dispute with his mother and uncles. He soon alienated the count of Flanders, as well as most of the other great vassals of the crown, who united to oppose his rising power; but the good offices of Henry of England again restored quiet (A.D. 1182). It was a little after this that he caused some of the streets of Paris to be paved. [Paris.] After an interval of three years (A.D. 1185), war between Philippe and the count of Flanders again broke out, and ended, after a short campaign, by a peace which added to the territory and resources of the king. A struggle with the duke of Bourgogne (A.D. 1186) also terminated favourably for the king. Hostilities with Henry II. of England followed, and were attended with success; and that powerful monarch, broken-hearted at seeing his own sons in league with his enemy, died at Chinon (A.D. 1189).

In A.D. 1188 Philippe had taken the cross. In 1190 the combined forces of Philippe and Richard I. of England rendezvoused at Vezelay, not far from Auxerre; and in the autumn of the same year they embarked, Philippe at Genoa, and Richard at Marseille. They met and wintered at Messina in Sicily, and in 1191 proceeded to the Holy Land; but before long, Philippe, jealous of the superiority of Richard as a warrior, made ill health an excuse for returning to France, and reached Paris in December, 1191. He had left his mother Alix, and his uncle, the archbishop of Reims, regents of his kingdom. The incidents of the crusade had made Philippe and Richard rivals; and the former, on his return, commenced his attack on the other, at first by intrigues, and afterwards by force. He made some acquisitions in Normandie, but failed (A.D. 1194) in attacking Rouen. The following years were occupied with alternate periods of truce and hostility, in which the policy and steadiness and the feudal superiority of the French king rendered him a match for the more soldier-like qualities of Richard; and on the death of Richard (A.D. 1199), the incapacity of John, his successor, enabled Philippe to establish decisively the superiority of the Capet race over the rival family of Plantagenet. During this war, Philippe, now a widower, married Ingeburge, or Isamburge, sister of Canute VI., king of Denmark (A.D. 1193); but having in a short time obtained a divorce in an assembly of prelates and barons, he married Marie, or Agnes, daughter of Berchtold, duke of Merania, a German noble (A.D. 1196), in contempt of the authority of the pope, before whom the case of Ingeburge had been carried, and by whom the divorce had been annulled. The struggle between the king and the pope (Innocent III.) continued for some years, until an interdict laid on Philippe's dominions obliged the king to submit the affair to an ecclesiastical council at Soissons (A.D. 1201); but he evaded their decision by a pretended reconciliation with his queen Ingeburge, whose real condition was however little improved. Marie of Merania, from whom he had been obliged to separate himself, died soon after, leaving two children, whom the pope did not scruple to declare legitimate.

The murder of Arthur of Bretagne, by his uncle John of England, having roused general indignation, Philippe seized the occasion to attack Guienne, Normandie, Touraine, Anjou, and Poitou. These, except Guienne, he speedily conquered; and prosecuting John before the court of the twelve peers of France, by a sentence quite unprecedented in France and unauthorised in such a case by the institutions of feudalism, procured the confiscation of all his French dominions (A.D. 1205). Crimes, however flagrant, which did not violate the duty of the noble to his feudal superior, had not hitherto been cognizable in the great feudatories; and the Court of Peers, which Philippe professed to revive from the institutions of Charlemagne, was probably an innovation, founded on romances to which the ignorance of the age gave the credit of being faithful historical traditions. It consisted of twelve members, viz.: six of the great nobles (the dukes of Normandie, Bourgogne, and Aquitaine; and the counts of Toulouse, Flanders, and Vermandois, for the last of whom the count of Champagne was substituted), and six prelates, by means of whom the king sought to influence the decisions of the tribunal. As in judgments involving a capital sentence the ecclesiastics could not take part, it is probable that the number of twelve was made up out of the higher nobility who were at court at the time. The nobles forming the court, proud of sitting in judgment on a crowned head, lent themselves to the purpose of Philippe, who met with no opposition in thus establishing a jurisdiction which might hereafter promote the aggrandisement of the crown. John succeeded in preserving Guienne and recovering Poitou and part of Touraine; but Normandie, and his other dominions to the north of the Loire were finally lost.

In the interval of peace which followed, Philippe endeavoured to consolidate the institutions of his kingdom by holding national assemblies; but his authority in the south of France, where the crusade against the Albigeois was about this time (A.D. 1207, 1213) carried on, continued to be merely nominal. He embellished Paris, protected the university of that city, and sought the favour of the church by sending to the stake those charged with heresy. Under pretence of supporting the cause of the church against John of England, Philippe prepared for the invasion of that kingdom; and when John had submitted to the church, under the protection of which he placed himself, Philippe turned his arms against Flanders, the count of which had refused to join in the invasion of England. He obliged the chief towns to surrender, and committed great ravages; but lost his fleet, part of which was taken by the English, and the rest burnt in the port of Dam to prevent its falling into their hands (A.D. 1213). Next year Philippe was attacked on the side of Poitou by John, and on that of Flanders by the Flemish nobles and burghers, supported by the emperor Otho IV.; but John was repelled by Louis, the son of Philippe; and the emperor, whose army consisted almost entirely of Flemings, was defeated by Philippe himself at Bouvines, between Lille and Tournay (A.D. 1214).

In 1216, Louis, son of Philippe, went over to England, whither he was invited by the malcontent barons; but he was obliged to return the next year. In 1219 he took part in the crusade against the Albigeois; and was afterwards (A.D. 1221) engaged in hostilities in the provinces held by the English king Henry III. The Count of Montfort, unable to retain the conquests which his father, Simon de Montfort, had made in the county of Toulouse [Languedoc], offered to cede them all to Philippe Auguste; but the king, who had never taken much interest in the affairs of the south, declined engaging in the negotiation. The feebleness of his health increased the natural caution of age, and he took little part in the affairs of foreign lands. He employed himself chiefly in strengthening and improving the domains of the crown, which he had so widely extended; and he walled in the towns and villages which it comprehended. His regular management of his revenues enabled him to effect this, and yet to bequeath to his various legatees an immense sum, of which the maxims of the time enabled him to dispose as if it had been his own property. He died at Mantes, A.D. 1223, in the fifty-eighth year of his age, having reigned forty-three years.

PHILIPPE III., surnamed **LE HARDI**, or the Bold, was the eldest son of Louis IX. (or St. Louis). He was born in May, A.D. 1245; and was proclaimed king in the camp before Tunis, which city his father was besieging at the time of his death, August, A.D. 1270. The army remained yet two months in Africa, suffering much from the climate: at length peace was made with the king of Tunis; and part of the besiegers determined to proceed with Alphonse, count of Poitou and Toulouse, the king's uncle, to the Holy Land; another part with Charles of Anjou, another of his uncles, for Constantinople; while the remainder, under Philippe himself, were to return to France. Before their final separation, the division destined for the Holy Land was shattered by a tempest, and many vessels were lost. The expeditions to the Holy Land and to Constantinople were consequently given up, except by an auxiliary division of English, which proceeded under Prince Edward (afterwards Edward I.) to Acre; and the wreck of the army, diminished by sickness, proceeded with Philippe to France. His father and one of his brothers had died at Tunis, and he lost, on his way through Sicily and Italy, his brother-in-law, the king of Navarre, through disease, and his wife, Isabella of Aragon, who died through premature childbirth, the consequence of a fall. It was not till May 21st, 1271, that he reached Paris. He was crowned at Reims in the following August, and shortly after, by the death of his uncle Alphonse, acquired the counties of Poitiers and Toulouse, which that prince had possessed.

It was the object of Philippe to render the great feudal nobles more completely subject to his sceptre, and he reduced to subjection the count of Foix, who had refused obedience to his commands (A.D. 1272). He married (A.D. 1274) Marie, daughter of the duke of Brabant, who was crowned as queen the following year. He interfered in the affairs of Navarre, during the minority of his kinswoman Jeanne, heiress of that kingdom, who was designed to be married to one of his sons; and in the affairs of Castile, to support the claims of the Infants of La Cerda, his sister's children, and heirs in the direct line to that kingdom, whom the Cortes had set aside in favour of Sanchez, their maternal uncle. He succeeded in retaining Navarre for some years, but his projects in Castile failed of success.

During the earlier years of his reign Philippe was much under the influence of Pierre de la Brosse, who had commenced his career at court as barber-surgeon to Saint Louis, and had risen to the rank of chamberlain. His elevation, and the abuse, real or supposed, of his influence over the king, caused his downfal; he was arrested (A.D. 1278), tried on some charge never promulgated, before a commission of nobles, condemned to be hung, and executed in pursuance of his sentence. The immediate cause of his downfal is supposed to have been his inspiring Philippe with a suspicion that his Queen, Marie of Brabant, had poisoned her step-son Louis, Philippe's eldest son by his first wife, in order to open a way for her own children to the succession.

In 1283 Philippe engaged in war with Pedro, king of Aragon; the crown of which kingdom had been offered by the pope (who had excommuncated Pedro) to Charles of Valois, Philippe's second son, to be held in feudal subjection to the holy see. The French king assembled his barons and prelates to deliberate on the matter, and by their advice accepted the pope's offer. The prelates and nobles formed on this occasion two separate chambers. In 1285 he invaded Catalonia, took the town of Elna by assault and massacred the inhabitants, compelled Rosas and Figueras to submit, fought an indecisive battle at Hostalrich, and took Gerona by capitulation. But the long siege and severe loss which this last-mentioned town had cost him, the superiority of the Aragonese and Sicilians by sea, and the wasting of his army by disease, compelled him to commence a retreat, which he did not effect without considerable loss. Philippe was himself seized by the disease which had wasted his army, and died, on his return to France, at Perpignan, 5th October, A.D. 1285.

PHILIPPE IV., better known as **PHILIPPE LE BEL**, son of Philippe le Hardi, by his first wife, Isabella of Aragon, was born A.D. 1268; and succeeded his father on the throne of France, October, A.D. 1285, having previously acquired, in right of his wife Jeanne, the crown of Navarre. He was crowned at Reims, January, 1286. The war with Aragon continued, but was carried on languidly. The young king gave, from the first, his confidence to the lawyers, who were gradually working the overthrow of the feudal system, and giving consistency and stability to a system of jurisprudence favourable to despotism; they flattered him, by describing his power as absolute; and inspired him with mistrust both of the dignified clergy and of the nobles, whom they looked upon as rival classes to themselves. It is likely that in the earlier period of his reign he indulged the love of luxury and refinement then prevalent; though this appears, not from direct testimony, but from his continual poverty, In 1290 he despoiled the Jews; and in 1291 he ordered the Italian merchants, who engrossed nearly all the commerce of his kingdom, to be imprisoned; and by the apprehensions of further violence, with which he inspired them, induced them to ransom themselves by heavy payments. Most of them speedily quitted the kingdom. Two brothers, Florentines, Biccio and Musciatto Franzesi, are supposed to have prompted Philippe to this deed of violence and injustice, by which they not only filled the king's coffers, but acquired for themselves the monopoly of the French markets. The success of these experiments encouraged the king to make the lawyers the instruments of his exactions; his policy in fact nearly resembled that pursued at a later period by our own Henry VII.; and had a like effect in amassing wealth and in depressing the power of the nobility.

In 1290 Philippe paid a visit to the south of France, in order to form with his allies a plan of combined operations against Aragon, to confirm his authority over his remote vassals at the foot of the Pyrenees, and to gain the affections of the nobles of Guienne, then subject to Edward I. of England, of whom Philippe began to be jealous. In 1291 he proposed to renew the attack upon Aragon, refusing to ratify the treaty which had been concluded by the other belligerent parties at Tarascon in the early part of the year: but the proposal was probably a mere feint to raise money. In this point too the policy of Philippe bears a close resemblance to that of Henry VII.

In 1292 a quarrel between some English and Norman sailors at Bayonne, followed by mutual hostilities between the vessels of the Cinque Ports and France, ripened the jealousy of Philippe into determined hostility to Edward. He summoned the latter, under certain penalties, to appear before the parliament at Paris (A.D. 1293), to answer for the hostilities committed by his vassals; and Edward, observant of his subordination as a vassal of the king of France, obeyed the summons by sending his brother Edmond to appear for him (A.D. 1294). Anxious to avoid a continental war, he consented to deliver up six towns in Guienne to commissioners appointed by Philippe; and to surrender twenty of the persons most deeply implicated in the previous hostilities, to take their trial before the parliament of Paris. Instead of six towns, Philippe caused the whole of Guienne to be occupied by an armed force; and when he had thus obtained possession, he charged Edward with contumacy, and cited him again before the parliament, under heavier penalties for non-appearance than before. Enraged at being thus outwitted, the English monarch renounced his allegiance, sent an army to recover Guienne (A.D. 1295), and formed alliances with various continental princes against Philippe. But the war was languidly carried on, for Edward's attention was engrossed by Scottish affairs, and his continental allies made few efforts, except the Flemings, who were unfortunate. Hostilities were terminated by a truce of indefinite length, and by the arrangement of some matrimonial alliances between the two royal houses, concluded by the mediation of the pope Boniface VIII. (A.D. 1298.) By the terms of this truce, part of Guienne was restored to Edward, but the final adjudication of that great fief was reserved for the future decision of the pope. The expenses of this war increased the necessities of Philippe, and these led him into disputes with the clergy and the pope, and made him persecute the Jews in order to extort from them a portion of their wealth. One beneficial result sprang from his desire of money—he emancipated the serfs of Languedoc, commuting his rights over them for a pecuniary payment.

Philippe was anxious to avenge himself on the princes who had allied themselves with Edward. The defeat and death of Adolphus of Nassau, king of the Romans, may be ascribed to his intrigues (A.D. 1298). The count of Flanders was imprisoned and his county seized; but the oppressions of the French caused a revolt of the Flemings, in attempting to suppress which the French suffered a complete defeat at Courtrai (A.D. 1302). Philippe advanced next year into Flanders with a vast army, but effected nothing; and in order to have his hands free for this war, and for a dispute with the pope, which he had been long carrying on, he made a definitive peace with Edward of England, to whom he restored the whole of Guienne (A.D. 1303). He advanced into Flanders, defeated the Flemings both by sea and land (A.D. 1304), but found still so obstinate a resistance, that he made peace, contenting himself with the cession of a small part of the country, and conceding the independence of the rest. The pope had meanwhile been seized by Nogaret, Philippe's envoy at Anagni; and though released by the populace, had died about a month after of a fever, the result probably of the agitation to which he had been exposed. (A.D. 1303.) Benedict XI., who succeeded him, lived but a short time, and on his death the pontificate came to Clement V. (A.D. 1305). The exactions and the depreciation of the coinage, by which Philippe provided resources for the Flemish war, provoked discontent in various parts of his dominions, which he endeavoured to suppress by merciless severity. The seizure and banishment of the Jews of Languedoc, and the confiscation of their property, was another of the measures to which he had recourse at this time (A.D. 1306).

Among the methods which Philippe employed to fill his exchequer, the depreciation of the coinage had been one of the most usual. He had paid in this depreciated coinage the sums he had borrowed in a currency three times more valuable. When however he found that his plan began to tell against himself, his revenues being paid in the depreciated coinage, he found it necessary to correct the abuse, and to issue money equal in value to that of previous reigns. This however caused fresh disturbances; debts contracted in the depreciated money had now to be paid in the new and more valuable coinage; and this hardship led to commotions, which Philippe repressed with atrocious cruelty. He found it necessary however to publish some new edicts, in order to remedy the evil complained of (A.D. 1305). In order to conciliate the nobility, whose alliance he wished to make a counterpoise to the popular discontent, Philippe restored the practice of judicial combat in all heavier accusations against the nobility.

It was probably the desire of Philippe to obtain their wealth, that led to the suppression of the great military order of the Templars. They were accused of crimes the most revolting by two worthless members of their own order; and Philippe gave secret orders for the arrest of all who were in France; and these orders were executed in all parts of his dominions at the same time. The trials were carried on before diocesan tribunals; and though the pope (who was a creature of Philippe) at first claimed for himself the investigation of charges affecting an ecclesiastical body, he gave up the point, reserving to himself only the trial of the grand-master and a few other chief men. The judges were eager to convict the accused: confessions were wrung from many by torture; numbers were brought to the stake for denying the confessions thus extorted; others were condemned to various inferior penalties. The persecution became general in Europe, but out of France the Templars were generally acquitted of the charges brought against them. The pope however, at the instance of a council assembled at Vienne, suppressed the order by virtue of his papal authority, and granted their possessions to the Hospitallers (A.D. 1311). But Philippe and his nobles had already seized their French possessions, and the Hospitallers were obliged to redeem them with heavy payments. Jacques de Molay, grand-master of the Templars, and the commander of Normandie, were burnt at Paris for retracting their confessions (A.D. 1314).

The last years of Philippe's reign were signalised by these infamous proceedings. He managed about the same time (A.D. 1310) to gain possession of Lyon, which had previously enjoyed a considerable degree of independence, though nominally subject to the empire. [Lyon] He also interfered as mediator (A.D. 1313) between Edward II. of England, who had married his daughter Isabelle, and the discontented barons of that kingdom. His necessities induced him to persecute afresh the Jews and the Lombard merchants; and his severe and suspicious temper led him to reiterated cruelties. The wives of his three sons were charged with adultery, and two of them were declared guilty, and condemned to imprisonment; while their lovers, and those who were supposed to have aided in their crimes, were put to death by the most horrid tortures. The wife of Philippe, count of Poitiers, his second son, was acquitted (A.D. 1314).

Philippe le Bel died at Fontainebleau, from the effect of an accidental fall while hunting, 29th of November, 1314, in the thirtieth year of his reign, and the forty-sixth of his age.

It was in the reign of Philippe le Bel that the *Tiers Etat*, or commons, were admitted for the first time to take part in the national assemblies subsequently designated *les Etats Généraux*, or *States-General*. They were present at a council held (A.D. 1302) on occasion of Philippe's dispute with the pope Boniface VIII. It was in this reign also that the sittings of the parliament, the supreme justiciary court, into which, by the substitution of the lawyers for the nobles, the antient Cour de Pairs [Philippe II.] had been transformed, became fixed at Paris.

PHILIPPE V., known as **PHILIPPE LE LONG**, the second son of Philippe IV., or 'Le Bel,' was born A.D. 1294, and succeeded to the throne A.D. 1316. His elder brother, Louis X., or Louis le Hutin, had died 5th of June, 1316, leaving by his first wife a daughter, who succeeded him on the throne of Navarre, and his queen, who was his second wife, pregnant. On the news of his brother's death, Philippe, who was at Lyon, where the conclave of cardinals were engaged in the election of a pope, hastened to Paris, and assumed the government, which was confirmed to him by the barons of the kingdom, who were assembled for the purpose, until the birth of the child, of which the widowed queen was then pregnant. If she produced a son, he was to retain the government as regent during the minority of the child; if a daughter, he was to be recognised as king. The child, which was a boy, died a few days after birth (November, 1316), and Philippe assumed the sovereignty in full right, and was crowned at Reims, Jan. 9th, 1317.

It was upon this occasion that the Salic law, by which females were excluded from the succession to the throne, was established as a constitutional law in France. Louis X. had left a daughter, Jeanne, queen of Navarre; and there appears to have been no just ground, either from precedent or from the analogy of the laws of succession which prevailed in other kingdoms, or in the great fiefs, for her exclusion. The ground urged by the legal supporters of Philippe's claim was an antient law excluding females from the succession to the Salic lands, a peculiar species of allodial possessions, but which law could only by a remote analogy be made to bear on the succession to the throne. The case of a sole heiress to the crown had not however occurred before; and if there was no precedent for the exclusion of a female, there was no instance of one having really occupied the throne. Jeanne was, besides, a female and a minor: the duke of Bourgogne, her maternal uncle, who was her natural supporter, was induced to surrender her claim; the States-General, being convoked, confirmed the title of Philippe; and the death of his only son induced his brother Charles to assent to it, in the hope of turning against Philippe's own daughters the law of which he was desirous to avail himself to the exclusion of his niece. The Salic law was thus firmly established as the fundamental law of succession in the French monarchy.

The States-General were assembled three times in this reign; first to confirm Philippe's title to the throne, then to regulate the finances, and lastly for a general reform of abuses. In the first of these assemblies Philippe issued an edict, giving a military organization to the communes, though he was subsequently obliged, by the jealousy of the nobility, to make some modifications in it. Another of his edicts revoked the grants made by his father and brother from the royal domain, and became the foundation of the constitutional principle that that domain was inalienable. In other edicts he gave increased regularity to the legal and fiscal institutions which were gradually superseding the arrangements of the feudal system. These edicts were issued by the king as from himself, and the States-General were carefully precluded from the exercise of any properly legislative functions.

The south of France was during this reign the scene of cruel persecutions, directed by the influence of the pope, John XXII., against those accused of sorcery and against the Franciscan monks. In 1320 an immense body of the French peasantry assembled from all parts for a crusade, attracted by two priests, who preached that the deliverance of Jerusalem was reserved not for the high-born and noble, but for the meek and lowly. They soon became disorderly, and perpetrated the most merciless outrages on the Jews, until they were put down by force, or died of famine and disease. The most fearful severities were exercised against those of them who were taken. In 1321 a dreadful persecution was directed against those afflicted with leprosy (a disease which the crusaders had brought from the East), on a charge of having poisoned the wells; and also against the Jews, on a charge of having instigated them. A hundred and sixty Jews of both sexes were burnt in one fire at Chinon near Tours; others were banished and their goods confiscated. It was while engaged in these cruel proceedings that Philippe le Long died, Jan. 3, 1322, at Longchamps near Paris, after a reign of rather more than five years. He left four daughters; but the Salic law excluded them from the throne, and he was succeeded by his brother Charles IV., or Charles le Bel.

PHILIPPE VI., or, as he is usually called, **PHILIPPE DE VALOIS**, succeeded to the throne shortly after the death of Charles IV. le Bel (A.D. 1328), and was the first king of the collateral branch of Valois. He was son of Charles, count of Valois, a younger son of Philippe III. le Hardi, and cousin to Louis X. le Hutin, Philippe le Long, and Charles le Bel, who successively wore the crown. In the reign of Philippe le Long he had headed an expedition of the nobles and gentry of France to overthrow some chieftains of the Ghibelin party in Lombardy. His presumption and incapacity involved him in difficulties, from which he was relieved only by the policy or generosity of his opponents, who allowed him to retire with his army into France (A.D. 1320).

Charles le Bel died Feb. 1, 1328, and left no male heirs; but his widow was pregnant, and the nobles of the kingdom determined to wait the result of her confinement; and in the mean time the sovereign power, with the title of regent, was confided to Philippe de Valois. When the queen was delivered of a daughter (April 1), the right of succession was far from clear. All the doctors of civil and canon law agreed that women were excluded from the succession; but they were divided on the question whether a woman, being disqualified merely by sex, might transmit a right to her descendants, just as a lunatic or an idiot might be supposed to do; or whether the disqualification affected not only the woman herself, but all who might otherwise have derived a claim through her. But however the lawyers might agree as to the exclusion of females, the operation of the Salic law had been too recent, and too obviously the result (in part at least) of the superior power of the male claimant, to be entirely satisfactory to the public mind, or to those whose interests were concerned in the dispute; and Philippe, count of Evreux, who had married the daughter and heiress of Louis le Hutin, and was, in right of his wife, the nearest in direct succession, might have been a powerful rival, had he not readily exchanged a right of so doubtful a character for the peaceful possession of the throne of Navarre. The daughters of Philippe le Long and Charles le Bel, all yet in childhood, wanted either the inclination or the power to advance their claims against so formidable a competitor as Philippe de Valois; and Edward III. of England, who was next in succession, as being son of Isabelle, sister of the last three kings, was as yet also a minor, and too closely beset with difficulties at home to think of serious measures to vindicate his claim. The power therefore of Philippe as regent, his mature age, his large hereditary possessions, and his popular character, added to the plausibility of his claim, as the nearest male heir claiming through male ancestors, enabled him quietly to ascend the throne. He was crowned at Reims, May 29, 1328. Isabelle, in the name of her son Edward III., protested against this invasion of his rights; but as Edward did homage to Philippe the next year for Guienne, he may be considered as having renounced his claim, which would probably never have been revived but for subsequent events.

The first important enterprise of Philippe after his coronation was an expedition into Flanders, to put down the burghers of the great towns, who had revolted against their count. The Flemings surprised him in his camp at Cassel, but were defeated with great slaughter (Aug. 23, 1328), and Philippe returned to France with all the glory of victory. The early years of his reign were also occupied in regulating the coinage by successive edicts, in settling the boundaries of the civil and ecclesiastical jurisdictions, and in determining the succession to the county of Artois. This was claimed by Robert, count of Beaumont, more familiarly known as Robert of Artois, against his aunt Mahaut, who had usurped the county in his minority, and had been confirmed in possession by the parliament of Paris, influenced by the king Philippe le Bel. Robert had subsequently tried to obtain his right both by force and by legal process, but was defeated. He now (A.D. 1330) made another attempt with more favourable prospects, but was again defeated, and banished the kingdom for having forged some documents in support of his claim. He subsequently retired into England (A.D. 1333), and instigated Edward III. to renew his claim to the French throne.

A crusade against the Moors of Granada was a favourite project of Philippe; but the concessions which he demanded of the pope, as the price of his services in this affair, were too exorbitant, and the project failed (A.D. 1332). He also sent assistance to David Bruce, king of Scotland, against Edward III, and afforded him a refuge at his court: these measures, and disputes which arose in Guienne, tended to hasten the approaching rupture between France and England. He renewed his project of a crusade, and visited the pope, Benedict XII., at Avignon (A.D. 1336), but the project never took effect; and he endeavoured to obtain by exchange possession of the duchy of Bretagne; but this plan also failed. At length (A.D. 1337) war between Edward III. and Philippe broke out. The former assumed the title of king of France, and formed an alliance with the Flemish burghers, at that time under the influence of James Arteveld of Ghent. His fleet took and destroyed Cadsand (A D. 1337), and he made two fruitless campaigns on the side of Flanders (A.D. 1338, 1339). In 1340, the French, first under Jean, son of Philippe de Valois, and then under the king in person, attacked Hainault, the count of which was in alliance with Edward; but the defeat of the French fleet at Sluys (June 24th), induced Philippe to retire; and after some other hostilities, an armistice of six months was concluded.

Our limits do not allow us to particularise the incidents of the struggle which was carried on, both in Bretagne, where Edward and Philippe engaged as auxiliaries [BRETAGNE], and in other parts. In the course of it, Philippe sought to obtain money by depreciating the coinage (A.D. 1342), and by establishing the gabelle, or government monopoly of salt (A.D. 1343). He violently and arbitrarily put to death some Breton and Norman gentlemen (A.D. 1343), and tampered repeatedly with the currency. Some regulations were issued (A.D. 1344) in order to revive commerce and regulate the administration of justice, the last almost the only acts of his reign that were really useful (A.D. 1344). He arrested the Lombard and other Italian merchants in his dominions, and confiscated their goods (A.D. 1347). The latter years of his reign were as unfortunate as his measures were unjust. He sustained a great defeat at Crécy (A.D. 1346) [CRECY]; lost Calais, the key of his kingdom on the side of England (A.D. 1347) [CALAIS]; and was unsuccessful on the side of Guienne and Poitou (A.D. 1345, 1347). A dreadful pestilence, which swept away a third part of his subjects (A.D. 1348), filled up the measure of his adversity. The acquisition of the district of Viennois, ceded to him by the dauphin or lord of that country [DAUPHINE], was a poor counterbalance to these calamities.

The death of Philippe was owing to debility, the result of an unseasonable marriage with the princess Blanche of Navarre, a girl of eighteen, who had been promised to Jean, Philippe's eldest son. During Jean's absence, the king married her himself. He died at Nogent-le-Roi, near Chartres, Aug. 22, 1350, in the fifty-seventh year of his age, and the twenty-third of his reign.

PHILIPPE (Dukes of Burgundy). [BOURGOGNE.]

PHILIPPI. [BRUTUS; MACEDONIA.]

PHILIPPIANS, EPISTLE TO THE, is one of the epistles written by St. Paul during his first imprisonment at Rome. [PAUL, ST.]

Like the other early churches planted out of Palestine, the church at Philippi in Macedonia consisted of Jews and Gentiles, the latter forming the larger portion. These Philippians must however have had cultivated minds, and have been acquainted with the manners, customs, and philosophy of the Greeks, since the epistle contains allusions the force of which no other persons could fully understand. They were first converted by the preaching of St. Paul about twelve years before the date of this epistle, which was written apparently but a short time before his release from his imprisonment at Rome, A.D. 63.

The occasion of its composure seems to have been the following:—the Philippians, having heard that St. Paul was a prisoner at Rome, sent contributions for his relief by the hand of Epaphroditus, whom Theodoret and others represent as their bishop. St. Paul, being much rejoiced by this proof of their affection towards him, and by learning how great was their proficiency in all Christian excellences, sends back Epaphroditus with this epistle.

In addition to the utterance of his joy on these accounts, he gives them admirable instructions for the purpose of fortifying them amidst their exposure to the scourge of persecution and the contagion of false teaching; and of exciting them to cultivate a oneness of thought and feeling, and ever to aim at higher measures of knowledge and obedience. These instructions he enforces by holding up the most ennobling views of the Christian religion, as affording its disciples a scope for leading a life at once contemplative and active, and so giving them the power of enjoying and diffusing substantial happiness.

In this epistle St. Paul discovers much of his own character, the traits of which cannot fail to create in the mind of an attentive reader an idea of true dignity. He delicately proposes his own conduct for the imitation of the Philippians, and, with no mixture of affected humility, he disclaims all personal merit for whatever wisdom or goodness they had seen in him or heard of him. His language is for the most part constructed with great skilfulness; his thoughts are arranged in an order exactly suited to his design; and his manner is at once affectionate and authoritative.

The canonical authority of this epistle has never been doubted. But because St. Polycarp speaks of St. Paul as having written to the Philippians *epistles*, some critics have thought that this is not the only epistle which they received from St. Paul, or that it was originally two. In reply to this it may be observed that instances from writers both Greek and Latin could easily be produced to show that the plural form of this word must sometimes be understood in the sense of *one epistle only;* and that there is no other reason to suppose that St. Polycarp referred to any writing but this epistle of St. Paul as we now find it.

(Theodoret and Bishop Fell *On St. Paul's Epistles;* Fabricius, *Bibliotheca Græca;* Schott, *Isagoge.*)

PHILIPPICS. [DEMOSTHENES.]

PHILI'PPIDES of Athens, a poet, and a writer of the new comedy, flourished about B.C. 335. He wrote forty-five plays, of which the titles of twelve are mentioned by antient authors. He died of joy at an advanced age, after he had obtained a prize which he did not expect. (Suidas, *Lexicon;* Fabricius, *Bibl. Græca.*) Some fragments of Philippides have been collected by Hertelius and Grotius.

PHILIPPINES, THE, constitute the most northern group of the islands that compose the extensive archipelago known under the name of the Indian Archipelago; and they lie between 5° and 20° N. lat. and between 120° and 127° E. long. The Strait of Balingtang, or Great Passage, separates them from the Batanes and Bashee Islands, which lie farther north. On the east extends the Pacific, and on the south the Celebes Sea. Two rows of small rocky islands, which run from the southern coast of Magindanao, the most southern of the larger Philippine Islands, southward to the northern parts of Gilolo and Celebes, unite the Philippines with the Moluccas, and separate the Pacific from the Celebes Sea. Another row of rocky islands runs from the south-western extremity of Magindanao west-south-west to Capes Unsang and Labian in Borneo. They are called the Sulo Islands, and between their eastern extremity and Magindanao is the Strait of Basilan, which is frequently navigated by vessels sailing to China. Farther north, the Philippines are connected with Borneo by another chain of islands, which extends in a north-north-east and south-south-west direction between the island of Mindoro, one of the Philippines, and the Capes of Inaruntang and Sampanmangio in Borneo. This chain, which is called the Palawan Islands, or the Archipelago of Felicia, separates the Mindoro Sea from the Chinese Sea, which are connected by Mindoro Strait. The Mindoro Sea and the Chinese Sea wash the western shores of this group.

The Philippines consist of ten larger and a great number of smaller islands. The larger islands have altogether an area of more than 120,000 square miles, according to the estimate of Berghaus, in which the surface of Magindanao, whose coasts are very imperfectly known, is estimated at 36,140 square miles. The smaller islands comprehend, according to the same authority, 6230 square miles; and the whole group more than 127,000 square miles, which is about 15,000 square miles more than the surface of the British Islands. Nine of the larger islands are considered as subject to the Spaniards, who have also some settlements on the northern and south-western coast of Magindanao, the remainder of this island being in possession of the sultan of Magindanao and some native tribes. We shall notice the larger islands separately.

1. *Luzon,* which is by far the largest of these islands, has according to Berghaus, an area of 57,405 square miles, which approaches very nearly the area of England and Wales

The name means a *mortar*. When the Spaniards, at their arrival, asked for the name of the island, the natives, who had mortars before their doors, called *losong*, and which are used in cleaning rice, thought they were asking for the name of these utensils, and answered accordingly: thus the island, whose proper name seems to be Ybalon, received the name of Luzon. The form of the island, which is extremely irregular, may be compared to a bent arm. Its length, along a straight line drawn from the most southern point, Punta Calaan, to Punta Cabicunga, hardly exceeds 420 miles, but measured along the bend it is more than 550 miles. The width varies between 10 and 136 miles. Where the bend occurs, which is near 14° N. lat., a deep bay enters the land from the north, and divides the island into two peninsulas. The isthmus which connects the two peninsulas is only from 10 to 12 miles wide, and nearly 50 miles long. The western and smaller peninsula is distinguished by the name of Camarines. Besides the bay, which lies to the east of the isthmus, and is called Seno de Lamon, the rocky coast of the island is indented by a great number of larger and smaller bays, among which the most extensive on the larger peninsula are the Bahia de Manila and the Golfo de Lingayen, both on the western side; and on the peninsula of Camarines, the Bahia de S. Miguel and the Seno de Albay on the northern coast, and the Seno de Ragay on the southern.

That portion of the island which lies north of 16° N. lat. seems to consist of one extensive mass of rocky mountains, which in many places come close to the shore of the sea, and in others are divided from it only by a narrow strip of low and frequently sandy ground. This mountain-mass terminates on the eastern shores of the island in very steep and high rocks, which render nearly the whole of this coast inaccessible. Accordingly we find that, except at one place, where there is a bay of moderate extent, there is no settlement of the natives of Malay origin, and the mountains, which rise to a great elevation, are only inhabited by the wandering Haraforas. This mountain-region, which extends from Cabo S. Ildefonso, on the south, to Punta S. Vincente on the north, a distance of nearly 200 miles, with an average width of 30 miles, is known under the name of Montes Caravallos. Along its western declivity there is a valley which is traversed in its whole length by a river called Cagayan or Tagayo. Between 14° and 15° N. lat. this valley enlarges to a plain of considerable extent, called Llanada del Difun, on which there are several Malay settlements, as well as in the valley itself, which extends to the northern coast of the island, and seems to be in general of moderate width. These are the only settlements in the interior of the northern districts of Luzon which are subject to the Spaniards, and they do not appear to be numerous or large. We are not informed whether the river Cagayan is navigable. West of the vale of the Cagayan there is another mountain-region, which is also 200 miles long, and probably above 60 miles in width. It is called Sierra Madre, and appears to rise even higher than the Montes Caravallos; the western declivity however is not steep, but has a gentle slope, which in some parts sends out low rocky ridges to the beach, but generally terminates at some distance from it, leaving between its base and the sea a wide tract of comparatively level and fertile ground. On this tract, and on the banks of some rivers which furrow the mountain-slope, the settlements are numerous. The Sierra Madre only extends to the northern coast of the island in one place, where a high rocky mass, called also Montes Caravallos, reaches the very beach. The low country which separates the sea from the steep declivity of the Sierra Madre along the northern coast is sandy, and generally sterile; the settlements in this part are consequently small and few in number. The elevation of the mountains has not been determined, but it is observed that they do not attain the snow-line, and probably they do not rise above the line of trees.

The Montes Caravallos, or eastern mountain-mass, do not terminate at Cabo de S. Ildefonso, but continue southward to Puerto Lapan (15° N. lat.), and so far they seem to preserve their high and rugged character, though the width is diminished to about 10 miles. But as they proceed farther south between the sea and the lake, called Laguna de Bay, they diminish in height as well as in width. Their general elevation in this part, according to an estimate of Meyen, does not exceed 4000 feet above the sea-level, though a few summits may rise 2000 or 3000 feet higher. In this part of the range both declivities are gentle, and admit agricultural settlements, which however are more numerous towards the lake than towards the sea. The Montes Caravallos continue farther south, and turning to the south-east they apparently run in an unbroken line through the isthmus which joins the peninsula of Camarines to the main-body of Luzon, and they terminate at the south-eastern extremity of the isthmus in the projecting promontory called Cabesa Bondoc.

The Montes Caravallos are not united by a mountain-ridge with the Sierra Madre; but south of 16° N. lat., near the southern extremity of the last-mentioned mountain-mass, a broken and elevated tract extends between them, which constitutes the uniting link between the two mountain-masses; along the south-western base of this tract and the western of the Montes Caravallos, there is a level plain of great extent and fertility, called the Plain of Pampanga. This plain extends from the innermost recess of the Gulf of Lingayen (16° N. lat.) on the north, to the Bahia de Manila (14° 45′) on the south. It is about 90 miles in length, with an average width of about 30 miles, so that it covers a surface of 2700 square miles. A few isolated hills rise on this plain, among which one attains a considerable elevation: it is called Mount Aragat, and is remarkable for the great number of hot springs which issue from its base, and the deep ravines by which its sides are furrowed. The whole plain is very little elevated above the sea-level, full of lakes, and traversed by rivers, whose course is nearly imperceptible except in the rainy season. In the northern districts there is a large lake, the Laguna de Canarim, on the most elevated part of the plain; two rivers issue from it, one towards the north, which falls into the Gulf of Lingayen, and the other towards the south, which enters the Bahia de Manila. These rivers, of which the first is called Rio Grande, and the second Rio de Pampanga, are of great importance, as the produce of this rich and well cultivated tract, which is mostly covered with plantations of sugar, can be brought by water to Manila during the rainy months. The population of this plain probably does not fall short of half a million.

The Plain of Pampanga does not extend on the west to the shores of the Chinese Sea, being separated from it by another mountain-region, the Montes Zambales, which extend from the promontory of Bataan, on the west of the Bahia de Manila, northward to Cape Bolinao, which constitutes the western side of the Gulf of Lingayen. This mountain-region is about 100 miles long and 20 miles wide. The highest portion of it is towards the south, where its general elevation is estimated to exceed 7000 feet. North of 15° N. lat. however the mountains grow lower, and where they approach Cape Bolinao they are of moderate elevation. Five summits in this mountain-mass rise to a greater elevation, but the height of none of them has been determined. These mountains approach very near the sea, and agricultural settlements have been formed only in a few places. The mountains themselves are wooded, and in possession of the Aetas, or original inhabitants of the island. It is not said that any active volcanoes exist in any of the mountain-regions in the northern districts of Luzon, except that a mountain, probably that which on our maps is called St. Thomas, and which lies on the western side of the Gulf of Lingayen, in 16° 12′ N. lat., made an eruption in 1641.

The Bahia de Manila, is one of the finest basins in the world. It is nearly of a circular form, and measures from 20 to 25 miles in every direction. It is nearly free from shoals, and contains excellent anchorage. The surface is rarely agitated by winds. It is entered by two channels: the northern, called Boca Chica (little mouth), is more than 2 miles wide between the large island of Corredigor and the peninsula of Bataan; the southern, between the small island of Pulo Cavallo and the Isla Sinalan, near the southern coast, is nearly 6 miles wide, and called Boca Grande. The bay is usually entered by the Boca Chica, except when the wind blows from the east, which always produces a strong current running westward through this channel, and the Boca Grande is then preferred. The tides in this bay are very irregular during the north-east monsoon, when the low tides run through the Boca Chica with rather a strong current for 18 hours, whilst the high tides last only six, and are sometimes feeble, sometimes strong. The rise is about three feet at full and change. There is an excellent harbour before the Boca Chica called Puerto de Mariveles.

The shores surrounding the bay are low, except at the entrance, where there are rocky mountains of considerable elevation. Along the northern shores the low Plain of Pampanga extends for nearly 20 miles, and is here divided into a great number of islands by the numerous branches into which the Rio de Pampanga divides as it approaches the bay. A hilly country begins west of the bay and a mile or two from the shores, and extends eastward to the Laguna de Bahia. This lake is about 20 miles long, and on an average 10 miles wide, but is divided into two nearly equal parts by a projecting tongue of land and an island situated opposite its termination. The western part of it is in general only from 5 to 6 feet deep, but the eastern part is much deeper, and in the centre it is from 17 to 20 feet deep. It is surrounded by low land, which at a short distance rises into hills. The surface of the water is about 36 or 40 feet above the sea-level of the bay. The water of the lake is carried off by five very narrow channels, which soon unite, and, being joined by a small river, constitute a wide and tolerably deep stream, called the Rio Pasig, which flows westward to the Bahia de Manila, and has its outlet between the two towns of which the capital consists. The slightly hilly country that surrounds the lake and extends on both sides of the Rio Pasig is very fertile and populous.

From the banks of the river and of the lake the country rises gradually to the south for 10 or 12 miles, when it is followed by a tract of land the surface of which is extremely uneven, and has a number of isolated mountain-summits scattered over it, many of which rise to a considerable height. Nearly in the middle of this region is the Laguna de Taal, a lake of a circular form, about 12 miles in length from north to south, and 10 miles in width where it is broadest. This lake contains the island of Taal, and the volcano of the same name, which made a great eruption in 1754: in 1825 smoke issued from it. At a considerable distance east of the lake is another volcano, called the Banajan de Tayabas. The country which extends southward from these volcanoes appears to be of great fertility, and is pretty well settled: it terminates on the south at the Estrecho de Mindoro, or the Little Strait of Mindoro, so called to distinguish it from the Large Strait of Mindoro, which lies farther west and separates the island of Mindoro from the islands of Calamianes. The Little Strait of Mindoro is nearly 50 miles long and about 5 miles wide in the narrowest part. It is navigated by vessels, which when coming from the Pacific sail round the south-eastern extremity of Luzon through the Embocadero de S. Bernardino. On the northern shores of the Little Strait of Mindoro are two good harbours, called respectively Ensenada de Batangas and Ensenada de Balayan.

The peninsula of Camarines, or the south-eastern part of the island of Luzon, is not connected with the north-western part by a range of mountains. Towards the eastern extremity of the isthmus, which connects both parts, the mountains entirely disappear, and where the two bays called Seno de Lamon and Seno de Ragay approach nearest to one another, and are only about 15 miles apart, the intervening country is low, and constitutes a valley several miles wide, which runs across the island from one bay to the other. It is not improbable that a natural water-communication exists between the two bays, like that in the Plain of Pampanga.

The peninsula of Camarines is chiefly occupied by a mass of high mountains, which come close to the southern shores, and only in a few places leave a narrow strip of level ground. But the northern declivity of this range is not so steep, and terminates about 6 or 8 miles from the sea. The intervening tract is at some places covered with rocky hills, and in others it extends in low plains. On this tract, and at a short distance from the mountain-range, there are ten volcanoes, the names of which, from north-west to south-east, are Bonotan, Bacacay, Lobo, Colasi, Ysarog, Yriga, Bugi, Masaraga, Albay, or Mahon, and Bulusan. The Volcano de Ysarog, which occupies the centre of the isthmus between the Bahia de S. Miguel and the Seno de Lagonoy is distinguished by its size and elevation; that of Albay or Mahon is noted for the frequency of its eruptions. No eruptions of the other volcanoes are recorded. There is a considerable number of agricultural settlements on this volcanic tract, especially in the country surrounding the Bahia de S. Miguel. This bay is about 25 miles long from north to south, with an average width of 12 miles. On the south it is enclosed by a low and fertile tract, but near its entrance the country rises into high hills. Being enclosed by high ground, and having excellent anchorage, it forms a very good and safe harbour. A shoal in the middle of the entrance has only four feet water on it, but the channels on each side of the shoal are deep and free from rocks. The strait which divides the most south-eastern extremity of Luzon from the island of Samar, is called the Embocadero de S. Bernardino, and is dreaded by navigators on account of its currents and eddies.

2. *Mindoro*, which is separated from the island of Luzon by the Little Strait of Mindoro, and from the islands of Calamianes by the Great Strait of Mindoro, is 100 miles long, and rather more than 40 miles wide on an average. Its area, according to Berghaus, is 4115 miles. The mountains which occupy the interior rise to a very great elevation; but they descend in gentle slopes, and the sea-shore is skirted by low hills, which are covered with forests of lofty trees. There is only a small number of Malay families settled on some points of the coast. In 1818 their number did not exceed 951, and the whole population amounted only to 4680 individuals. It is the least important island of the whole group, though it has several good harbours on the Great Strait of Mindoro, among which the Ensenada of Manguirin, towards the north, and the Ensenada of Palavan, towards the north, are the most extensive; but the approach is dangerous, owing to reefs.

3. *Panay* has the form of an isosceles triangle, the base of which is more than 100 miles long, and the other sides more than 80 miles. The area, according to Berghaus, is 4579 square miles, or nearly double that of Devonshire. Along the western coast the country is of moderate elevation, well cultivated, and populous; villages are numerous; and the churches, though small, are well built. At some distance from the shore, a mountain-ridge runs from Punta Potol, on the north, to Punta Nasog, or Naso, on the south, and appears to be very steep. We have no account of the natural features of the countries contiguous to the northern and south-eastern coast. According to the census of 1818, the population of this island was 292,750; and according to an estimate in 1837, it had increased to 406,030 individuals. This shows that Panay is the most important island of the whole group next to Luzon, and is even more densely peopled than that island.

•4. *Negros* is about 140 miles long, with an average width of about 25 miles. The surface, according to Berghaus, is 3827 square miles, or 1000 miles more than the county of Lincoln. We are not acquainted with its surface and soil. It seems to be very mountainous, and contains a comparatively small number of agricultural settlements. The population subject to the Spanish government in 1818 consisted of 35,445; and in 1837, of 35,622 individuals.

5. *Zebú*, or *Cebú*, extends in length from south to north rather more than 100 miles, but it is hardly more than 20 miles wide on an average. The area, according to Berghaus, is 2193 square miles, or about 150 square miles more than that of Norfolk. We are not acquainted with its natural features and the quality of the soil, but we may presume that it does not contain much waste land and high mountains, as the population is very considerable. In 1818 it amounted on the island to 68,772 inhabitants; and in the whole province, which included the island of Bohol and four smaller islands, it amounted to 168,426 individuals. According to the returns of 1837, the population of the whole province had increased to 250,817 individuals.

6. *Bohol*, situated between Zebú on the west and Leyte on the east, is the smallest of the larger Philippines except Masbate. It extends in length from west to east about 45 miles, with an average width of 30 miles. Berghaus determines the area to be 1354 square miles. We have no account of its natural capabilities, but they must be great, as it contained in 1818 a population of 80,344 individuals, or nearly 60 persons to a square mile. According to the account of 1837, in which the island is included in the government of the province of Zebú, we must suppose that it has greatly increased since the census was taken.

7. *Leyte*, or *Leite*, extends from south to north about 120 miles, with an average width of 35 miles. According to Berghaus, the area is 4257 square miles. We are no better acquainted with this island than with those to the west of it. The population of the province of Leyte, to which two smaller islands of inconsiderable extent belong, amounted, in 1818, to 40,623; but in 1837, to 92,165.

8. *Samar*, or, as it is also called by the natives, *Ybabas*, is the largest of the Philippines which are subject to• Spain, next to Luzon. It has the form of a triangle whose apex is turned to the south: the base measures about 60

miles, and the perpendicular length about 115 miles. The surface is 5547 square miles, or about 300 square miles less than Yorkshire. A great part of this island, especially towards the north, is covered with high mountains, which are visible from a great distance at sea. The soil in general, though not distinguished by fertility, is far from being sterile. According to the census of 1818, the population of Samar and the small island of Capul amounted to 57,922 individuals, a number which had increased in 1837 to 99,635.

9. *Masbate* is in the middle of that sea-basin which is surrounded by the islands described from No. 2 to No. 8, and by the peninsula of Camarines, and is called the Bisaya Sea: the islands surrounding this basin and those within it are comprehended under the general name of the Bisaya Islands. Masbate has a triangular form, whose apex is to the east. The base, or western coast, is nearly 40 miles long, and the perpendicular length about 55 miles. Berghaus makes the surface 1225 square miles. This island appears to be a mass of high rocks, and to contain very little cultivable ground. The population is very small. In 1818 it did not contain more than 2310 persons.

Between the most northern point of Masbate and the promontory of Cabesa Bondoc is the island of Burias, which has an area of only 327 square miles. It does not acknowledge the authority of the Spaniards. When Forest was on Magindanao, he was informed that the Illanos from that island had formed a settlement on Burias, and that the Spaniards had been unable to expel them.

10. The island of *Magindanao*, or *Magindano*, is the most southern of the Philippines, and the largest next to Luzon. Its form is extremely irregular. Berghaus makes the area 36,140 square miles, or about 14,000 square miles less than that of England without Wales. The coast-line perhaps considerably exceeds 1000 miles. Our information respecting this island is very scanty, and we are indebted for the little that we know to Forest, who visited the island in 1775, and remained there nearly eight months. From the information that he collected during his stay, we learn that where the meridian of 124° E. cuts the island, two bays penetrate into it, the Bay of Illano from the south, and that of Siddum, or Panguyl, from the north, and that their innermost recesses are only two days' journey from each other. Near the isthmus which is thus formed is a large lake called Lano, which is from 15 to 20 miles wide from south to north, and has a greater extent from east to west. The country enclosing the western portion of the lake is hilly, but on the east of it extends a large, fertile, well-cultivated, and populous plain, inhabited by a tribe of the Malay race, called Illanos. The population of the country enclosing the lake was stated to be 61,300. Along the southern shores the country, as far as Forest had an opportunity of seeing it, was in most parts hilly, but not mountainous: in some places there were extensive plains, and most of the valleys were wide and fertile. It seems however that the country which lies along the eastern shores of the island contains ranges of lofty mountains, which are inhabited by the Haraforas, or original inhabitants of the island. The country west of the isthmus, between the bays of Illano and of Siddum, probably contains mountains only in the northern districts, and is entirely inhabited by Malays. Numerous rivers water this large island; but we are only acquainted with the Pelangy, which flows from east to west, rising near 125° 30′ E. long., and falling into the Bay of Bongo opposite the island of Bunwert. Though its course probably does not exceed 100 miles, it is navigable for large river-boats to a great distance from the mouth, and drains a wide and fertile valley, which enlarges near the sea into an extensive plain, where the river divides into several arms, and forms a very fertile delta. Forest observes that large tracts of this island are destitute of trees and covered with fine grass, and that such savannahs do not occur in any other island of the Indian Archipelago. There are volcanoes on Magindanao: the existence of three is certain. One of them, the Sanguili, is not far from the southern extremity, 5° 44′ N. lat. and 125° 18′ E. long. There is another northwest of Cape S. Augustin, the south-eastern point of the island; and a third on the eastern side of the Bay of Illano. Between the northern coast of Magindanao and the island of Zebú, is the island of Siquijor, or Fuego, on which also there is an active volcano.

Magindanao is politically divided into three parts. The Spaniards have formed a great number of settlements on the eastern and western coast, where the inhabitants consist almost exclusively of Bisayes, or Malays of the Philippines. These settlements constitute two provinces of the general Capitanancy of the Philippines. The Spaniards have also a military establishment at Zamboanga, on the Strait of Basilan, at the south-western extremity of the island, in order to prevent the pirates from the Sulo Islands from extending their predatory visits to the Mindoro Sea. But these islands are exposed to the depredations of the Illanos, who not only possess the country about the lake of Lano, but also the greatest part of the shores of the Bay of Illano, and the western coast of the island between the Strait of Basilan and the wide and open bay of Sindangan. The large peninsula which extends between the Bay of Illano on the west and the Pacific on the east acknowledges the authority of the sultan of Magindanao, whose subjects are mostly Malays, and inhabit the country along the coast; but the interior is occupied by the Haraforas, who are treated by the Malays not as subjects, but as slaves.

Climate.—We do not possess a regular series of meteorological observations for any of the Philippines, except those made by Le Gentil at Manila more than sixty years ago, and they are of little value. Meyen, who was there in September and October, found that in this season of the year the thermometer never exceeded 83° at noon, and generally remained below 80°, and that the difference between day and night rarely amounted to 6 degrees. Comparing his observations with those of Le Gentil, he thinks that the mean temperature of the summer may be fixed between 80° and 82°, and that of the winter between 70° and 72°, and that the mean temperature of the whole year probably would fall somewhat short of 77°. The year is divided between the dry and rainy seasons, which depend on the monsoons. The rainy season occurs in the south-west monsoon, during which an immense quantity of water comes down, the rains sometimes continuing for ten or even fourteen days without intermission. The rains commence in the beginning of May, and do not cease before the end of October or the beginning of November. They attain their maximum in the month of July. Between the beginning of November and the end of April showers sometimes occur. The northern part of Luzon is situated within the range of those terrific hurricanes which are called *tifun*, and which are rarely felt south of 14° N. lat. These winds occur between the beginning of May and the end of December, but are less violent towards the end of the year. In June and July they rage with incredible fury; but they generally blow only four or six hours, and frequently for a shorter time. They begin to blow from the east, in a contrary direction to the then prevailing south-west monsoon, and turn gradually to the south and south-west, when their force begins to fail. The damage which is caused by them is as great as that produced by the hurricanes of the West Indies. Earthquakes occur frequently, and sometimes cause great damage.

Productions.—The staple articles for the European market are sugar, indigo, rum, and tobacco; and for the Chinese market, sapan-wood, rice, edible birds' nests, and trepang. The sugar-cane is most extensively cultivated in the Plain of Pampanga; and though the manner of preparing the sugar is not a good one, the sugar itself is much prized, and sent to many parts of Europe. Indigo is cultivated to a great extent, and some has been exported, which was not considered inferior to that of Guatemala; but in general the manufacture of this article is not conducted with sufficient attention. Tobacco, which grows very well in many places, and is of the first quality, is only exported in the form of cigars. Rice, for which there is always a ready market, and which constitutes the principal food of the bulk of the population, is the first object of cultivation nearly all over the island. Where the fields cannot be put under water, the upland rice is cultivated. Sapan-wood (Caesalpinia sapan) abounds in some of the mountainous districts, in the forests, and finds a ready sale in China. The quantity of edible birds' nests and trepang which is sent to China is not great. A small quantity of coffee, ebony, sulphur, cotton, pearls, mother-of-pearl shells, tortoise-shells, and cordage, are also exported. The coffee-plant was introduced about fifty years ago, and is now found wild in many of the woods surrounding the Laguna de Bay, having been propagated by a species of civet cat which swallows the berries. The greater part of the coffee exported from Manila is gathered from these wild plants, and is equal or superior in flavour to that of Bourbon. Cotton cannot become an important article of exportation until some method is adopted, less expensive than that now in use, of separating it from the seed. Cordage is made from the fibres of a species of banana. The exterior fibres of its stem, which grows to the height of seven or eight feet, are coarse, like hemp; but the inner fibres are finer; and those near the centre are finer than the best flax, and are used in the island in the manufacture of several stuffs for clothing. The hemp itself has also of late supplied an article of exportation. Cacao, which has been brought from Guatemala, is cultivated in many places in Luzon, and has even spread to the most southern islands. Forest found a cacao-tree in Magindanao. The consumption of chocolate being great, cacao is not exported, though it is said to be equal to the best grown in America. Cinnamon is said to grow wild in many of the islands, and the clove-tree is found on Magindanao. The sago-palm is also indigenous, but the cultivation is little attended to.

The principal food of the inhabitants consists of rice and fish. They also cultivate millet and several kinds of beans and other pulse. The fruit-trees which succeed best, besides the cocoa-nut, the cultivation of which is carefully attended to, are the bread-fruit, mango, and two kinds of oranges and figs. The plantations of plantains are extensive, and also those of areca-nuts. The bamboo and prickly calamus are cultivated, and both of them supply materials for the construction of the habitations of the natives.

The buffalo is universally used in all field-labour, though in some parts people have begun to substitute the bullock for it. The buffalo here, as on all the islands of the Indian Archipelago, is of uncommon size and strength; the caymans, which are in the Laguna de Bay, and rather of a large kind, never attack a buffalo. Cattle have been introduced by the Spaniards, and are abundant in some parts of the plains, which are destitute of woods, like the prairies of North America. Horses have also been introduced by the Spaniards; the breed is small, but very hardy; they are only used for riding. Sheep are few, but goats are more numerous. Pigs are plentiful, except on Magindanao, where the inhabitants are Mohammedans. Domestic fowl are reared in immense numbers, especially ducks on the banks of the Laguna de Bay. Except the caymans, which are numerous in the Laguna de Bay, there are no rapacious animals. The woods swarm with deer and wild hogs. The Philippines are rather distinguished by the number than by the variety of wild fowl. The sea abounds with fish, and the inhabitants, like all the tribes of the Malays, prefer fish to meat. The number of families which gain their subsistence by fishing is very great. Among the fish found in the Laguna de Bay is a saw-fish of large size, which attacks the cayman. Besides pearls and great quantities of mother-of-pearl shells, cowries are very plentiful about some of the smaller islands and rocks. Wild bees are very numerous in the woods, and wax and honey are important objects of internal commerce. The islands rarely suffer from drought, and are periodically (perhaps once in ten or fifteen years) devastated by locusts.

Gold, iron, and copper are said to exist in Luzon and Magindanao, but at present none of these metals are worked. It is said that gold is tolerably abundant on the mountains along the northern shores of Magindanao. Salt is made in several places, and brimstone is collected on some of the mountains of Luzon.

Inhabitants.—When the Spaniards took possession of the Philippines, they found the islands occupied by two different races of men. In the plains and hilly tracts several tribes of Malays had settled, who spoke different dialects of the same language, and were subject to a great number of petty sovereigns. The mountains were occupied by a black race, which belongs to the race of Austral negroes, and was called by the Spaniards, Negritos or Aetas, while the Malays were called Indios. The Negritos were probably the aborigines of the islands, and had retired to the mountains when the Malays began to occupy the lower country, being of a diminutive size, and unable to offer resistance: in the mountains they had maintained their independence. The Malays have submitted to the sway of the Spaniards, but the Negritos are independent in the mountain fastnesses: they run away at the sight of foreigners, and avoid all communication with them. It is however stated by Forest that many of the Negritos have been converted to Christianity on the island of Magindanao, where the Malays treat them as slaves, and take from their huts what they like. The Negritos of Magindanao consequently often change their abodes, and retire to those parts which are subject to the Spaniards, where they embrace Christianity in preference to Islamism, because they are permitted to eat pork, of which they are very fond. In Magindanao the Negritos are agriculturists, and the Malays who reside along the coast receive from them a considerable part of the agricultural produce necessary for their consumption, giving in return several utensils and baubles, which are brought from other countries. The Negritos in Luzon are savages, who have no fixed abode, but rove about the mountains, and live by the chase, and on wild fruits and honey. They occupy the greatest part of the Montes Caravallos, and also the higher part of the Montes Zambales. The Malays are divided into a great number of tribes, of which that called Tagala occupies the neighbourhood of Manila and the country round the Laguna de Bay. The other tribes that are numerous, the Pampanga, Zambales, Pangasinan, Ylocos, and Cagayan, inhabit the other plains and lower country. They are all subject to the Spaniards. Some of the tribes in the Sierra Madre have not embraced Christianity, and are not regularly subject to the Spanish government. One of them, the Ygorrotes, who inhabit the mountains east of the Gulf of Lingayen, are distinguished by a peculiar physiognomy and a lighter colour, which, it is supposed, must be attributed to a mixture with Chinese. As to the political condition of the Malays, it is unanimously stated that they are proprietors of the soil and free subjects, and treated by the Spaniards as such. The forts, which are built in many places along the coast to oppose the pirates, are in their power, and are garrisoned by them. It must be a matter of surprise that, under such circumstances, the Spaniards, whose number is very small (in 1818 it did not exceed 3000), are not driven out by the Malays; but this is explained by the fact of the great authority which the clergy exercise over them, and by which they are kept quiet, so that they never rise against government except when excited by the clergy, which has been the case several times. Though such a subjection to the clergy would lead us to suppose that the people must be in a low condition, this supposition is contradicted by travellers. Meyen found them well lodged, clothed, and abundantly provided with food. They seem not to be inferior to the peasantry of most countries of Europe. Besides the Spaniards, there are a few people of colour, who, in 1818, amounted to 6170 souls: there are also some Chinese, who, in 1818, were not more than 6201, of which number 1569 were Christians.

Political Divisions and Population.—The Philippines, as far as they are subject to Spain, are divided into twenty-nine provinces, of which seventeen are situated in the island of Luzon, and twelve in the smaller islands, and on the northern and eastern coast of Magindanao. The population, in 1818, amounted, according to the census, to 2,214,142 individuals; and in 1837, according to an estimate founded on the number of families paying the capitation tax, to 3,202,760. The following tables exhibit the particulars:—

1. *Population of the Provinces on the Island of Luzon, or Nueva Castilla.*

Names of Provinces.	1818.	1837.
1. Tondo	149,095	230,025
2. Bulacan	125,021	181,970
3. Pampanga	106,381	181,720
4. Pangasinan	119,322	229,402
5. Ylocos del Norte	135,748	172,207
6. Ylocos del Sur	147,095	236,510
7. Cagayan	61,322	92,222
8. Zambales	18,841	36,080
9. Bataan	23,393	36,087
10 Nueva Ecija	15,506	44,570
11. Tayabas	48,676	85,245
12. Camarines del Sur	113,892	158,972
13. Camarines del Norte		24,985
14. Albay	92,665	131,745
15. Laguna de Bay	86,689	142,805
16. Batangas	112,120	188,660
17. Cavite	51,665	91,602
	1,407,431	2,264,807

The difference between the population of 1818 and 1837 may partly be explained by the great increase of cultivation in consequence of the increased demand for the produce of the country, which was caused by opening the port of

Manila to the commerce of all foreign nations. It may also be partly accounted for by the circumstance that in the census of 1837 the tribes which are either independent or not quite subject to the Spaniards were comprehended, while in 1818 they were omitted; and their number was estimated at the last-mentioned period at the following rate:—

	Individuals.
564 families newly converted and still under the sway of the monks, composed of	2,820
788 families of friendly Ygorrotes in the province of Pangasinan, containing	3,940
2160 families of Tinguianos in the provinces of Ylocos	10,800
1180 families of unconverted Ygorrotes in the same provinces	5,900
1523 families of non-converted Negritos in the same provinces	7,615
	31,075

If these are added, the population of the island of Luzon consisted, in 1818, of 1,438,506 individuals.

2. *Population of the Islas Bisayas.*

Names of Provinces.	1818.	1837.
18. Mindoro, comprehending the islands of Mindoro . . 4670 souls Marinduque . 9777 Islas de Luban . 4349	18,796	29,632
19. Antique, or the western coast of the island of Panay	50,597	55,100
20. Iloilo, or south-eastern part of the island of Panay	176,901	230,410
21. Capiz, or northern part of Panay, including the islands— Romblon and Sibuyan 3840 Banton, Tablas, Simara, and Maestro de Campo 2824	65,262	120,520
22. Leyte, comprehending the island of the same name, and the islands of Panamao . . . 1065 Panaon . . . 3766	40,623	92,165
23. Zebu, comprehending Zebu, and the islands— Bantayan . . 5,235 Siquijor . . 5,748 Bohol . . . 80,344 Davis . . . 4,981 Panglao . . 3,346	160,099	250,817
The Islas Camotas are comprehended in a parish of Zebu.		
24. Samar or Ybabao, consisting of the island of that name and the island of Capul, with 3013 inhabitants	57,922	99,635
25. Calamianes, comprehending a group of islands called Islas de Calamianes, which properly do not belong to the Philippines, but to the Archipelago de Felicia or Palawan, and the northern portion of Palawan, called Paragua. The Islas de Calamianes contain . . 2,060 inhabitants and Paragua . 11,097	13,157	16,052
26. Islas Batanas, which are situated north of the Strait of Balingtang, or the Great Passage, by which they are divided from Luzon	10,576	8,000
27. Negrós, embracing the island of Negros	35,445	35,622
	619,378	937,953

3. *Population of the Spanish portion of Magindanao.*

Names of the Provinces.	1818.	1837.
28. Caraga, comprehending the eastern coast of the island	15,957	29,977
29. Misamis, embracing the northern coast east of the Bay of Sindangan	26,226	34,583
To these two provinces is to be added the Presidio, or military establishment at Zamboanga	8,640	10,000
	50,823	74,560

According to the census of 1818, the whole population was 2,108,707, to which however it was thought necessary to add 5 per cent. on account of some small errors, which gave the whole amount of the population 2,214,142.

The rapid increase of the population in the period between 1792 and 1837 may be inferred from the number of families paying capitation tax, which in

1792	amounted to 280,093	1815	amounted to 385,568
1805	„ 347,841	1817	„ 412,679
1812	„ 382,568	1818	„ 436,047

and in 1837 they amounted to 654,670.

Towns.—It may be presumed that in so populous a country there must be a considerable number of towns, but as travellers do not extend their excursions to any great distance from the capital, Manila, we are not acquainted with them. In the census a considerable number of towns are mentioned with a population exceeding 5000 souls, and in 34 places it is stated to exceed 10,000 individuals. Six places of the last description are noted in the province of Iloilo, in the island of Panay.

Manila, the capital and seat of the captain-general or governor of the island, is built on the eastern shores of the Bahia de Manila, at the mouth of the river Pasig, or the channel by which the Laguna de Bay discharges its water It consists of two towns with extensive suburbs. The city, Manila, is built on the southern banks of the Pasig, and enclosed by high walls, and a ditch which is connected with the river. The streets are straight, wide, and well paved. The houses are built of stone, and are substantial. There are several well-built churches and convents. The palace of the captain-general is not distinguished by its architecture, but the custom-house, or *aduana*, is a large and fine building. The city is only inhabited by Spanish families, and in 1818 did not contain above 6875 inhabitants, including the Malay servants of the Spaniards. Close to it on the south are the suburbs of Hermita and Malate, which in 1818 contained 10,550 inhabitants. A well-built bridge leads from the city over the Pasig to Bidondo, a large place, which however only contains habitations built in the fashion of the Tagala, though it is the commercial town. In 1818 Bidondo contained 21,386 inhabitants. Contiguous to it on the beach is Tondo, the capital of the province of the same name, whose population in 1818 amounted to 14,610 inhabitants. At the back of Bidondo are eight suburbs, the population of which in 1818 amounted to 23,462. The population of all these places together amounted in 1818 to 76,883 individuals. It has been asserted that the population was not less than 150,000, which is probably an exaggeration; but when the increase of the population of the province of Tondo is considered, we may reasonably suppose that Manila at present can hardly contain less than 120,000 inhabitants. The houses in all these places are built of bamboos, and are elevated from 6 to 8 feet above the ground, resting on thick pieces of bamboo. The number of Chinese is considerable, and is said to amount to 30,000, which however seems to be an exaggeration. In the large square of the city, which is more than 100 yards wide, stands the statue of Charles IV. of Spain, of bronze, somewhat larger than life. Ferdinand VII. gave it to the town of Manila in 1824. It is considered a good work, but is too small for the square. Manila contains a royal college for the instruction of youth, a university which was founded by Philip IV. in 1645, a nautical academy, an hospital for the poor, and various other religious and charitable establishments.

Cavite, which lies south of Manila, is a well built fortress, situated at the extremity of a tongue of land about two miles long: it protects the Ensenada de la Estanzuela, the only harbour in the Bahia de Manila. The arsenal is in that fortress, and vessels are built there. The fortress contained in 1818 only 1926 inhabitants, but the adjacent town of S. Roque contained a population of 9926.

Manufactures.—The Malays use very few manufactured goods exported from other countries, and they have applied themselves to some branches of manufacture with success. They make very good earthenware, which however is not exported, being much inferior to that of China. But the cotton stuffs, which are made in some parts, are, or were formerly, exported to Mexico. Another branch of industry in which they excel is the plaiting of straw and slips of wood. Hats made of the latter material are highly prized and exported. A single hat of the first quality fetches in Manila from 17 to 18 Spanish dollars, or 4*l*. Mats and similar objects are also exported. At Manila there is a royal manufacture of cigars, in which 450 persons are constantly employed.

Commerce.—The commerce of the Philippines was formerly limited to the mother-country and the Spanish colonies in America. The most important and lucrative branch was the commerce with Mexico, which was conducted by means of gallions that sailed once a year between Acapulco and Manila. They chiefly carried to America silk manufactures and other goods obtained from the Chinese, and brought in return the produce of the Mexican silver-mines. This commerce had little effect on the increase of population and the improvement of cultivation. At that time no foreign vessels, except from China, were admitted into the ports of the Philippines, and the islands accordingly advanced very slowly. But since the Spanish colonies in America have obtained their independence, the port of Manila has been thrown open to all commercial nations, and the increase of the exports has been very rapid, as appears from the following table, which shows the quantity of the principal articles exported in 1818, 1829, and 1830:—

	1818.	1829.	1830.	
Sugar	14,405	120,274	138,387	picols.
Indigo	3,400	11,809	13,863	picols.
Sapan-wood	18,825	11,675	11,594	picols.
Rice .	. .	114,793	197,486	cavan.
Cigars .	. .	4,595	4,257	arrobas.

1 picol = 140 lbs. 1 arroba = 25 lbs.

Manila carries on trade with Canton, Amoy, and Shanghae, in China; Awatska in Kamtchatka; Acapulco and other ports of Mexico; with four of the ports of the United States of North America; with London, Gibraltar, three ports of France, with Hamburg, the Mauritius, British Hindustan, Singapore, Batavia, Cochin-China, Borneo, and the Sulo Archipelago. The Chinese junks from Shang-hae do not visit any port farther west than Manila. In 1818 the number of foreign vessels that entered the port of Manila did not exceed 61; they were, Spanish 9, Portuguese 4, French 5, English 17, American 10, Chinese junks 13, and Borneo junks 3. The following table shows the number of vessels that entered the port and cleared out from it in 1828 and 1829:—

Names of the Nations to whom the vessels belonged.	Outwards.		Inwards.	
	1828.	1829.	1828.	1829
Spanish . .	38	43	31	41
American . .	—	20	29	33
English . .	—	22	13	14
Danish . .	—	—	5	—
Dutch . .	—	4	5	6
French . .	—	8	3	7
Portuguese . .	—	—	3	—
Hamburg . .	—	—	1	—
Prussian . .	—	1	4	1
Chinese . .	—	9	—	9
Other vessels, the name of the nation to whom they belong not stated	80	78	74	73
	118	186	164	184

This list is very far from being correct, as is evident from the circumstance that the nations to which nearly half the number of vessels belong, are not mentioned. But as it may serve to give some idea of the increase of the commerce of the town of Manila, we have given it as it appears in Meyen's 'Travels.'

The same author states that in 1828 the value of the goods exported amounted to 1,475,034 Spanish dollars (331,882*l.*), and that of bullion and specie to 62,486 Spanish dollars (14,059*l.*); in 1829 the goods to 1,397,623 Spanish dollars (314,465*l.*), and the bullion and specie to 62,275 dollars (12,012*l.*), and in 1830 the exported goods amounted to 1,497,621 (336,964*l.*), and the bullion and specie to 81,952 dollars (18,440*l.*). The value of the goods imported in 1828 amounted to 1,550,933 dollars (348,960*l.*), and that of bullion and specie to 401,827 dollars (90,411*l.*); in 1829 the former to 1,654,502 dollars (372,263*l.*), and the latter to 398,447 dollars (84,650*l.*). In 1830 the imported goods were to the value of 1,562,522 dollars (351,567*l.*), and the bullion and specie to the value of 178,063 dollars (40,064*l.*).

European vessels do not visit any other harbours of the Philippines except Manila, but it is very probable that the Bugis and inhabitants of Sulo, as well as the Chinese, who have a great number of junks in these seas, visit some of the smaller islands, especially the well-cultivated and populous island of Panay. The coasting trade of the Philippines is very active. It is carried on in small brigs, and in still smaller vessels, called galores, goletas, pontines, &c.; a great number of these vessels are employed in the coasting trade between Manila and the provinces of Ylocos and Pangasinan, and the islands of Panay and Zebu. In 1818 there cleared out from Manila 637 vessels of that description.

History.—The Philippines were discovered by Fernando Magalhaens in 1521, who was killed in one of the islands. [MAGALHAENS.] In 1564 a small squadron under the orders of Lopez de Legaspi was sent from Mexico to form an establishment, which he effected in the following year on the island of Zebu, the inhabitants of which submitted to the Spaniards without any resistance. In 1571 Legaspi founded the town of Manila; and as the Malays of this island were divided into a great number of communities independent of one another, and not accustomed to war, they also submitted to the foreigners almost without a struggle. Thus the Spaniards obtained the possession of this important group of islands almost without bloodshed, and they have preserved it by converting the inhabitants to Christianity, in which they have been perfectly successful, as the Islam at the time of the conquest had not extended farther than to the Moluccas. The Spaniards remained in undisturbed possession of the Philippines to 1762, when the English took the town of Manila. The inhabitants of Luzon however did not submit, but continued the war against the English under a Spanish officer, though with no great vigour. In 1764 the English restored Manila to the Spanish government. The Philippines, together with the Marianas, are administered by a governor who has extensive powers. The islands are divided into provinces, at the head of which is a governor, or alcalde mayor; and the provinces are subdivided into pueblos, which have also their petty governor, and officers subordinate to him.

(Martinez de Zuñiga's *Historical View of the Philippine Islands*; Kotzebue's *Voyage of Discovery into the South Sea, &c.*; Meyen's *Reise um die Erde*; Yldefonso de Aragon, *Estado de la Poblacion de Filipinas correspondente al anno de* 1818; Forest's *Voyage to New Guinea*; Moor's *Notices of the Indian Archipelago*; Berghaus's *Memoir von den Philippinen und Sulu Inseln*, and his *Map*; *Calendario de las Islas Filipinas*, for 1839, Manila.)

PHILIPPINES, NEW, more frequently called the Carolines, are a number of islands situated in the Pacific, between 138° and 164° E. long., and between 5° and 13° N. lat. In this wide tract of ocean there are several groups of small islands enclosed by reefs, and others are isolated. These islands are very imperfectly known, though the Spaniards, who obtained some knowledge of them from the natives who visited their settlement on the island of Guahan (Ladrones), claim the sovereignty of the New Philippines. They have however never made a settlement on any of these islands, though a Spaniard has occasionally paid them a visit, or a monk has gone for the purpose of converting the natives. Twelve years ago these islands were partly surveyed by the Russian navigator Lütke.

The islands, which lie either within the basins formed by the coral reefs, or contiguous to the reefs themselves on their interior side, are all small, and produce hardly anything except cocoa-nuts and bread-fruit. All the isolated islands are high, and some rise to a great elevation. The island of Feys rises on the shore to more than 1200 feet, but gradually slopes towards the centre, resembling in that respect most of the lower islands, which consist of a narrow strip of land of a circular form, enclosing a lagoon. The elevated islands have a great variety of trees and plants which afford food. The cultivated fields contain plantains and arums; from the root of the latter the inhabitants make flour. They also cultivate the sugar-cane, and have several fruit-trees besides the cocoa and bread-fruit, especially some kinds of fig-trees, among which is the *ficus Indica*, or banyan-tree. The areca-palm also grows on these islands. The mountains and hills are generally covered with high forest-trees, among which the cabbage-tree is common. The inhabitants belong to the Malay race, and go nearly naked: they are industrious agriculturists and fishermen. They make excellent mats, and canoes of a large size, with which they undertake voyages of several hundred miles, visiting from time to time the Spanish settlements of Guahan, to which they bring such articles of agricultural produce as will bear the voyage. They are governed by kings: the government is not strictly hereditary, but partly elective. [Lütke, *Voyage autour du Monde*.]

PHILIPPUS was also the name assumed by the impostor Andriscus, who, by pretending to be the son of King Perseus, induced the Macedonians to acknowledge him as their king, and met with so much success as to defeat one of the Roman officers. But he was ultimately driven out of Macedon by Q. Caecilius Metellus, and given up to the Romans by a Thracian prince with whom he had taken refuge.

PHILIPPUS, M. JULIUS, a native of Bostra in Trachonitis, according to some authorities, after serving with distinction in the Roman armies, was promoted by the later Gordianus to the command of the imperial guards after the death of Misitheus, A.D. 243. [GORDIANUS; MARCUS ANTONINUS PIUS.] In the following year he accompanied Gordianus in his expedition into Persia, when he contrived to excite a mutiny among the soldiers, by complaining that the emperor was too young to lead an army in such a difficult undertaking. The mutineers obliged Gordianus to acknowledge Philippus as his colleague; and in a short time, Philippus wishing to reign alone, caused Gordianus to be murdered (Capitolinus, in *Historia Augusta*). In a letter to the senate, he ascribed the death of Gordianus to illness, and the senate acknowledged him as emperor. Having made peace with the Persians, he led the army back into Syria, and arrived at Antioch for the Easter solemnities. Eusebius, who with Orosius, Zonaras, and other Christian writers, maintains that Philippus was a Christian, states merely as a report that he went with his wife to attend the Christian worship at Antioch, but that Babila, bishop of that city, refused to permit him to enter the church, as being guilty of murder, upon which Philippus acknowledged his guilt, and placed himself in the ranks of the penitents. This circumstance is also stated by John Chrysostom. From Antioch, Philippus came to Rome, and the following year, A.D. 245, assumed the consulship with T. F. Titianus, and marched against the Carpi, who had invaded Mœsia, and defeated them. In the year 247 Philippus was again consul, with his son of the same name as himself, and their consulship was continued to the following year, when Philippus celebrated with great splendour the thousandth anniversary of the building of Rome. An immense number of wild beasts were brought forth and slaughtered in the amphitheatres and circus. In the next, under the consulship of Æmilianus and Aquilinus, a revolt broke out among the legions on the Danube, who proclaimed emperor a centurion named Carvilius Marinus, whom however the soldiers killed shortly after. Philippus, alarmed at the state of those provinces, sent thither Decius as commander, but Decius had no sooner arrived at his post than the soldiers proclaimed him emperor. Philippus marched against Decius, leaving his son at Rome. The two armies met near Verona, where Philippus was defeated and killed, as some say by his own troops. On the news reaching Rome, the prætorians killed his son also, and Decius was acknowledged emperor A.D. 249. Eutropius states that both Philippi, father and son, were numbered among the gods. It is doubtful whether Philippus was really a Christian, but it seems certain, as stated by Eusebius and Dionysius of Alexandria, that under his reign the Christians enjoyed full toleration and were allowed to preach publicly. Gregory of Nyssa states that during that period all the inhabitants of Neocæsarea in Pontus embraced Christianity, overthrew the idols, and raised temples to the God of the Christians. It appears that Philippus during his five years' reign governed with mildness and justice, and was generally popular.

Coin of Philippus the Younger.
British Museum. Actual Size.

PHILI'PPUS (Φίλιππος), the name of several antient physicians enumerated by Fabricius (*Biblioth. Græca*). The most celebrated is Philippus of Acarnania, the friend and physician of Alexander the Great, who was the means of saving the king's life when he had been seized with a violent attack of fever, brought on by the excessive coldness of the waters of the river Cydnus, Ol. 111, 4 (B.C. 333). Parmenio sent to warn Alexander that Philippus had been bribed by Darius to poison him; the king however did not doubt his fidelity, but, while he drank the draught prepared for him, put into his physician's hands the letter he had just received. His speedy recovery fully justified his confidence, and proved at once the skill and honesty of Philippus. (Q. Curt., lib. iii., cap. 6; Val. Max., lib. iii., cap. 8, in fine; Plut., cap. 19; Arrian, lib. ii., cap. 4; Justin, lib. xi., cap. 8; Diod. Sic., lib. xvii., cap. 31.)

PHILIPS, AMBROSE, was born about the year 1671, and is said to have been descended from an old Leicestershire family. He was educated at St. John's College, Cambridge, and his first printed performance is a copy of English verses in the Collection published by that university on the death of Queen Mary, in 1695. From this date nothing is known of him till the appearance of his six Pastorals, which, Johnson observes, he must have published before the year 1708, because they are evidently prior to those of Pope. They are spoken of in the 'Guardian' (No. 40) as having been published in the same volume with Pope's, that is, in Tonson's 'Miscellany,' which appeared in 1709, and probably they had not been printed before. Philips's next performance was his 'Letter from Copenhagen' (in verse) to the earl (afterwards duke) of Dorset, dated March 9, 1709, which was printed in the 12th No. of the 'Tatler' (May 7, 1709), with an introductory eulogium by Steele, who styles it 'as fine a winter-piece as we have ever had from any of the schools of the most learned painters.' He afterwards translated the 'Persian Tales' from the French for Tonson, and brought out an abridgment of Hacket's 'Life of Archbishop Williams.' The next event of his literary life, and, on the whole, perhaps the most considerable, was the production at Drury Lane, in February, 1712, of his tragedy of the 'Distressed Mother,' which, although little more than a translation of the 'Andromaque' of Racine, was received with great applause, and long continued to keep possession of the stage. Pope, who a year or two before had bestowed high praise upon the 'Letter from Copenhagen,' calling it the performance of a man 'who could write very nobly,' but who had now been divided from Philips partly by feelings of poetical rivalry and jealousy, partly by their opposite party politics, told his friend Spence that the 'Distressed Mother' was in great part indebted for its success on the first night to a packed audience. The author's Whig friends certainly did their best for the play. It was elaborately praised, before its appearance, in the 290th No. of the 'Spectator' (for 1st February, 1712); and Addison, in the name of Budgell, wrote an epilogue for it, which took so greatly, that, according to Johnson, on 'the three first nights it was recited twice; and not only continued to be demanded through the run, as it is termed, of the play, but, whenever it is recalled to the stage, the epilogue is still expected, and is still spoken.' Other 'Spectators' were devoted (No. 335, for 25th March, 1712, by Addison) to an account of the strong impression made by the tragedy on Sir Roger de Coverley; and (Nos. 338, for 28th March, and 341, for 1st April) to an animated controversy about the merit of the epilogue, issuing of course in a triumphant vindication of it. A short time before, Philips's translation of 'Sappho's Hymn to Venus' had been printed, with strong commendation from Addison, both of that poem and of the author's 'admirable pastorals and winter-piece,' in the 'Spectator,' No. 223 (for 15th November, 1711); and the pastorals are again highly praised in Nos. 400 (for 9th June, 1712) and 523 (for 30th October), by Addison; and likewise in the 'Guardian,' No. 30 (for 15th April, 1713). But now Pope managed to play off a singular trick upon the guileless or careless nature of Steele, by imposing upon him as a serious critique an ironical discourse on Philips's Pastorals as compared with his own, in which, while the superiority was in terms assigned to Philips, every quotation and the whole treatment of the subject were artfully adapted to turn him into ridicule. It is surprising that any degree of simplicity could be so taken in; but Steele at once printed the paper, which forms the 40th No. of the 'Guardian' (for 27th April, 1713). Its appearance must at first have perplexed and puzzled the public; but Addison's quick eye detected at once the mockery which had escaped his more inattentive or more unsuspecting friend. This affair gave rise to an open feud between Pope and Philips, which was never healed. For many years Pope continued to make his unfortunate contemporary his butt; in particular, Philips's verses will be found to furnish, along with those of Blackmore, Theobald, and Welsted, the choicest specimens in the famous treatise of Martinus Scriblerus on the 'Art of Sinking in Poetry.' To all this persecution Philips had nothing to oppose but threats of personal chastisement, which had however the effect of making the satirist keep out of his way. Meanwhile his poetical reputation, which had previously been in a most flourishing condition, was undoubtedly very seriously damaged even by Pope's first insidious attack; he continued indeed to rhyme notwithstanding, but nothing which he produced after that paper in the 'Guardian' brought him much reputation. Conceiving himself to have a turn for simplicity and natural expression, he fell into a peculiar style of verse, in which the lines were very short, and the thoughts and phraseology approaching to the infantine; and this the public were taught to call 'Namby-pamby,' a name first bestowed, we believe, not, as has been stated, by Pope, but by Henry Carey, the clever author of 'Sally in our Alley' and 'Chrononhotonthologos,' a volume of poems published by whom in 1737 contained one so entitled in the form of a burlesque on one of Philips's productions. If the muses failed him however, Philips was consoled by the favour of his party and by considerable success as a politician. Soon after the accession of the House of Hanover, which fixed his Whig friends in power, he was made a commissioner of the lottery and one of the justices of the peace for Westminster, the latter, in those days, an appointment more lucrative than honourable. In 1721 he produced two more tragedies, 'The Briton,' and 'Humphrey, Duke of Gloucester,' both now forgotten. He next engaged in a periodical paper called 'The Freethinker,' in which one of his associates was Dr. Boulter, who was afterwards made bishop of Bristol and then archbishop of Armagh, and who, when he went over to Ireland, took Philips with him, and provided so well for him as to enable him to represent the county of Armagh in the Irish parliament. He at last rose to be judge of the Prerogative Court in Ireland; but resigned that place in 1748, and returned to his native country, where he died of a stroke of palsy, on the 8th of June, 1749.

PHILIPS, JOHN, was the son of Dr. Stephen Philips, archdeacon of Salop, and rector of Bampton in Oxfordshire, at which latter place he was born, in 1676. Having received his school education at Winchester, he was entered at Christ Church, Oxford, in 1694. It is said that he intended to follow the medical profession; but it does not appear that he pursued that object further than by engaging with much zeal in the study of botany and natural history. He first became known beyond his college, or university, by his poem entitled 'The Splendid Shilling,' which appeared in 1703. His intimate friend Edmund Smith says, in a fragment of a discourse on the works of Philips, which Dr. Johnson has printed, 'This poem was written for his own diversion, without any design of publication. It was communicated but to me; but soon spread, and fell into the hands of pirates. It was put out, vilely mangled, by Ben Bragge, and impudently said to be corrected by the author.' The 'Splendid Shilling' is a composition of the mock heroic kind, the verse being an imitation of that of Milton. Of course, it is absurd to contend, as has been done, that Philips here makes the little appear great, and is therefore to be distinguished from and set far above such parodists as only make the great appear little, as, for example, Cotton and Scarron. The truth is, that in both cases the great is made to appear little: what of piquancy there is in Philips's poem does not arise from any exaltation of the shilling, but from the application of the versification and expression of Milton to so mean a subject. In 1705 Philips produced his next poem, entitled 'Blenheim,' at the instigation, it is understood, of the Tory party, who wanted a poetical effusion on that victory to rival Addison's; but, notwithstanding an imitation of Milton of a more legitimate kind than in the 'Splendid Shilling,' Philips's 'Blenheim' found comparatively few admirers in that day, and has been generally forgotten since. His friend Smith attributes the general dislike of it partly to the circumstance of the author having been, like his prototype Milton, on the wrong side in politics, but principally to his readers having formed their taste upon French models, whence they had learned to admire points and turns, and consequently had no judgment of true greatness and majesty. Philips's chief work, his 'Cider,' a poem in two books, was published in 1706: like everything else that he wrote, it is in blank verse, and an echo of the numbers of 'Paradise Lost;' but, as a poetical composition, it belongs to the same class as Virgil's 'Georgics;' and consequently it is, as well as the 'Blenheim,' a serious, not a mock, imitation of Milton. Johnson says he was told by Miller, the eminent gardener and botanist, that there were many books written on the same subject in prose which do not contain so much truth as that poem. A complication of consumption and asthma put a period to the life of this amiable man, on the 15th of February, 1708, when he had just completed his thirty-second year. His friend and patron Sir Simon Harcourt, afterwards lord-chancellor, erected a monument to his memory in Westminster Abbey, which carries a long inscription in very flowing latinity, said by Johnson to be the composition of Bishop Atterbury, though commonly attributed to Dr. Friend. One passage is especially remarkable as expressing a notion of the perfection of verse, in which the writer of the inscription must have found himself widely at variance with the reigning taste of his day: Philips, he says, in the poetry he wrote in his native tongue, had learned, from the fountains of Greek and Roman song, to measure the harmony of verse 'rythmo . . . antiquo illo, libero, multiformi, ad res ipsas apto prorsus et attemperato, non numeris in eundem fere orbem redeuntibus, non clausularum similiter cadentium sono.' Curiously opposed to this stands the criticism of Johnson:—'Deformity is easily copied; and whatever there is in Milton which the reader wishes away, all that is obsolete, peculiar, or licentious, is accumulated with great care by Philips. Milton's verse was harmonious in proportion to the general state of our metre in Milton's age; and if he had written after the improvements made by Dryden, it is reasonable to believe that he would have admitted a more pleasing modulation of numbers into his work; but Philips sits down with a resolution to make no more music than he found—to want all that his master wanted, though he is very far from having what his master had. The asperities therefore that are venerable in the 'Paradise Lost,' are contemptible in the 'Blenheim.'' The insensibility which would have had Milton to take lessons in the music of verse from Dryden is startling enough; but there is justice in the contempt expressed for the mimetic Miltonism of Philips, who was without any true passion, or strength or elevation of fancy, and whose poetry in its most ambitious passages has little more than merely something in the sound to remind us of that of Milton.

PHILISTINES. [PALESTINE.]

PHILI'STION (Φιλιστίων), an antient Greek physician, the tutor of Eudoxus and Chrysippus. (Diog. Läert., *Vit. Philosoph.*, lib. viii., cap. 8, secs. 86 and 89.) He is called a Sicilian by Diogenes Läertius (lib. viii., sec. 86), but (if the same person be meant) he is said to have been an Italian by Rufus Ephesius (*De Corp. Hum. Part. Appell.*, p. 41, ed. Clinch), and a Locrian by Plutarch (*Sympos.*, lib. vii., quæst. 1, sec. 3), Aulus Gellius (*Noct. Att.*, lib. xvii., cap. 11, sec. 3), and Athenæus (*Deipnos.*, lib. iii., sec. 83, p. 115). He lived about the year 370 B.C, Ol. 102, 1. According to Plutarch and Aulus Gellius (*locis cit.*) he defended the opinion that part of what is drunk goes into the lungs, which is the more remarkable as Galen informs us that he was well skilled in anatomy. He belonged to the sect of the Empirici (Galen. *Subfig. Empir.* cap. i.), and was supposed by some persons to be the author of the treatise 'De Victu Salubri,' commonly attributed to Hippocrates. (Galen, *Opera*, tom. xv., p. 455; tom. xviii., A, p. 9, ed Kühn.) He is quoted several times by Pliny (*Hist. Nat.*, lib. xx., cap. 15, 34, 48, ed. Tauchn.); Oribasius (*De Machinam.* cap. iv.) attributes to him the invention of a machine for reducing luxations of the humerus; and (if the same person be meant) Athenæus (*Deipnos.*, lib. xii., sec. 12, p. 516) mentions him among those who had written on cookery (ὀψαρτυτικά).

PHILISTUS was a native of Syracuse, and a person of great wealth and influence. He was very intimate with the elder Dionysius, whom he assisted in obtaining the supreme power, B.C. 406; but having displeased the tyrant, he was banished from Syracuse. He retired to a city on the Adriatic Gulf, probably one of the Greek cities in southern Italy, and did not return to Syracuse till the accession of the younger Dionysius (Plutarch, *Dion.*, c. 11; Diod. Sic., xiii. 91), during whose reign the direction of public affairs appears to have been almost entirely in the hands of Philistus. When Syracuse was taken by Dion, B.C. 356, Philistus used great exertions in favour of Dionysius. He passed over into Italy, and procured from Rhegium alone 500 horse. After making an unsuccessful attempt upon Leontini, which had declared in favour of Dion, he joined Dionysius in the citadel, and was shortly after killed in a naval engagement, or, according to other accounts, was taken prisoner and put to death. (Plutarch, *Dion*, c. 35; Diod. Sic., xvi. 16.)

Philistus must have lived to a considerable age, since he was an eye-witness of the Athenian defeat at Syracuse, in B.C. 415, fifty-nine years before his death. (Plutarch, *Nic.*, c. 19.)

Philistus wrote a history of Sicily, which appears to have been a work of great merit, but of which we have only fragments. Cicero, in a letter to his brother (*ad Qu. Fr.*, ii. 13), speaks of the style of Philistus as brief and terse, and considers him as resembling though inferior to Thucydides; and in another passage (*Brut.*, c. 85) he also classes him with Thucydides, and says that these two writers were superior to all others. (Compare *De Div.*, i. 20; Quint., *Inst. Orat.*, x. i., p. 222, ed. Bipont.) The Sicilian history of Philistus was divided into two parts; of which the first contained seven and the second four books. (Diod. Sic., xiii. 103.) The first part embraced a period of 800 years, and terminated at the archonship of Callias and the battle of Agrigentum, that is, B.C. 406; the second part, which commenced at the point where the first terminated, contained the history of the elder Dionysius, and terminated at B.C. 363. (Diod. Sic., xv. 89; Clinton's *Fast. Hell.*, ii., p. 119.)

PHILLIPSITE, a mineral, the primary form of which is a right rhombic prism. It occurs crystallized only in macles which have much the appearance of harmotome; cleavage imperfect; fracture conchoidal; hardness 4·5. Scratches carbonate of lime. Colour white, flesh-red, or greyish. Streak white. Lustre vitreous. Transparent, translucent, opaque. Specific gravity 2·0 to 2·2.

This mineral occurs with gmelenite, in the county of Antrim, and at the Giant's Causeway; at Capo di Bove, near Rome; in Sicily; in the lavas of Vesuvius, and at Marburg in Hesse, &c.

Analysis of the mineral from the last-mentioned place, by Gmelin:—

Silica	.	48·02
Alumina	.	22·61
Potash	.	7·50
Lime	.	6·56
Water	.	16·75
		101·44

PHILLY'REA, the φιλλυρεα of Discorides, is a genus of Mediterranean evergreen shrubs, many varieties of which are cultivated in our gardens. They are much like the evergreen shrubs called Alaternus, from which however they are readily known by their leaves being opposite, not alternate. Some botanists regard them as species of olive, to the fruit of which that of the Phillyrea has much resemblance. The hardiest and handsomest variety is *P. obliqua*, the most tender and the least beautiful is *P. angustifolia*.

PHILO (Φίλων), the name of several antient physicians, though it is difficult to determine exactly how many. Fabririus (*Biblioth. Græca*) supposes four, of whom the most eminent was the author of the celebrated antidote called, after his name, Philonium. He left behind him directions for composing this medicine in a short Greek poem, of twenty-six lines, written in a very enigmatical style, which, together with an explanation of it, may be seen in Galen. (*De Compos. Medicam.*, κατὰ τόπους, lib. ix., cap. 4, p. 267, ed Kühn.) It seems to have been something like the Mithridate, the Theriaca, and the Hiera Archigenis, and was, as Galen tells us, one of the most antient as well as one of the most esteemed of this kind of medicines. Philo was born at Tarsus in Cilicia (Galen, *loco cit.*), and is supposed to have lived about the beginning of the Christian æra.

Another physician of this name, probably contemporary with Plutarch, in the second century A.D. is quoted by him (*Sympos.*, lib. viii., quæst. 9, sec. 1) as having said that Elephantiasis first appeared shortly before his time. In this opinion however he is probably mistaken. See a treatise by Jul. Alb. Hofmann, entitled 'Rabiei Caninæ ad Celsum usque Historia Critica,' Lips., 1826, 8vo., p. 53.

PHILO JUDÆUS, that is, Philo the Jew, was a native of Alexandria. The precise time of his birth is unknown; but he represents himself as of advanced age about A.D. 40, when he was sent as chief of an embassy from the Jews of Alexandria to the emperor Caligula, for the purpose of pleading their cause against Apion, who charged them with refusing to pay due honours to Cæsar. He went again to Rome in the reign of Claudius, and after this nothing is known with certainty about him.

Philo had a brother employed in the affairs of government at Alexandria, named Alexander Lysimachus, who is supposed to be the Alexander mentioned in *Acts*, iv. 6, as a man 'of the kindred of the high-priest.' That Philo was a member of the sacerdotal family is asserted by Eusebius and others, and his own writings indirectly testify that such was the fact. There is also reason to believe that he belonged to the sect of the Pharisees.

Philo was eminent for his learning and eloquence. To the attainments usually made by the Jews of his condition, he added an extensive knowledge of the Greek philosophy, and especially of that of Plato. He has been represented by Scaliger and Cudworth as ignorant of Jewish literature and customs; but Fabricius and Mangey have clearly shown that such representation is entirely groundless.

As an interpreter of the Jewish scriptures, he is fond of allegorising, a species of interpretation which had long prevailed at Alexandria. That Philo was a follower of Plato in philosophy there can be no doubt; but it must not therefore be concluded that his style is Platonic or his language Attic. He writes well indeed, but still as an Alexandrian Jew. Mangey styles him 'the chief of the Jewish, and not much inferior to the Christian writers.'

The principal editions of Philo are those of Geneva, 1613; Paris, 1640; Mangey, London, 1742; Richter, Leipzig, 1828-1830.

Mangey's edition, in two vols. folio, was printed by the learned William Bowyer. It is a splendid book, and does great honour to the English press. The works of Philo, as they are here presented, amount to forty-seven treatises, with six fragments, upon subjects mostly referring to the Jewish religion. The arrangement of these treatises appears to be arbitrary, and it would perhaps be impracticable to reduce them to order. This edition contains two treatises not before published, one on the 'Posterity of Cain,' from a MS. in the Vatican Library; the other on the 'Last Three Commandments,' from a MS. in the Bodleian. It is dedicated to Archbishop Potter, and a valuable preface follows the dedication.

Richter's edition, in 8 vols. small 8vo., follows Mangey's text, but does not give the Latin version. It contains two more tracts of Philo, on the 'Feast of the Basket' and on 'Honouring Parents,' which tracts Angelo Mai discovered in the Laurentian Library at Florence, and published with a Latin version, at Milan, in 1818. Richter's edition contains moreover a Latin translation of seven treatises of Philo existing in an Armenian version, supposed to have been made in the fourth or fifth century, and published in Armenian and Latin by John Baptist Aucher, at Venice, in 1822 and 1826.

Richter's publication is printed with great care, and may be pronounced the most complete and useful edition of Philo.

An ample account of Philo and his writings may be found in the 'Bibliotheca Græca' of Fabricius, and in Mangey's preface, whose materials are derived from Josephus, Justin Martyr, Clemens of Alexandria, Eusebius, Jerome, and others, including of course Philo himself. On the additional publications of Mai and Aucher, see *British Critic and Quarterly Theological Review*, vol. v., 1829.

PHILO. Many other Philos are named; but as they do not appear worthy of particular notice, it may suffice to state that a catalogue of them, to the number of more than forty, is given in the third volume of the 'Bibliotheca Græca' of Fabricius.

PHILODE'MUS was an Epicurean philosopher and poet, and is mentioned by Cicero and Horace. Fragments of his epigrams are in the Greek Anthology. (Fabricius, *Bibliotheca Græca.*)

PHILOLA'US, a native of Crotona, flourished about B.C. 374. He was a Pythagorean, a disciple of Archytas, and the first who wrote on the subject of physics. It is said that Plato bought, at an enormous price, three books of Philolaus, with the aid of which he composed his 'Timaeus.' In several antient writers quotations are made from Philolaus. (Fabricius, *Bibl. Græca.*)

PHILO'LOGY (φιλολογία). It is difficult to attach a precise meaning to this word, as it is used in different significations by different writers. Among the Greeks and Romans, the term philology was originally used to signify a love for the investigation of all subjects connected with literature. (Plat., *Theaet.*, c. x., p. 146; c. xlvii., p. 161; Cic. *ad Div.*, xvi. 21; Ernesti, *Clavis Ciceron.*, under φιλολογώτερα.) The Alexandrine critics applied the term philologus to a person who was well acquainted with the antient Greek writers and with the subjects treated of in their works; and we learn from Suetonius (*De Illustr. Grammat.*, c. 10) that Eratosthenes, who lived in the second century before the Christian æra, was the first who obtained this name, in consequence of his extensive and varied learning. In later times, a philologus was merely a person skilled in language, and the word became almost synonymous with grammaticus.

Some modern writers have included under the term philology the study of Greek and Roman antiquities, but the majority of writers appear to regard the study of the theory of language and of languages in general as the only subjects strictly belonging to philology.

The reader who wishes further information respecting the different meanings attached to the word philology, may consult Ast's 'Grundriss der Philologie,' Landshut, 1808, and the first essay in Wolf and Buttmann's 'Museum der Alterthums-Wissenschaft,' Berlin, 1807.

PHILOME'LA. [NIGHTINGALE; SYLVIADÆ.]

PHILOMELI'NÆ. [SYLVIADÆ.]

PHILOME'LUS. [PHOCIS.]

PHILOPŒMEN, the son of Craugis or Crausis of Megalopolis in Arcadia, was born about 253 B.C. Having lost his father when he was still a boy, he was educated by Cleander of Mantineia, an intimate friend of Crausis. He was afterwards placed under the tuition of Ecdemus and Demophanes, two distinguished citizens of Megalopolis and friends of Aratus. Philopœmen studied philosophy and the art of war, of which he was very fond from early youth: 'he considered it,' as Plutarch says, 'the most important and useful occupation of men, and despised those who were not versed in it.' When he attained the age of manhood, he engaged in predatory incursions which the people of Megalopolis, the constant enemies of Sparta, made into Laconica. In his leisure he applied himself to agricultural pursuits for the purpose of improving his paternal estate.

Philopœmen was thirty years of age when Cleomenes, king of Sparta, surprised Megalopolis by night [CLEOMENES' III.], and he was one of the last to leave the town. Some time after, the Achæans, in order to oppose Cleomenes, having by the advice of Aratus allied themselves with Antigonus Doson, king of Macedonia, that prince came into Peloponnesus, and defeated Cleomenes at the battle of Sellasia, 222 B.C., to which victory Philopœmen mainly contributed. He received a severe wound in this battle. His reputation now rose high, and he was offered by Antigonus a command in his army, which he declined, 'because,' says Plutarch, 'he could not bear to be under the direction of another.' Philopœmen now repaired to Creta, and engaged as a volunteer in the war which distracted that island. During this campaign he greatly improved himself in strategy. Aratus died B.C. 213, and Philopœmen, on his return home, was made general of the Achæan cavalry. He improved the discipline of that body, recruited its strength, and made it completely efficient. In a battle which was fought near the river Larissus, he defeated the united Ætolians and Eleans, and killed with his own hand Demophantus, the Elean general. He also effected many improvements in the tactics and discipline of the Achæan infantry, and introduced the Macedonian order of battle. War having broken out between the Achæans and Machanidas, tyrant of Sparta, Philopœmen marched against the Spartan, and defeated him near Mantineia. Machanidas fell in the battle, by the hand of Philopœmen. In consequence of this exploit, the Achæans voted him a statue of bronze, which was placed in the temple of Delphi. In 201 B.C. Philopœmen was made strategos, or captain-general, of the Achæan league, of which, from that time till his death, he was considered as the principal leader, having succeeded Aratus in the confidence of the people. Philopœmen being a great obstacle in the way of Philip of Macedonia, who wished to extend his sway over the independent states of Greece, the king tried to have him assassinated, but the plot was discovered, and only served to increase the influence of Philopœmen. Nabis, who had succeeded Machanidas as tyrant of Sparta, seized Messenia, but Philopœmen drove him out of that country, and restored the Messenians to their independence as allies of the Achæans. Wanting employment at home, he went a second time to Crete at the request of the Gortynians, and served in the wars of that island. Returning home about 197 B.C., he found Philip beaten by the Romans under Flamininus, and obliged to sue for peace, the Achæans allied to Rome, and Nabis at war both with the Achæans and with Rome. Philopœmen equipped a fleet against Nabis, but he failed in his naval operations. He then attacked him by land and defeated him; and Gythium and the other seaports of Laconica, being taken from Nabis, were occupied by Achæan garrisons under an agreement with Flamininus, the Roman commander. When Nabis was murdered by his Ætolian auxiliaries, 192 B.C., Philopœmen marched upon Sparta, which was in a state of great confusion, and obliged the citizens to join the Achæan League, which then included all the Peloponnesus, with the exception of Elis.

During the subsequent war between Antiochus and the Romans, Philopœmen, who was more clear-sighted than most of his countrymen with respect to the ambitious policy of Rome, recommended caution, and observed to Diophanes, who was then strategos of the Achæans, that 'while Antiochus and the Romans were contending with two such powerful armies in the heart of Greece, the duty of an Achæan general was to watch them attentively, and, instead of lighting up a fresh war at home, rather to overlook some real injuries.' This referred to Diophanes' marching against Sparta, which had withdrawn itself from the league. Some time after however the citizens of Sparta, impatient at being cut off from the sea-coast, attempted to surprise a seaport called Las, but were repulsed by the Achæans, joined to the Lacedæmonian emigrants who had been exiled by Nabis. The Achæans passed a decree requiring Sparta to give up the authors of the attempt upon Las. The pride of the Spartans was roused; they refused compliance, put to death several of their countrymen who were in favour of the Achæans, and sent envoys to the Roman Proconsul Fulvius, who had just effected the subjugation of the Ætolians, 189 B.C. Philopœmen, who was strategos of the Achæans for that year, devastated Laconica. Fulvius came into Peloponnesus, and advised both parties to send messengers to Rome, and to suspend hostilities. The Achæans sent Diophanes and Lycortas, the father of the historian Polybius. The senate returned an ambiguous answer, which the Achæans interpreted in their favour; and Philopœmen, being re-elected strategos for the following year, 188 B.C., marched into Laconica, and again demanded the authors of the attack upon Las and of the withdrawal from the Achæan alliance, with a promise that they should not be punished without trial. Upon this several of the persons implicated in this affair came forward and went voluntarily to the Achæan camp, accompanied by others of the principal citizens of Sparta. As they approached the Achæan camp, the emigrants who formed the Achæan advanced-guard fell upon their own countrymen, and killed seventeen of them, when Philopœmen interfered and saved the rest (sixty-three in number) from immediate destruction. The next day he brought them before the assembled Achæans and Lacedæmonian emigrants, and, after a mock trial, they were sentenced to death and executed. The Spartans in dismay submitted to Philopœmen, who dictated to them hard conditions, namely, that the walls of the town should be razed, that all emigrants should be restored, that all the mercenary troops should quit Laconica, as well as all the slaves who had been emancipated by Nabis and other tyrants. About 3000 of these refusing to leave the country, Philopœmen sold them, and applied the money thus produced to rebuilding a portico in Megalopolis which had been destroyed by Cleomenes. But the hardest condition which Philopœmen imposed upon Sparta was that of abolishing the laws and discipline of Lycurgus, and obliging the Spartans to adopt the institutions of the Achæans and bring up their children after the Achæan fashion, being convinced, says Plutarch, 'that their spirit could never be humbled so long as they adhered to their old institutions.' Thus, in the year 188 B.C., the laws of Lycurgus were abrogated, after having subsisted for seven centuries, during which Sparta had maintained a proud station among the states of Greece. It is true that for a long time previous to their abrogation they had been ill observed, but still they existed, at least in name, and it required only a determined spirit like that of Cleomenes to enforce obedience to them. The Spartans again appealed to Rome, and the consul Q. C. Metellus, on his return from Macedonia, where he had been on an embassy, appeared before the council of the Achæans assembled at Argos, and complained that they had treated the Spartans with undue severity. Aristænus, the Strategos for the year, was in the Roman interest, and Diophanes also blamed the conduct of Philopœmen; but Lycortas defended his conduct, and the council resolved that the decree concerning Sparta should not be repealed. It was perhaps on this occasion that Philopœmen, indignant at the servility exhibited by Aristænus towards the Romans, is reported by Plutarch to have exclaimed, 'And why in such haste, wretched man, to see an end of Greece?' Envoys were sent to Rome by the Achæans to justify their conduct, and the Spartans, on their side, sent two of the restored exiles, who took a violent part against the Achæans. The senate, having heard both parties, sent Appius Claudius and others as commissioners to the Peloponnesus. A general congress of the Achæans being called, Appius Claudius declared that the senate was displeased with the manner in which Sparta had been treated, the massacre of eighty of its citizens, the demolition of its walls, and the abrogation of the laws of Lycurgus. It was on this occasion that Lycortas made that eloquent speech in reply which is given by Livy (xxxix. 36, 37), in which, after defending the conduct of the Achæans, he retorted upon the Romans their own conduct towards the free state of Capua during the second Punic war. The speech of Lycortas was generally approved; 'so that,' adds Livy, 'it was easy for Appius to see that the dignity of Rome could not be upheld by gentle proceedings.' Accordingly Appius haughtily advised the Achæans to do with a good grace that which otherwise they would be obliged to do against their will. The congress then declared, that rather than reverse their own decrees, they left it to the senate to make what changes they thought proper. The senate, seemingly satisfied with this submission, allowed Sparta to continue in the Achæan league, on the condition of a general amnesty and the restoration of all political exiles.

In the year beginning May, 183 B C., Philopœmen, then seventy years of age, was elected strategos for the eighth time. About this time Messene, through the influence of one of its citizens named Dinocrates, threw off its alliance with the Achæans. It appears from some passages of Polybius that Dinocrates was a friend of Flamininus, the Roman general, who had been just appointed ambassador to Prusias, king of Bithynia, to demand of him the person of Hannibal. Flamininus on former occasions had shown that he was no friend to Philopœmen, and indeed the personal character of the latter made him obnoxious to the Roman policy. Flamininus, on arriving at Naupactus, wrote to Philopœmen, requesting him to call together a general congress of the Achæans to discuss the affairs of Messene. Philopœmen, knowing that he had no instructions from the senate for the purpose, declined to do so, and prepared for war against Messene. He marched with a body of cavalry, but finding a stout resistance, he was obliged to fall back. Being the last to retire, he was surrounded by the enemy, thrown from his horse, wounded in the fall, and taken prisoner to Messene. The citizens of Messene felt for his age and his misfortune, but a few of the leading men of the faction of Dinocrates determined on getting rid of him. They put him in a dark dungeon called 'the Treasury,' and in the night they sent the executioner to him with a cup of poison. Philopœmen asked the man whether he knew what had become of the Achæan cavalry, and especially of his friend Lycortas? The man answered that they had retired in safety. 'Then we are not altogether unhappy,' observed the aged general, and he took the cup and drank the poison, which soon put an end to his life (182 B.C.). The news spread rapidly through Achæa. Lycortas, being appointed strategos, marched to avenge the death of his friend. The Messenians opened their gates, Dinocrates killed himself, and the remains of Philopœmen being burned, the ashes were collected in an urn, which was carried by young Polybius in solemn procession of the Achæan army to Megalopolis. The Messenian prisoners who had been concerned in the death of Philopœmen were stoned to death. Statues to his honour were set up in most Grecian cities. Philopœmen has been styled by some the last of the Greeks: he was certainly the last of their successful commanders.

(Plutarch, *Philopœmen;* Polybius, xxiii.; *Fragments,* xxiv. 5; Livy, xxxix.)

PHILO'SCIA. [Isopoda, vol. xiii., p. 55.]

PHILOSOPHY, from the Greek *philosophia* (φιλοσοφία), literally signifies 'love of wisdom or knowledge,' and a philosopher (φιλόσαφος) is a 'lover of wisdom.' Pythagoras (Diog. Laert., *Proœm.*) is said to have first used the term philosophy, and to have called himself a philosopher, instead of a sophus (σόφος), or 'wise man,' for, he added, no one is wise but God. Among the Greeks, philosophy was sometimes viewed as comprising or consisting of three parts, physic (φυσικόν), ethic (ἠθικόν), and dialectic (διαλεκτικόν). Physic treated of the universe and that which it contained; ethic treated of things that concerned human life and man. The term dialectic is explained in the article Organon. This division of philosophy is in itself of no value, and is merely a matter of history.

The terms philosophy, philosophical, philosopher, are often used in our own language apparently with no great precision, though it is not difficult to deduce from the use of these terms the general meaning or notion which is attached to them. We speak of the philosophy of the human mind as being of all philosophies that to which the name philosophy is particularly appropriated; and when the term philosophy is used absolutely, this seems to be the philosophy that is spoken of. Other philosophies are referred to their several objects by qualifying terms: thus we speak of natural philosophy, meaning thereby the philosophy (whatever that word may mean) of nature, that is, as the term nature is generally understood, of material objects. We also speak of the philosophy of positive law, understanding thereby the philosophy of those binding rules, properly called laws. The terms philosophy of history, philosophy of manufactures, and other such terms, are also used. All objects then which can occupy the mind may have something in common, called their philosophy; which philosophy is nothing else than the general expression for that effort of the mind whereby it strives, pursuant to its laws, to reduce its knowledge to the form of ultimate truths or principles, and to determine the immutable relations which exist between things as it conceives them. The philosophy which comprises within itself all philosophies is that which labours to determine the laws or ultimate principles in obedience to which the mind itself operates; and both those laws or ultimate truths, which must be considered as constituting the mind what it is, and which are therefore independent of all external impressions, and those laws by which the mind operates upon the sensuous impressions produced by objects which it conceives and can only conceive as being external to itself.

Thus every kind of knowledge, the objects of which are things external, has its philosophy or principles, which, when discovered and systematised, form the science of the things to which they severally belong. But inasmuch as the mind, in striving after this science, must act by its own laws and powers, and as these must in their form, viewed independently of their special objects, always be the same laws and powers (for we cannot conceive the mental powers to vary or differ in their essential qualities merely because they are applied to things that are conceived as different), we therefore assume that the mind has its laws and powers, which may be discovered by observation, as we discover by observation the laws or principles which govern the relations of things external to the mind, or conceived as external. Thus the human mind, by the necessity imprinted upon it, seeks to discover the ultimate foundation of all that it knows or conceives; to discover what itself is, and what is its relation to all things. Accordingly it strives to form a system out of all such ultimate laws or principles. Such a system may be called a philosophy, in the proper and absolute sense of the term, and the attempt to form such a system is to philosophise. Systems of philosophy have existed in all nations; even in the most uncivilised, in some form, and particularly in the form of a religion; for the highest aim of philosophy is to ascertain the relation of man to the infinite Being whom he conceives as the end and limit of all his inquiries. In nations which have made further progress in mental culture, the systems of philosophy are not limited to the dogmas of a religion, but those who have leisure, and whose minds have been disciplined, have in all ages ventured to transcend the limits of the religious system of their society or age, and to form what are called philosophical systems. The history of such systems is the history of philophy, which thus viewed is a history of the progress of the human mind towards the knowledge of itself, a knowledge which, imperfect as it is, is the accumulation of many centuries, and the work of many contributors.

PHILOSTO'RGIUS, a native of Cappadocia, born A.D 364, came to Constantinople to complete his studies, and afterwards wrote a History of the Church, in twelve books, from the beginning of the schism of Arius, to A.D. 425. The work is lost, but we have an epitome of it by Photius, independent of a short notice of it in his 'Bibliotheca.' (*Myriobiblon*, Cod. 40.) Photius inveighs against the author as a heretic, and an apologist of Arius, Eusebius of Nicomedia, Apollinaris, and other heretics. Philostorgius was a man of general information, and he inserted in his narrative many geographical and other details of remote countries, especially of Asia and Africa. The author was rather credulous with regard to prodigies, monsters, and other wonderful things, and Photius censures his credulity in attributing miracles to those whom the Patriarch considered as heretics. The epitome was translated into Latin, with comments, by J. Gothofredus, 4to., Geneva, 1642, and also by H. de Valois, 'Compendium Historiæ Ecclesiasticæ Philostorgii, quod dictavit Photius Patriarcha,' Paris, 1673, with notes. It has also been translated into French: 'Abregé de l'Histoire de l'Eglise de Philostorge,' Paris, 1676.

PHILO'STRATUS, FLAVIUS, a native of the island of Lemnos, born in the second half of the second century of our æra, taught rhetoric first at Athens and afterwards at Rome, where he became known and was patronised by the empress Julia, the wife of Septimius Severus, who was partial to the learned. She commissioned him to compile the biography of Apollonius of Tyana from some memoirs written by a certain Damis of Nineveh, who had accompanied Philostratus in his peregrinations, and which had come into her possession. Philostratus professes also to have used in his compilation a collection of letters of Apollonius, which were at one time in the possession of Hadrian, and were placed by that emperor in his palace at Antium, together with certain responses of the Oracle of Trophonius, which Apollonius had also collected. The biographer availed himself also, according to his own statement, of the narrative of a certain Maximus who had known Apollonius. [APOLLONIUS OF TYANA.] The book of Philostratus displays great credulity, either real or affected, in the compiler, and a great want of critical discrimination; it also contains many anachronisms and geographical errors. Huet and others have imagined that the object of Philostratus was to write a parody of the life of Christ, but this seems doubtful: the parody, if intended as such, is too gross; besides which, it appears from the testimony of Lampridius (*Life of Alex. Severus*), that Christ was really worshipped by some of the later heathen emperors, together with Abraham, Orpheus, and Apollonius, these being all looked upon as holy men and tutelary genii. That Apollonius of Tyana was a real character, a philosopher, and a traveller, appears from various passages of antient authors. Vopiscus, among others, in his Life of Aurelian, says that his statues were in many temples; but his adventures were probably magnified and distorted in course of time, and it is remarkable that no one mentions him until nearly a century after the time assigned for his death. The empress Julia, a Syrian by birth, was probably fond of the marvellous, and Philostratus, intending to entertain her, inserted in his book all the wonderful stories he could collect relative to his hero. It seems however that in the time of the great struggle between the heathen and Christian religions, under Diocletian and his immediate successors, some of the heathen writers thought of availing themselves of the Life of Apollonius as a kind of counterpoise to the Gospel narrative. Hierocles, prefect of Alexandria, and an enemy of the Christians, wrote a book with that object, in the shape of a comparison between the Life of Apollonius by Philostratus and that of Christ, of which book Eusebius wrote a refutation: 'Eusebii Pamphili Animadversiones in Philostrati de Apollonio Tyanensi Commentarios ob institutam cum illo ab Hierocle Christi comparationem, adornatæ.' Lactantius (*Divin. Instit.*, v. 3) also combats the same notion as absurd. St. Augustin (*Epist.* 4) alludes to Apollonius as a magician whom the heathens compared with Christ. (See Tillemont, *Hist. des Empereurs Romains*, vol. ii., and Bayle's article 'Apollonius de Tyane.')

The other works of Philostratus are: 1, 'The Lives of the Sophists,' in two books; 2, 'Heroica,' or comments on the lives of some of the heroes of Homer, in the shape of a dialogue; 3, 'Icones,' or descriptions of 64 paintings which were in a portico near Neapolis by the sea-shore (these descriptions contain valuable information concerning the state of antient art); 4, Epistles, mostly erotic, excepting a few on matters of literature: one, which is inscribed to Julia Augusta, is an apology for the sophists. Philostratus wrote other works, such as a 'Lexicon Rhetoricum,' orations, &c., which are lost. His nephew, who is styled Philostratus the Younger, and who lived under Macrinus and Elagabalus, wrote also a book of 'Icones,' which are not descriptions of actual paintings, but are so many subjects proposed to painters.

Olearius published all the existing works of the two Philostrati, with a Latin version, fol., Leipzig, 1709, including also some letters attributed to Apollonius and the work of Eusebius against Hierocles. The 'Heroica' of Philostratus were edited by Boissonade, Paris, 1806, 8vo., upon a collation of nine MSS. An edition of the 'Icones' of both the Philostrati appeared at Leipzig, 1825, 8vo., with a commentary by F. Jacobs, and notes by F. G. Welcker.

PHILO'TAS. [PARMENIO.]

PHILO'XENUS, a native of Eretria, was the pupil of Nicomachus of Thebes, whom he imitated, and even surpassed in rapidity of execution: he is said by Pliny (*Hist. Nat.*, xxxv. 10, 36) to have discovered some more expeditious methods of operation in painting. He was the most rapid painter of antiquity, the 'Fa presto' (Luca Giordano) of the antients.

Philoxenus was particularly distinguished for a Battle of Alexander and Darius, which, according to Pliny, was not inferior to any of the productions of antient painting. It was painted by order of Cassander, king of Macedon, and therefore probably not long after the hundred and sixteenth Olympiad, or 316 B.C.

It is not improbable that the large mosaic, apparently representing the battle of Issus, which was discovered in the year 1831, in Pompeii, in the so-called house 'del Fauno,' and is still preserved there, is a repetition of the celebrated picture by Philoxenus of that subject; for, independent of Alexander and Darius being the two most conspicuous figures, the design and composition of the work are so superior to the execution, that its original has evidently been the production of an age long anterior to the degenerate period of the mosaic itself. With the single exception of the execution, the mosaic exhibits, in every respect, merits of the highest order, and is certainly one of the most valuable relics of antient art: the composition is simple, forcible, and beautiful, and its original, if not actually a production of the most renowned times of Grecian painting, still cannot have been far short of meriting the commendation bestowed by Pliny upon the battle-piece of Philoxenus.

Pliny has mentioned only two works by Philoxenus, the one alluded to, and a lascivious piece, in which were three satyrs feasting, a style of art much in vogue with Grecian painters, even of the best days.

PHILTER (φίλτρον, *philtrum*), was a potion given among the Greeks and Romans to excite love. It is doubtful of what these potions were composed, but their operation was violent and dangerous, often depriving those who drank them of their reason. (Ovid, *Ar. Amat.*, ii. 106.) Lucretius is said to have died from drinking a potion of this kind, and the madness of Caligula is attributed by some to a similar potion, which was given him by his wife Cæsonia. (Suet., *Cal.*, 50; Juv., vi. 615, 616.) The most powerful love potions were prepared by the Thessalians, whence Juvenal speaks (vi. 610) of Thessala philtra.

PHI'LYRA, Fabricius's name for a genus of the tribe of *Leucosians*. [OXYSTOMES, vol. xvii., p. 110.]

The *Philyræ* are small crustaceans, with a circular and depressed *carapace*, the *front* of which is much less advanced than the epistome. The *external antennæ* are nearly transversal in flexion, and the buccal frame is nearly circular anteriorly; the principal portion of the external jaw-feet is triangular, as in the other Leucosians, but the palp or external branch of those organs is much dilated outwards, and describes a very curved line. *Feet* of the four last pairs with the tarsus depressed and nearly lamellar. Nothing else remarkable. (M. Edwards.)

Example, *Philyra scabriuscula.* (Pl. to M. Edwards's *Hist. Nat. des Crustacés*, pl. 20, figs. 9 and 10.) Colour rosy grey; length six lines.

Locality.—East Indies.

PHLEGM is the mucus secreted by the air passages. [MUCUS.] In its common acceptation the term includes nearly all materials coughed up from the lungs.

PHLEGON (Φλέγων), a native of Tralles in Lydia (Suidas), a freedman of the emperor Hadrian. (Vopiscus, *in Saturnino*, p. 245; Spartianus, *in Hadriano*, p. 8, et *in Severo*, p. 71, ed. Salmas., Par., 1620; Photii *Biblioth.*, cod. 97, p. 83, ed. Bekker.) Nothing is known of the events of his life, and the date of his death is uncertain: however, as one of his chronological works, which is no longer extant, carried the history down to Ol. 229.2—A.D. 141 (Suidas), he probably lived to the middle of the second century A.D. Some fragments of his works are all that remain; the longest belongs to a treatise *περὶ θαυμασίων*, 'De Mirabilibus.' It is a curious work, divided into thirty-five chapters (some of which are very short), and containing (as might be expected from the title) a great many absurd fables. The same may be said of a shorter fragment of four chapters, *περὶ μακροβιών*, 'De Longævis.' The third fragment that remains is a chapter *περὶ τῶν* 'Ολυμπίων, 'De Olympiis,' which is supposed by Salmasius (*Ad Spartian.*, p. 43) to be the preface to a lost work, 'De Olympionicis.' He mentions (*De Mirab.*, capp. 6-10) several curious cases of hermaphrodites (*ἀνδρόγυνοι*), or persons supposed to be women who afterwards turned out to be men. (For similar instances see *Cyclop. of Anat. and Physiol.*, art. 'Hermaphroditism,' p. 692, &c.) He quotes Craterus, the brother of King Antigonus (*De Mirab.*, cap. 32), as saying that he had known a person who, within seven years, was an infant, a youth, an adult, a father, an old man, and a corpse. (For similar instances see Good's *Study of Med.*, cl. v., ord. 2, gen. 2, sp. 1.) He gives several instances of monstrous births, and of three, four, and five children being born at once, and says, on the authority of Megasthenes, that the women at Palæa become mothers at six years old. (*Ibid.*, cap. 33.) He gives a list of persons who had lived more than a hundred years, but says that the Erythræan sibyl attained nearly the age of one thousand. (*De Longæv.*, cap. 4.) He speaks of a child who was able to converse with others when only nine-and-forty days old. (Steph. Byzant., *De Urb. in* Ταρραχίνῃ.)

But what has made Phlegon's name more familiar among the moderns is his being cited, though a heathen, as bearing witness to the accomplishment of Christian prophecies. (Origen, *Cont. Cels.*, lib. ii., § 14, p. 69, ed. Spencer., Cantab., 1677.) The passage referred to is as follows:—'Phlegon, in the thirteenth, or, as I think, the fourteenth book of his Chronicles, ascribes to Christ the knowledge of some future things, though he makes a mistake in the person, naming Peter instead of Jesus; and he allows that the things foretold came to pass.' Upon this Lardner remarks (*Credibility*, Pt. II., 'Heathen Testimonies,' ch. 13)—1, that Origen seems to have trusted to his memory in this quotation; 2, that if Phlegon named Peter instead of our Lord, it is a mark of carelessness and inaccuracy; 3, that, for want of seeing the passage more at length, we cannot form any clear judgment about it; 4, that Phlegon was so credulous, that his testimony concerning things of a marvellous nature must be of little weight; and 5, that Origen is the only person that has mentioned this. He concludes therefore that 'upon the whole this citation is of no great moment.' But there is another passage of this author which may be reckoned more material, as it has been supposed to relate to the miraculous darkness which prevailed at the time of our Lord's crucifixion. In St. Jerome's Latin version of the 'Chronicle' of Eusebius (p. 155, ed. Pont., Burdig., 1604), the passage occurs as follows:—'And so writes Phlegon, an excellent compiler of the Olympiads, in his thirteenth book, saying, "In the fourth year of the two hundred and second Olympiad there was a great and extraordinary eclipse of the sun, distinguished among all that had happened before. At the sixth hour the day was turned into dark night, so that the stars in the heavens were seen, and there was an earthquake in Bithynia which overthrew many houses in the city of Nice."' (Compare Origen, *Cont. Cels.*, lib. ii., § 33, p. 80; *Ib.*, § 59, p. 96; and other authorities quoted by Lardner.) This passage was the origin of a controversy in England in the early part of the last century between Mr. Whiston, Dr. Sykes, Mr. Chapman, and others, a long and complete account of which may be found in the English translation of Bayle's Dictionary, and in Chaufepié's Supplement to it. The immediate cause of the controversy was the omission of the passage in the eighth edition of Dr. S. Clarke's 'Boyle Lectures,' published soon after his death in 1732, although it had been inserted in the first edition, which came out in 1706. This was done at the persuasion of Dr. Sykes, who had suggested to Clarke that an undue stress had been laid upon the passage. But besides these, other and greater names are to be found in direct opposition to each other upon this question. The testimony of Phlegon is highly valued by Colonia (*La Relig. Chrét. autorisée par les Aut. Pay.*, vol. i., ch. 1, pp. 1-44); by Huet (*Demonstr. Evang.*, prop. 3, § 9, pp. 25-6); by Fabricius (*Bibliog. Gr.*, tom. iii., p. 403); by Petavius (*De Doctr. Temp.*, lib. xii., cap. 21, p. 458): on the other hand, it is rejected by G. J. Vossius (*Harm. Evang.*, lib. ii., cap. 10); by Scaliger (in Euseb. *Chron.* pp. 185-6); by Kepler (*Ecl. Chron.*, pp. 87, 126); by Tillemont (*Mém. Eccles.*, Note xxxv., sur N. S. Jesus Christ, p. 449); by Bayle (*Dict. Hist. and Crit.*, art. 'Phlegon'); and by Lardner (*loco cit.*). The principal objections against the authority of the passage in question are thus briefly summed up by Dr. Adam Clarke (*Comment. on Matth.* xxvii. 45):—1, All the authors who quote Phlegon differ and often very materially, in what they say was found in him; 2, He says nothing of *Judæa*: what he says is, that in such an Olympiad (some say the 102nd, others the 202nd) there was *an eclipse in Bithynia*, and *an earthquake at Nice*; 3, He does not say that the earthquake happened at the time of the eclipse; 4, He does not intimate that this *darkness* was *extraordinary*, or that the eclipse happened at the *full of the moon*, or that it lasted *three hours*; all of which circumstances could not have been omitted by him if he had known them; 5, He speaks merely of an ordinary though perhaps total eclipse of the sun, and cannot mean the darkness mentioned by the Evangelists; and 6, He speaks of an eclipse that happened in some year of the 102nd or 202nd Olympiad, and therefore, upon the whole, little stress can be laid on what he says as applying to this event.

The three remaining fragments of Phlegon were first published in 1568, Basil., 8vo., Gr. et Lat., by Xylander, together with Antonini Liberalis *Transform. Conger.*; Apollonii *Hist. Mirab.*; Antigoni Carystii *Hist. Mirab.*; and M. Antoninus, *De Vitâ suâ.* An improved edition, with notes by Meursius, appeared in 1620, Lugd. Bat., 4to., Gr. et Lat., which is reprinted by Gronovius, in his 'Thesaur. Antiquit. Græc.,' vol. viii., p. 2690, sq., and p. 2727, and vol. ix., p. 1289, sq.; and also inserted among the works of Meursius, vol. vii., p. 77, sq. This was republished with notes by J. G. Franzius, and an 'Epistola de Longævis,' by Meibomius, Halæ, 1775, 8vo., and lastly, with additional observations, by J. Bastius, Halæ, 1822, 8vo., Gr. et. Lat.

PHLEGRÆI CAMPI, the antient name given by poets to a volcanic hilly region situated west of the city of Naples, embracing the not yet extinct volcano called La Solfatara, the basins of the lakes of Agnano and Averno, the extinct crater called Degli Astruni, that called Monte Barbaro, and the hill called Monte Nuovo, which was thrown up by an eruption in 1538 on the site of the former lake Lucrinus [AGNANO; AVERNO]; in short, the whole district round Pozzuolo, bounded on the east by the hill of Posilipo, which separates it from the basin of Naples Proper, and Mount Gaurus and Mount Grillo on the west and southwest, which divide it from the coasts of Cumæ and Baiæ. [BAIÆ; CUMÆ.] On the north this volcanic district is bounded by the plain of Campania. It must not be supposed however that the Phlegræi Campi constitute the whole volcanic region west of Naples, which extends on the other side of the hills of Baiæ and south-west to the Monte di Procida, and also beyond the narrow channel called

Bocche di Procida, including the island of that name and the neighbouring island of Ischia. [Ischia.] Breislak, in his 'Topografia Fisica della Campania,' gives a good description of this volcanic tract, with a map of it. See also G. Poulett Scrope, 'On the Volcanic District of Naples,' in vol. ii. of the second series of the 'Geological Transactions.'

With the exception of the hill of Solfatara, about 300 feet in height, which emits almost continually a sulphureous steam through several fissures, the other craters of this region have been long extinct.

Poetical descriptions of the volcanic phenomena exhibited by the Phlegræi Campi have been given by Virgil, Petronius Arbiter, and other Latin poets. Diodorus Siculus (iv. 21) says that this region, in which Hercules defeated the giants, was called 'Phlegræus Campus, from a hill which once threw up flames in the same manner as Ætna, retaining still the traces of former eruptions.' This hill was probably that now called Solfatara, though Diodorus adds, that 'in his time it was called Vesuvius;' but this must be an error either of the author or of the copyist, as Vesuvius, in the time of Diodorus, had not begun to vomit flames. Besides this, Diodorus characterises the region, which he describes as being near the shore of Cumæ, which description could not apply to Vesuvius. Strabo (p. 245. Casaub.) says that the Cumæa, as some suppose, was called Phlegra from the circumstance of its being full of sulphur, and fire, and hot springs.

PHLEUM, a genus of grasses, contains, among many unimportant species, one of considerable agricultural value. This, the *P. pratense*, or meadow cat's-tail grass, is a general inhabitant of the most fertile pastures, and is regarded as a sign of rich soil. It bears its flowers in a long cylindrical soft head, and is extremely like the meadow foxtail [Alopecurus] in appearance; from which it differs in having unequal glumes, and two paleæ instead of one. This plant is very productive, especially in the early spring, and is a very general component of hay. Nevertheless, according to Mr. Low, it is not a peculiarly good hay-grass, from the wiryness of its stem and the shortness of its aftermath. It is of the greatest use when the object is to procure a sward of permanent herbage.

PHLŒOMYS, Mr. Waterhouse's name for a subgenus of *Muridæ*, which is in the habit of feeding chiefly on the bark of trees, according to Mr. Cuming, after whom the typical species (*Mus* (*Phlœomys*) *Cumingi*) is named.

Locality.—The Island of Luzon. (See further, *Zool. Proc.*, 1839.)

PHLOGISTICATED AIR. [Azote.]

PHLOGISTON, an hypothetical substance, by supposing the existence of which Stahl [Stahl] explained the phenomena of combustion. He imagined that by combination with phlogiston a body was rendered combustible, and that its disengagement occasioned combustion, and after its evolution there remained either an acid or an earth: thus sulphur was by this theory supposed to be composed of phlogiston and sulphuric acid; and lead, of the calx of lead and phlogiston, &c.

At this period however oxygen had not been discovered, and although Jean Rey had shown that metals by burning increased in weight, and Hooke and Mayow had attributed combustion to the presence of the air in which it occurs, yet the doctrine proposed by Stahl maintained its ground for about half a century. Soon after the discovery of oxygen gas by Dr. Priestley, the experiments which others had made on the calcination of the metals were repeated with great accuracy by Lavoisier; the consequence was, that the phlogistic theory gave way to the antiphlogistic: for the combustion, which had been attributed to the extrication of phlogiston, was known in all common cases to be derived from the absorption of oxygen, and this explained the increase of weight which bodies acquired by combustion, whereas on the phlogistic theory they ought to have suffered a diminution by the process.

PHLORIZIN, a peculiar vegetable matter which exists in the bark of the trunk and roots of the apple, pear, cherry, and plum trees. According to Stass, it is most readily obtained, and in large quantity, by treating either the fresh or dried roots of the apple tree with weak alcohol at the temperature of about 150° Fahr. When the digestion has been continued for some hours, the clear solution is to be poured off, and the alcohol distilled; the residual liquor on cooling deposits phlorizin, which is to be rendered colourless by animal charcoal.

Phlorizin, when deposited from a saturated solution, has the form of silky tufts; but when obtained by the slow cooling of a dilute solution, it is in long flat brilliant needles. The taste of phlorizin is rather bitter, followed with slight sweetness; it is scarcely soluble in cold water, but boiling water dissolves it in large quantity; alcohol and pyroxylic spirit also readily take it up, and at all temperatures; æther, even when boiling, dissolves only traces of it, though, when mixed with alcohol, it dissolves it very well; it has no action on vegetable colours.

Phlorizin contains no azote, but, according to Stass, is composed nearly of—

Hydrogen . .	5·4	
Carbon . . .	58·6	
Oxygen . . .	36·0	
		100

Phlorizin is by various processes, described by M. Stass, converted into *phlorizein*, *phloretin*, and *phloretic acid:* for an account of these, we refer to his memoir contained in the 69th vol. of 'Annales de Chimie et de Physique.'

PHOCA. [Seals.]

PHOCÆA. [Ionia; Marseille.]

PHOCÆ'NA, Cuvier's name for the *Porpesses*, *Marsouins* of the French. [Whales.]

PHOCAS, a native of Asia Minor, of an obscure family, entered the army under the reign of the emperor Mauritius, and attained the rank of a centurion. He happened to be with his company on the banks of the Danube when one of those mutinies so frequent in the history of the Eastern empire broke out among the troops on that station, and having probably made himself conspicuous among the disaffected, he was tumultuously proclaimed leader of the insurgents, and he marched with them to Constanstinople. At the approach of the rebels an insurrection broke out in the capital, and the emperor and his family were obliged to escape in a boat to Calchedon. Phocas was proclaimed emperor and crowned by the patriarch, A.D. 602. Mauritius, being taken, was put to death, together with his five sons, and some time after the rest of his family shared the same fate. Phocas sent ambassadors to Khosru II. to announce his accession to the throne, but the Persian monarch having learned the circumstances, took up arms to avenge the cause of Mauritius, and carried on a destructive war in the Asiatic provinces. Phocas found more favour with Rome. Gregory I. wrote him some complimentary letters in which he extols the condition of the Italian subjects of the empire as being free men in comparison with those who were subject to the Longobard and other kings, who treated them as little better than slaves. These letters of Gregory to Phocas and his wife Leontia have been much censured, but we ought to consider that the Roman pontiffs, being at a distance from the Eastern capital, were not competent judges of the frequent insurrections and changes of dynasty which occurred there, while, exposed as they and their flocks were to eminent danger from the Longobards, it was their interest to propitiate the Byzantine ruler for the time being, without investigating too closely his title to the throne.

Phocas remained on good terms with Boniface III. and Boniface IV., the successors of Gregory. He is said by Anastasius, the Papal chronicler, to have acknowledged Boniface III. as the head of all the Christian churches; but that which is better authenticated is his act of donation of the Pantheon at Rome to Boniface IV., to be transformed into a Christian church, A.D. 607.

In the mean time insurrections broke out in several parts of the Eastern empire, which the suspicions and cruelties of Phocas only served to exasperate. Heraclius, exarch of Africa, sent two expeditions, one by sea and the other by land, under his son Heraclius and his nephew Nicetas, who joining before Constantinople, took possession of the city, after some resistance. Phocas was taken and put to a cruel death by order of the younger Heraclius, who succeeded him in the empire, A.D. 610.

(Cedrenus (Xylandri), p. 331, &c.; Gibbon.)

PHOCENIC ACID and **PHOCENIN**. This last is a peculiar fatty matter contained in the oil of the porpoise, combined with olein and a very small quantity of phocenic acid. To procure it, nine parts of the oil are to be treated with ten parts of hot alcohol of sp. gr. 0·797: the liquor, when it has become cold and clear, is to be submitted to distillation, by which an acid of an oleaginous appearance is obtained: if the acid is separated by carbonate of magnesia, and the remaining oil treated with cold weak alcohol, the phocenin is dissolved by it, and it has the following properties:—at 65° its sp. gr. is 0·954; it exhales a weak peculiar odour, somewhat resembling that of æther and phocenic, acid. It is insoluble in water, but very soluble in boiling alcohol.

When 100 parts of phocenin are treated with potash, they are converted into 59 parts of hydrated oleic acid, 15 of glycerin, and 32·82 of dry phocenic acid.

Phocenic Acid is colourless, liquid at usual temperatures, and in appearance resembles a volatile oil; its sp. gr. is about 0·932. It has a very strong smell, and its taste is sour and penetrating. It remains liquid below 32°, and boils at about 212°. It may be distilled in vacuo without alteration; but when distilled in a retort containing air, it is considerably altered, unless distilled with water, and then it rises with it, and it is condensed in a pure state in the receiver. It is nearly as combustible as volatile oils.

According to Chevreul, it is composed of—

Hydrogen . .	8·25
Carbon . . .	65·
Oxygen . . .	26·75
	100

PHOCIAN WAR. [PHILIP (of Macedonia); PHOCIS.]

PHO'CIDÆ. [SEALS.]

PHO'CION (Φωκίων), an Athenian general and statesman, was a contemporary of Demosthenes. His first appearance in history is at the battle of Naxos, B.C. 376, when Demosthenes was seven years old, being himself twenty-seven. He survived Demosthenes four years, and, according to Mr. Thirlwall, is the representative of that party in Athens to which Demosthenes was the constant antagonist.

Plutarch relates that Phocion was the son of a turner, but he disbelieves the story on account of the goodness of his education and the liberal turn of his mind. Whatever was his rank, Phocion found admittance into the school of Plato, and afterwards studied under Xenocrates, whose lessons had perhaps greater influence on his character than even those of Plato; at least it is not difficult to trace a resemblance between Phocion and Xenocrates, while it would be hard to acknowledge any between Phocion and Plato. To a stern and forbidding aspect, a stoical demeanour, and habits of rigid simplicity, Phocion united a kind and generous heart. These qualities secured for him so great a measure of popularity that he was forty-four times elected general, and that in an age when public offices were generally obtained by bribery. He was also heard with so much attention in public, that even Demosthenes dreaded the effect of his terse and pithy harangues.

Plutarch records many of his sayings. There is much wit and point in most of them, indeed they go quite beyond the style of antique jokes, usually so dull to modern ears, and there is much political wisdom in them; but still they have an air of intended wit and a striving after effect which make them look different from the strong and genuine thoughts of an earnest and true-hearted patriot. But after all, when biographer and subject each lived in an age more distinguished for smartness than solidity, we need not hold these speeches inconsistent with that high character for wisdom which Phocion bears.

The public incidents recorded of Phocion's life are, as is natural for the head of the peace party, not numerous. He commanded many times and often successfully, but he seems to have acted the part of an ambassador better than of a general. His death (B.C. 317) took place under circumstances much like those which accompanied that of Socrates. During the confusion which ensued after the death of Alexander, a revolution occurred at Athens, and the democratic party, drunk with success, condemned their chief opponents to death. Among these was Phocion: he died with the greatest composure, and left an injunction to his son, to preserve no remembrance of the wrongs which Athens had done to his father. As in the case of Socrates, the people soon saw their error; repentance however does not usually atone for political crimes, and the parallel between Phocion and Socrates holds good with regard to the evil times which followed their respective executions, showing public ingratitude to be the parent as well as the child of civil corruption. (Plutarch's *Life of Phocion;* Thirlwall's *Hist. of Greece.*)

PHOCIS (Φωκίς) was bounded on the south by the Corinthian Gulf, on the west by Doris and the Locri Ozolæ, on the north by the Locri Epicnemidii and Opuntii, and on the east by Bœotia. The territory of Phocis originally extended to the Eubœan channel, but was in later times entirely separated from the sea by Locris. Strabo says (ix., p. 416) that Phocis was divided into two parts by the range of Parnassos, which extends in a south-easterly direction through Phocis till it joins Mount Helicon on the borders of Bœotia. Parnassos and the mountains which separate Phocis from Locris form the upper valley of the river Cephissus, on the banks of which there is some fertile country, though in many parts the mountains approach very near both banks of the river. The southern part of Phocis is almost entirely covered with the mountains which branch off to the south from the huge mass of Parnassos, though there are a few fertile plains between these mountains, of which the largest is the celebrated Crissæan plain.

We know very little respecting the early inhabitants of Phocis. According to Pausanias (ii., 4, § 3; x., 1, § 1) the people derived their name from a king Phocus; and that the name is of considerable antiquity is evident from the Phocians being mentioned by Homer (*Il.*, ii. 517). Previous to the Persian invasion they appear to have been frequently engaged in hostilities with the Thessalians, and to have been successful in maintaining their independence. (Herod., viii. 27, 28.) Xerxes, at the instigation of the Thessalians, ravaged Phocis with fire and sword, and destroyed many of their cities. (Herod., viii. 32.)

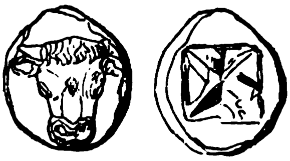
The Phocians had no political importance till after the battle of Leuctra: but shortly after that event, circumstances occurred which occasioned the celebrated Phocian or Sacred War, in which all the great states of Greece were more or less concerned. The immediate occasion of this war is said by Diodorus (xvi. 23) to have been an act of sacrilege committed by the Phocians in cultivating a part of the Crissæan plain, which had been doomed by a decree of the Amphictyons, in B.C. 585, to lie waste for ever. But whatever may have been the immediate, the real occasion of the war was the animosity between Thebes and Phocis, which had long prevailed under a show of peace. The Thebans used their influence in the Amphictyonic council to induce the Amphictyons to sentence the Phocians to pay a heavy fine to the god for the violation of the sacred land; and on their refusing to pay this fine, the council passed a decree that if the fine were not paid, the Phocians should forfeit their territory to the gods, which decree was in all probability intended to reduce the Phocians to the condition of the Helots in Laconica, subject to the jurisdiction of the temple of Delphi. In these alarming circumstances the Phocians were induced by Philomelus, who appears to have held some high office in the Phocian state, and was a man of great talent and energy, to make the bold attempt at seizing the city and temple of Delphi. This attempt was successful, and the Phocians obtained in the treasures deposited in the temple ample means for carrying on the war. This war, which lasted for ten years, was carried on with various success on both sides. The Thebans and almost all the northern states of Greece were opposed to the Phocians; and though the Athenians and Spartans were willing, in consequence of their fear of the power of Thebes, to afford assistance to the Phocians, the former were too much weakened by the Peloponnesian war, and the latter by the Theban victories and the formation of Messenia as an independent state, to render any effectual aid. But what the Phocians wanted in allies was compensated by mercenary troops; and it is difficult to say how long the struggle might have lasted, had not the Amphictyons called in the assistance of Philip of Macedon, who took possession of Delphi, and put an end to the war, B.C. 346. The Phocians were severely punished for their sacrilege; all their cities, with the exception of Abæ, were razed to the ground, and their inhabitants dispersed in villages not containing more than fifty inhabitants. Their two votes in the Amphictyonic council were taken away and given to Philip. (Paus., x., 3, § 1; Diod., xvi. 59; Æschin., *De Fals. Legat.*, p. 45.) Many of the towns however appear to have been rebuilt soon afterwards. [PHILIP, p. 74.]

The principal towns of Phocis were Delphi [DELPHI] and Elatea; the latter of which was situated on a small hill above the plain watered by the Cephissus. It was taken and burnt by the army of Xerxes (Herod., viii. 33), but was rebuilt soon afterwards, and became from its position the most important town in Phocis. It commanded the chief road which led from the north of Greece to Bœotia and Attica (Strab., ix., p. 424), and hence we read in Demosthenes (*De Corona*, p. 284) that the greatest alarm prevailed at Athens when intelligence was brought that Elatea was seized by Philip. The ruins are at the modern Elephta.

On the sea coast the first town we come to after leaving the Locri Ozolæ is Cirrha, situated at the head of the Crissæan Gulf (*Bay of Salona*) and at the mouth of the Pleistus. Cirrha was the port of Delphi, from which it was distant 60 stadia according to Pausanias (x. 37, § 4), and 80 according to Strabo (ix., p. 418). This town is frequently confounded with Crissa, which is mentioned as a separate place by Strabo, and said to have been situated between Delphi and Cirrha. The Crissæans were charged by the Delphians with undue exactions from the strangers who came to consult the Delphian oracle. The Amphictyons declared war against them, which, after lasting for ten years, ended in the destruction of Crissa, B.C. 585, the land of which was dedicated to the god. (Paus., x. 37, § 4.)

The next town to Cirrha on the coast was Anticyra, celebrated for its preparation of hellebore, which grew in the mountains above the town. (Strab., ix., p. 418; Paus., x. 36, § 3.) Next to Anticyra was Medeon, destroyed with the other Phocian towns after the termination of the Sacred War and never restored (Paus., x. 36, § 3); and after it the small town of Marathus (Strab., ix., p. 423), beyond which was the Pharygian promontory with a station for ships. The most easterly town in Phocis on the coast was Mychus. (Strabo, ix., p. 423.)

There are few towns of any importance inland, with the exception of Delphi and Elatea. North-east of Delphi was Lycorea, a place of great antiquity. It is said in the Parian Marble to have been the residence of Deucalion, and Strabo (ix. 418) speaks of it as more antient than Delphi. (Compare Paus., x. 32, § 6.) Above Lycorea was Tithorea or Neon, at the distance of 80 stadia from Delphi. (Paus., x. 32, § 6.) Its ruins are near the modern village of Velitza. Pausanias (x. 32, § 11) says that the oil of Tithorea was admirable for the composition of perfumed ointments. West of Tithorea, and at the foot of Parnassos, was the antient city of Lilæa, which is mentioned by Homer (*Il.*, ii. 523) as near the sources of the Cephissus. It was distant from Delphi 180 stadia across the Parnassos. (Paus., x. 33, § 1.) On the borders of Bœotia was the town of Ambysus or Ambyssus (Paus., x. 36, § 2; Strabo, ix. 423), which is not unfrequently mentioned in history. In the Macedonian war it was taken by Flamininus. (Liv., xxxii. 18.) Its ruins were discovered by Chandler near the modern village of Dystomo.



Coin of Phocis.

British Museum. Actual size.

PHOCY'LIDES, of Miletus, was a philosopher and poet, and flourished about B.C. 535. An admonitory poem (ποίημα νουθετικὸν) is attributed to this Phocylides; but it is uncertain whether it was written by him or by another of the same name in later times. The reader is referred, for a discussion of this question, to the first volume of the 'Bibliotheca Græca' of Fabricius.

There are several editions of Phocylides, both separate and along with Theognis and others. A convenient and correct edition of these Greek gnomic or sententious poets is that printed by Tauchnitz, Leipzig, 1819, which includes seven fragments of Phocylides, besides the above-mentioned poem.

PHŒNI'CE, PHŒNICIANS (Φοινίκη, Φοίνικες). Phœnice* proper, even in its most flourishing state, was a very small country. It extended along the eastern coast of the Mediterranean, from the town of Aradus and the river Eleutherus, on the north, to Mount Carmel, or Dora, on the south. (Ptolem., v. 15; Plin., *Hist. Nat.*, v. 13, 17; Joseph., *Apion*, ii. 9.) It was bounded on the east by the mountains Libanus and Antilibanus, from which numerous streams descended, which rendered the land exceedingly fertile. (Ammianus Marcell., xiv. 8.) The physical character of this country is more particularly described under SYRIA.

This short line of coast was covered with numerous towns, which were more or less celebrated for their arts and manufactures. The most southerly town of importance was Acco, called by the Greeks Acca, and subsequently Ptolemais (*St. Jean d'Acre*), which the Israelites did not conquer, though it was included in the division of the Holy Land made by Joshua. (*Judges*, i. 31.) In the time of Augustus (Strabo, xvi., p. 758) it was a large city; and under Claudius it became a Roman colony. (Plin., *Hist. Nat.*, v. 17.) The subsequent history and present state of this city are given under ACRE.

North of Acco was TYRE, the principal of the Phœnician cities, and north of Tyre, SIDON. Between Tyre and Sidon was Sarepta (*Sarphand*), which is mentioned in the history of Elijah (1 *Kings*, xvi. 9) under the name of Zarephath. (Compare *Obadiah*, v. 20; *Luke*, iv. 26; Joseph., *Antiqu.*, viii. 13, § 2.) About eight miles and a half north of Sidon was Berytus, a very antient town with a harbour. (Ptolem., v. 15; Strabo, xvi., p. 755; Joseph., *Bell. Jud.*, vii. 3, § 1; Ammian. Marcell., xiv. 8; Mela, i. 12.) It is supposed by some writers to be the same place as Berothai, which was taken by David. (2 *Sam.*, viii. 8.) Berytus was destroyed by Diodotus Tryphon (B.C. 140), but was rebuilt by Agrippa, who stationed there two legions. (Strabo, xvi., p. 756.) It also became a Roman colony under the name of Felix Julia. (Plin., *Hist. Nat.*, v. 17.) The modern town of Bairuth or Beirut is still a place of some importance. [BEIRUT.]

Twenty-four miles north of Berytus was Byblos, situated on rising ground, not far from the sea. It was celebrated for the worship of Adonis. (Strabo, xvi., p. 755; Plin., *Hist. Nat.*, v. 17; Mela, i. 12; Ptolem., v. 15.) Winer supposes (*Biblisches Realwörterbuch*, art. *Byblos*) that the town Gebal mentioned in the Old Testament (*Ezek.*, xxvii. 9; compare *Josh.*, xiii. 5) is the same place as Byblos. [BYBLUS.]

North of Byblos was Botrus; and beyond it Tripolis, which originally consisted of three distinct towns, founded respectively by Sidon, Tyre, and Aradus, and was used by the inhabitants of the different cities of Phœnice as a common place of meeting for deliberating on subjects of common importance. (Strabo, xvi. 754; Plin., v. 17; Diod. Sic., xvi. 41; Mela, i. 12.) North of Tripolis was Orthosias (Plin., *Hist. Nat.*, v. 17; Strabo, xvi., p. 753; 1 *Macc.*, xv. 37), and still farther north Aradus, a colony of Sidon, and the most important town in Phœnice after Tyre and Sidon, situated in an island of the same name, which is called Arvad in the Old Testament. (*Ez.*, xxvii. 8; *Gen.*, x. 18.) This island was at the mouth of the Eleutherus, and 20 stadia from the mainland. It was only seven stadia in circumference, but was crowded with houses. (Strabo, xvi. 753; Plin., v. 17; Mela, ii. 7.) Opposite to it on the mainland was the town of Antaradus.

The Phœnicians were a branch of the great Semitic or Aramæan family of nations, and originally dwelt either on the Red Sea or the Persian Gulf. (Herod., i. 2; vii. 89; Strabo, i., p. 42.) It is uncertain at what time they emigrated to the coast of the Mediterranean; but it must have been at a very early period, since Sidon was a great city in the time of Joshua (*Josh.*, xix. 28). The Phœnicians far surpassed all the other nations of antiquity in commercial enterprise. Their greatness as a commercial people was chiefly owing to their peculiar natural advantages. Their situation at the extremity of the Mediterranean enabled them to supply the western nations with the different commodities of the East, which were brought to Tyre by caravans from Arabia and Babylon; while their own country produced many of the most valuable articles of commerce in antient times. Off the coast the purple fish was caught which produced the most celebrated dye known to the antients, and the sand on the sea-shore was well adapted for the manufacture of glass. (Strabo, xi. 758; Plin., xxxvi. 65.) Mount Libanus supplied them with abundance of timber for ship-building, and the useful metals were obtained in the iron and copper mines near Sarepta. In the west they in all probability visited Britain [CASSITERIDES]; and on the north coast of Africa, in Spain, Sicily, and Malta, they planted numerous colonies, which they supplied with the produce of the East. Their settlements in Sicily and Africa became powerful states, and long opposed a formidable barrier to the Roman arms. [CARTHAGE.] By their alliance with the Jewish state in the time of Solomon, they were enabled to sail to Ophir in the south of Arabia, where they obtained the produce of India. (2 *Chron.*, viii. 17, 18; 1 *Kings*, ix. 27, 28.) Herodotus says that they circumnavigated Africa, but there appears considerable reason for doubting the truth of this account. [AFRICA, vol. i., p. 172.] It has been even maintained by some writers that they sailed to America. (Diod. Sic., v. 19.)

---

* Modern writers usually call the country Phœnicia, but this form is not once found in the antient writers, with the exception of a doubtful passage in Cicero. (*De Fin.*, iv. 20).

The Greeks attributed the invention of letters to the Phœnicians, and there can be little doubt that the Greek alphabet was derived from the Phœnician. They are also said to have invented arithmetic and many of the sciences; but the traditions on these subjects are too vague to enable us to come to any safe conclusion. There can be no doubt however that they attained to great perfection in the arts in very early times. The Tyrians supplied Solomon with all kinds of artificers to assist in the building of the temple at Jerusalem (2 *Chron.*, ii.), and the workmanship of the artists of Sidon was celebrated in the Greek towns of Asia Minor as early as the time of Homer. (*Il.*, xxii. 741; *Od.*, xv. 118.)

The Phœnician cities appear to have been originally independent of one another, and to have possessed for the most part a monarchical form of government. The oldest of these cities was Sidon (*Gen.*, x. 15), but Tyre became in later times the most important, and probably exercised some degree of authority over the other states. After the conquest of Samaria and Judæa, the Phœnicians became subject successively to the Assyrian, Babylonian, and Persian monarchies. In the wars between the Greeks and Persians, the Phœnicians formed the chief and most efficient part of the Persian navy. They afterwards formed part of the dominions of the Seleucidæ, and were eventually included in the Roman province of Syria.

The language of the Phœnicians and of the different colonies which they planted closely resembled the Hebrew and Aramaic. Even if we had no remains of the language we could have little doubt that such was the case; but Gesenius has satisfactorily shown, from numerous coins and inscriptions, the intimate connection between the Phœnician and the other languages of the Semitic nations. The letters of the Phœnician alphabet closely resemble those of the Samaritan. In addition to which it may be remarked, though no further proof is wanted, that Jerome represents (*Comment. ad Is.* vii. 19) the Phœnician language as allied to the Hebrew, and he says the same of the Punic, which however, he observes, was more remote from the mother tongue. (*Comment. ad Gen.* xxxvi. 24.) Augustin also makes the same remark respecting the Punic, which was spoken at Hippo in his time. For further information upon this subject the reader is referred to Gesenius's 'Paläographische Studien über Phönizische und Punische Schrift,' 4to., Leip., 1835, and 'Scripturæ Linguæque Phœniciæque Monumenta,' &c., 4to., Leip., 1837. Among the works written in the Phœnician language, the most celebrated is the history of the Phœnicians and Egyptians, in nine books, by Sanchoniathon, of which a Greek translation was made by Philo Byblius in the first half of the second century of the Christian æra. [SANCHONIATHON.]

PHŒNI'CIA. [PHŒNICE.]

PHŒNICIRCUS. [PIPRINÆ.]

PHŒNICOPHAINÆ. [PHŒNICOPHAUS.]

PHŒNICOPHA'US, M. Vieillot's name for a genus of birds founded on the *Malkohas*, or *Malcohas*. Levaillant appears to have been the first who proposed a separation of the form from the *Cuckoos*, and Mr. Swainson, who in his 'Synopsis' places it among the *Crotophaginæ*, or *Horn-Bill Cuckoos*, observes that the passage from the *Toucans* to the *Cuckoos* seems to be marked by such genera as *Phœnicophaus* or *Saurothera*, where the bill, as in the first, is either much larger and thicker than in the generality of *Cuckoos*, and is thus assimilated in shape to that of the *Toucan*, or as in *Saurothera*, where the edges become dentated.

The *Generic Character*, as restricted by Mr. Swainson, will be found in the article INDICATORINÆ.

Example, *Phœnicophaus Pyrrhocephalus*.

This appears to be the *Cuculus Pyrrocephalus* of Forster and the *Phœnicophaus leucogaster*, Desm.

In July, 1839, Mr. Fraser read to a meeting of the Zoological Society of London his description of a bird of this genus, *Phœnicophaus Cumingi*, belonging to Mr. Swainson's subdivision *Dasylophus*, forwarded by Hugh Cuming, Esq., corresponding member from Luzon. Mr. Fraser pointed out that it might at once be distinguished from all the known members of the family by the singular structure of the feathers of its crest and throat; the shafts of these feathers are expanded at their extremities into laminæ, which may be compared to the shavings of whalebone; and in this respect they resemble the crest of the Toucan, to which Mr. Gould, in his monograph, applies the name *Pteroglossus ulocomus*, which is the *Pt. Beauharnesii* of Wagler, but are not curled as in that species. The feathers above the nostrils, of the crest and chin, and along the middle of the throat, are grey at the base, have a decided white spot towards the middle, and are terminated by a broad expansion of the shaft, which is of a glossy black colour, with blue or greenish reflections. The external edge of this expanded portion of the shaft is minutely pectinated. The occiput and sides of the head are grey, passing into dirty white on the cheeks and sides of the throat; the hinder part and sides of the neck and the breast are of a deep chestnut colour; the back, wings, and tail are of a deep shining green colour; all the tail-feathers are broadly tipped with white; the vent, thighs, and under tail-coverts are dusky brown tinged with green; the bill is horn-colour; the feet olive. According to that indefatigable collector Mr. Cuming, this beautiful and interesting bird is named *Ansic En Bicol* in the Albay tongue. The eyes were red, and the pupil large and black. The length from beak to tail was eight inches and a half, and the measurement round the body five inches. Total length sixteen inches. (Fraser.) (*Zool. Proc.*, 1839.) In the same volume another species, from Malaya, *Phœnicophaus viridirostris* is described by Mr. Eyton—native name, see *Lahia*. The synonyms given are *Psittacula Malaccensis*, Kuhl—native name, *Tana; Bucco trimaculata*, Gray—native name, *Tanda;* and *Bucco versicolor*, Raff.—native name, *Tahoor*. *Phœnicophai tricolor*, Steph.—native name, *Kado besar; Chlorocephalus* (*Cuculus chlorocephalus*, Raffles—native name, see *Luhia*); *Crawfurdii*, Gray—native name, *Kada Kachie;* and *Javanicus*, Horsf.—native name, *Kada Apie*, are also referred to by Mr. Eyton as synonyms of *Anthreptes modesta* from Malaya—native name, *Chichap Nio*.

In Mr. G. R. Gray's arrangement the *Phœnicophainæ* consist of the genera *Phœnicophaus*, Vieill.; *Carpococcyx*, G. R. Gray; *Rhinortha*, Vig.; and *Taccocua*, Less.; and the six subfamilies of the *Cuculidæ* are *Indicatorinæ*, *Saurotherinæ*, *Centropinæ*, *Phœnicophainæ*, *Coccyzinæ*, and *Cuculinæ*.

PHŒNICOPTERI'NÆ, Mr. Swainson's name for his first subfamily of the *Anatidæ*, consisting of the genus *Phœnicopterus* only. The same position is given to the *Phœnicopterinæ* by Mr. G. R. Gray.

PHŒNICO'PTERUS. [FLAMINGO.]

PHŒNICO'RNIS, Mr. Swainson's name for a genus of *Ceblepyrinæ*, or *Caterpillar-Catchers*. [SHRIKES.]

PHŒNICU'RA. Mr. Swainson's name for the *Redstarts*. [SYLVIADÆ.]

PHŒNISO'MA, Mr. Swainson's name for a genus of *Fringillidæ;* and placed by him in the subfamily *Tanagrinæ*. [FRINGILLIDÆ; TANAGRINÆ.]

PHŒNIX (Φοῖνιξ), one of the most renowned of the fabulous monsters of antiquity, defined by the Arabians to be *maloúmo 'l-ismo, majnoúlo 'l-jismo* '(a creature) whose name is known, its body unknown.' (Richardson's *Arabic and Persian Dict.*) It is supposed by some persons to be mentioned in the Bible, *Job*, xxix. 18, and *Psalms*, xcii. 12. In the former passage כחול is translated in our version 'as the sand,' but by Bede, 'Sicut *Phœnix;*' in the other, כַּתָּמָר, which is rendered in our version 'like the palm tree,' is explained to mean the phœnix by Tertullian (*De Resurrect. Carnis*, sec. 13, p. 387). Omitting these two passages, which are rightly translated in our version, and therefore have no reference to the phœnix, the earliest author who mentions it is Hesiod (ap. Plut., *De Defectu Orac.*, cap. 11, ed. Tauchn.; and ap. Plin., *Hist. Nat.*, lib. vii., cap. 49), who merely says that it lives nine times as long as a crow. The first detailed description and history that we meet with is in Herodotus, whose words on that account deserve to be quoted at length. 'There is also,' says he, in his account of Egypt (lib. ii., cap. 73), 'another sacred bird, the name of which is the phœnix; I have not myself seen it except in a picture, for it seldom visits them, only (as the people of Heliopolis say) every five hundred years. And they say that he only comes when his sire dies. And he is, if he is like his picture, of size and shape as follows: part of his plumage is gold-coloured, and part crimson; and he is for the most part very like to the eagle in outline and bulk. And this bird, they say, devises as follows, but they say what is to me beyond belief: that setting out from Arabia, he brings his sire to the temple of the sun; that he covers him with myrrh, and buries him in the temple of the sun: and that he conveys him thus: first he forms an egg of myrrh as large as he is able to bear, and afterwards tries whether he can carry it; and when he has made the trial, upon this he hollows out the egg, and puts his sire into it, and covers with other myrrh that part of the egg where he had made the hole and put in his sire; and when his sire lies inside, the weight [of the egg] is the same [as it was before it was hollowed out], and having covered him up, he conveys him to Egypt into the temple of the sun. Such are the things which they say this bird performs.' Such is the story as told in Herodotus, and it is substantially the same as what was afterwards, though with various embellishments, repeated and believed for more than a thousand years. It would be tedious and useless to quote the words of each author who forms a link in the chain: it will be sufficient to mention that, between the times of Herodotus and Tacitus, the fable of the 'Phœnix' is told more or less fully and circumstantially by the following classical writers: Antiphanes (ἐν τοῖς 'Ομοπατρίοις, ap. Athen., *Deipnos*, lib. xiv., sec. 70, p. 655), Chæremon (ap. Tzetz., *Chil.*, v. 395), Lucan (*Phars.*, lib. vi., v. 680), Martial (*Epigr.*, v. 7), Mela (*De Situ Orb.*, lib. iii, cap. 8), Ovid (*Metam.*, lib. xv., v. 391, sq.; *Amor.*, lib. ii., el. 6, v. 54), Pliny (*Hist. Nat.*, lib. x., cap. 2; lib. xi, cap. 44; lib. xiii., cap. 9), Seneca (*Epist.*, 42, sec. 1), and Statius (*Silv.*, lib. ii., 4, 36; lib. iii., 2, 114). The passage in which Tacitus notices the Phœnix is very remarkable, and deserves to be quoted at length as being the most authentic account of it that has been preserved and also as showing that so cautious and accurate a man as he is always considered to be entertained no kind of doubt as to its real existence and its periodical appearance in Egypt. 'In the consulship of Paulus Fabius and Lucius Vitellius,' says he (in Murphy's translation, *Annal.*, lib. vi., cap. 28) A.U.C. 787, A.D. 34, 'the miraculous bird, known to the world by the name of the phœnix, after disappearing for a series of ages, revisited Egypt. A phenomenon so very extraordinary could not fail to produce abundance of curious speculation. The learning of Egypt was displayed, and Greece exhausted her ingenuity. The facts, about which there seems to be a concurrence of opinions, with other circumstances, in their nature doubtful, yet worthy of notice, will not be unwelcome to the reader. That the phœnix is sacred to the sun, and differs from the rest of the feathered species in the form of its head and the tincture of its plumage, are points settled by the naturalists. Of its longevity the accounts are various. The common persuasion is that it lives five hundred years' [Herodotus, Ovid, Seneca, and Mela, *locis cit.*; Philostratus (in *Vitâ Apollon. Tyan.*, iii., 49, ed. Olear., p. 134 and 135), Ælian (*Hist. Animal.*, lib. vi., cap. 58), Aurelius Victor (*De Cæsar.*, cap. 4, sec. 12; *Epit.*, cap. 4, sec. 10), Horapollo (in *Hieroglyph.*, No. 34, p. 41); St. Clement of Rome (*Epist. ad Corinth.*, cap. xxv., p. 98, ed. Jacobson), St. Cyril of Alexandria (*Catech.* xviii. 8)]; 'though by some writers the date is extended to one thousand four hundred and sixty-one.* The several æras when the phœnix has been seen are fixed by tradition. The first, we are told, was in the reign of Sesostris; the second, in that of Amasis; and in the period when Ptolemy, the third of the Macedonian race, was seated on the throne of Egypt, another phœnix directed its flight towards Heliopolis, attended by a group of various birds, all attracted by the novelty, and gazing with wonder at so beautiful an appearance. For the truth of this account we do not presume to answer. The facts lie too remote; and covered, as they are, with the mists of antiquity, all further argument is suspended. From the reign of Ptolemy to Tiberius, the intermediate space is not quite two hundred and fifty years. From that circumstance it has been inferred by many that the last phœnix was neither of the genuine kind nor came from the woods of Arabia. The instinctive qualities of the species were not observed to direct its motions. It is the genius, we are told, of the true phœnix, when its course of years is finished, and the approach of death is felt, to build a nest in its native clime, and there deposit the principles of life, from which a new progeny arises. The first care of the young bird, as soon as fledged, and able to trust to its wings, is to perform the obsequies of his father But this duty is not undertaken rashly. He collects a quantity of myrrh, and to try his strength, makes frequent excursions with a load on his back. When he has made his experiment through a long tract of air, and gains sufficient confidence in his own vigour, he takes up the body of his father, and flies with it to the altar of the sun, where he leaves it to be consumed in flames of fragrance. Such, adds Tacitus, 'is the account of this extraordinary bird. It has, no doubt, a mixture of fable; but that the phœnix, from time to time, appears in Egypt, seems to be a fact sufficiently ascertained.'

After the time of Tacitus the fable of the phœnix is repeated or alluded to by the following classical authors, besides those already referred to:—Achilles Tatius (*De Leuc. et Clit.*, lib. iii., cap. 25, p. 147, ed. Mitscherl.), Aristides (*Orat.*, tom. ii., p. 107, ed. Jebb, et ibi Scholiast.), Artemidorus (*Oneirocrit.*, lib. iv., cap. 49, p. 228, ed. Rigalt), Ausonius (*Eidyll.*, 18, v. 6, p. 535: and *Eidyll.*, 11, v. 16, p. 454, ed. Toll.), Claudian (*Eidyll.*, 1, 'De Phœnice;' in *Prim. Consul. Stilich.*, lib. ii., v. 414, sq.; *Epist.*, i. 'Ad Seren.,' v. 15), Dion Cassius (*Hist. Rom.*, lib. 58, cap. 27), Diogenes Laertius (*De Vit. Philosoph.*, lib. ix., cap. 11, secs., 9 and 79), Lampridius (in *Heliogab.*, cap. 23), Lucian (*Hermot.*, cap. 53: *Navig.*, cap 44; *De Morte Peregr.*, cap. 27), Oppian (*De Aucupio*, i. 28, ed. Schneid., p. 182), Photius (*Biblioth.*, cod. 126, p 305), and Solinus (*Polyhist.*, xxxiii. 11). Of these passages perhaps the only one curious enough to be particularly noticed is that in Lampridius, who tells us that Heliogabalus promised his guests a phœnix for supper: he was however obliged to be content with a dish of the tongues of phœnicopters (or flamingos).

But it is not only in heathen authors that this fable is to be found; it is mentioned and believed by the Jewish Rabbinical writers, and by the early fathers of the Christian church. Ezekiel, the Jewish tragic writer [vol. ix., p. 135, col. b], describes the phœnix in his 'Exagoge' (ap Euseb., *Præpar. Evangel.*, lib. ix., cap. 29, p. 446, ed. Colon., 1688); and Kimchi informs us (ap. Bochart, *Hieroz.*, part ii., lib. vi., cap. 5, p. 818) that in the passage of Job quoted above some of the Rabbis read חול, *the Phœnix*, instead of חול, *the sand*. The very words of several of these writers may be seen in Bochart (*loco cit.*); but the only Rabbinical addition to the story worth noticing is preserved by Rabbi Osaia in his 'Berescith Rabba,' cap. 19 (ap. Bochart, *loco cit.*), who says that the reason why the phœnix lives so long, and is in a manner exempt from death, is because it was the only animal that did not eat of the forbidden fruit in Paradise. A somewhat similar bird seems to have been known to the Arabians under the name of *Anka*. Mr. Lane, in the notes to his new translation of the 'Tales of a Thousand and One Nights' (ch. 20, note 22), tells us, on the authority of Kaswini, that the anka is the greatest of birds; that it carries off the elephant as the kite carries off the mouse: that, in consequence of its carrying off a bride, God, at the prayer of a prophet named Handhalah, banished it to an island in the circumambient ocean, unvisited by men, under the equinoctial line; that it lives one thousand and seven hundred years; and that when the young anka has grown up, if it be a female, the old female bird burns herself; and if a male, the old male bird does so.

Many of the early fathers believed the story so firmly that they did not hesitate to bring it forward as a proof of the resurrection; and that, not as an *argumentum ad hominem*, when disputing with heathens, but seriously, and in writings addressed to converts to Christianity. St. Clement is the first who uses this argument (*loco cit.*), in which he is followed by St. Cyril and Tertullian (*locis cit.*), and Epiphanius (*Ancor.*, sec. 84, p. 89). The passage in St. Cyril (which also contains two or three additional embellishments) will serve as a specimen. 'God knew men's unbelief,' says he (in Mr. Church's translation, Oxford, 1838), 'and provided for this purpose a bird called a phœnix. This bird, as Clement writes, and as many more relate, the only one of its race, going to the land of the Egyptians at revolutions of five hundred years, shows forth the resurrection; and this, not in desert places, lest the mystery which comes to pass should remain unknown, but in a notable city, that men might even handle what they disbelieve. For it makes itself a nest of frankincense and myrrh and other spices; and entering into this when its years are fulfilled, it evidently dies and moulders away. Then from the mouldering flesh of the dead a worm springs, and this worm, when grown large, is transformed into a bird; and do not disbelieve this, for thou seest the offspring of bees also fashioned thus out of worms, and from eggs which are most moist thou hast seen the wings and bones and sinews of birds issue. Afterwards this phœnix, becoming fledged and a perfect phœnix, as was the former one, soars up into the air such as it had died, showing forth to men a most evident resurrection from the dead. The phœnix indeed is a wondrous bird, yet is irrational, nor sings psalms to God; it flies abroad through the sky, but it knows not the only-begotten Son of God. Is then a resurrection from the dead given unto this irrational creature, which knows not its maker; and to us, who ascribe glory to God and keep His commandments, shall there no resurrection be granted?' The story is also mentioned at greater or less length by Alcimus Avitus (*De Orig. Animæ*, i. 14, sec. 3), St. Ambrose (*Hexaem.*, lib. v., cap. 23; *In Psalm* cxviii., *Serm.* 19), St. Augustin (*De Nat. et Orig. Animæ*, tom. vii., lib. iv., col. 1203; *Serm.*, 18, tom. x., col. 1308), Epiphanius (*Physiol.*, tom. ii., p. 203), Eusebius (*De Vitâ Constant.*, lib. iv., cap. 72), Isidorus Hispalensis (*Orig.*, lib. xii., cap. 7), Lactantius (*Carm. de Phœnice*), St. Gregory of Nazianzum (*Orat.*, 37, p. 598), and Ruffinus (*in Symb. Exposit.*, p. 548). Origen seems to doubt its truth (*Cont. Cels.*, lib. iv., cap. 98, p. 229), and Photius blames St. Clement for his credulity in mentioning it (*Biblioth.*, cod. 126, p. 305); but these two are (as far as the writer is aware) the only two of the antient authors who do not believe it. This however ought not to lessen the authority of the fathers on other matters, nor should it be made a subject of reproach against them that 'they were not proficients in a branch of knowledge which has been a peculiar study of modern times.' (See Mr. Newman's preface to Mr. Church's *Translation of St. Cyril*, Oxf., 1838.)

---

* Manilius (ap. Plin., *Hist. Nat.*, lib. x., cap. 2) says that it lived five hundred and nine years; Solinus, five hundred and forty; Martial, one thousand; Chæremon, seven thousand and six

It would be almost impossible to enumerate all the more modern authors who, during the middle ages, expressed their belief in the existence of the Phœnix, for the list would include almost all the writers on natural history, besides a great number of others. Perhaps the most curious circumstance relating to it is what is told us by Camden (*Britannia*, p. 783, ed. Lond., 1607), viz. that Pope Clement VIII. sent, in 1599, to Lord Tyrone, the chieftain of the Irish rebels, a Phœnix's feather. This was mentioned in his work only eight years after the event took place, but we are not informed how the Pope procured the feather, or what had become of it at the time when Camden wrote.* Patricius Junius (*Patrick Young*), in his note on the passage of St. Clement, published 1633, argues in favour of the existence of the Phœnix, and says, 'Malo cum Clemente, Tertulliano, Origene, &c., errare, quam Maximum' (i.e. Max. Mart. Lib. ad Petrum cont. Severi Dogmata) 'et ejus sequacium opinionem sequi.' Sir Thomas Browne, in his 'Vulgar Errors,' (of which the first edition was published in 1646), thinks it necessary to state at some length his reasons for disbelieving the existence of the Phœnx (book iii., ch. 12); and in 1552 he was attacked for this and other pieces of incredulity by Alexander Ross, in a work entitled 'Arcana Microcosmi;' or, 'The Hid Secrets of Man's Body discovered,' &c. With respect to the Phœnix, the writer is not surprised at its seldom making its appearance, its instinct teaching it to keep out of the way of the tyrant of the creation—man; 'for had Heliogabalus, that Roman glutton, met with him, he had devoured him, though there were no more in the world!' (*Arca. Micr.*, p. 202.) Alexander Ross, who was really a person of some sense and learning, was probably one of the last believers in the Phœnix, which is now given up entirely to the poets; indeed, since the appearance of the 'Rejected Addresses,' almost abandoned even by them.† Of modern writers, besides Bochart and Sir Thomas Browne, the following are best worth consulting:—Henrichsen, 'Commentatio de Phœnicis Fabulâ,' Havn., 1825, 1827, 8vo.; Martini's edition of Lactantii 'Carmen de Phœnice,' 8vo., Lunæb., 1825; Salmasius, 'Exercit. Plin.,' p. 385, seq.; Creuzer, 'Symbolik und Mythologie,' &c., vol. i., p. 438, sq.; Münter, 'Sinnbilder und Kunstvorstellungen der alten Christen,' 4to., Altona, 1825, p. 94, sq.; Métral, 'Le Phénix, ou l'Oiseau du Soleil,' Paris, 1824; from one or other of which works the writer, to avoid the appearance of pedantry and ostentation, freely and willingly confesses that all the above references have been taken, except *three;* and of those *three, two* were furnished him by a friend.

PHŒNIX, a southern constellation of Bayer, which may be best described as close to (but farther from the south pole than) the bright star in Eridanus (Achernar). Its principal stars are as follows:—

ε	1938 C	5	4

PHŒNIX, a genus of palms, which has been so named from one of its species, the date-tree, having been called so by the Greeks: this name is thought by some to be derived from Phœnicia, because dates were procured from thence. The genus is common in India and in the north of Africa, and one of the species grows in Arabia, the lower parts of Persia, and along the Euphrates to Syria. The genus is characterised by having flowers diœcious, sessile, in a branched spadix, supported by a simple spathe; calyx urceolate, 3-toothed; corol 3-petalled; stamens 6 or 3; filaments very short, almost wanting; anthers linear; (female) calyx urceolate, 3-toothed; corol 3-petalled, with the petals convolute; pistil with three ovaries, distinct from each other, of which one only ripens; stigmas hooked; drupe one-seeded; seeds marked on one side with a longitudinal furrow; albumen reticulate; embryo in the back of the seed; palms with [illegible]ms of a moderate height and ringed, or marked with the seams of the fallen leaves; fronds or leaves pinnate; pinnæ or leaflets linear, with the spadix bursting among the leaves, surrounded with an almost woody two-edged sheath; flowers yellowish-white; fruit soft, edible, of a reddish yellow colour.

Phœnix dactylifera, or the date-tree, is one of the best known and probably the earliest known of the palms, and though belonging to a family which abounds and flourishes most in tropical regions, itself attains perfection only in comparatively high latitudes. It is no doubt the species to which the name Palma was originally applied, as we may infer from its being common in Syria, Arabia, the lower parts of Persia, as well as Egypt and the north of Africa, whence it has been introduced into the south of Europe, and cultivated in a few places, not only as a curiosity, but on account of its leaves, which are sold twice in the year, in spring for Palm Sunday, and in September for the Jewish Passover; and also, from the name not being applicable to the other species known to the antients, as it is considered that the bunches of dates were likened to the fingers of the hand, as appears from the present specific name, *dactylifera*, from the Greek *dactylus*, a finger. It is the palm-tree of Scripture, and was emblematic of Judæa, as we see in coins with the inscription of *Judæa capta*. It is found in oases in the desert, and round Palmyra, which is supposed to have been named from its presence. This appears indeed to be only a translation of the Oriental name, which is Tadmor, supposed to be a corruption of Tamar (from *tamr*, a date), a city built in the desert by Solomon. The date-tree is therefore a subject of classical as well as of scriptural interest, besides its fruit forming a large portion of the food of a great part of the Arab race, and also a considerable article of commerce.

---

* It must be the fellow to this feather that Beckford saw in the Escurial, and which was said to come from the wing of the Archangel Gabriel. He describes it (*Letters from Spain*, let. xi.) as 'the most glorious specimen of plumage ever beheld in terrestrial regions, full three feet long, and of a blushing hue, more soft and delicate than that of the loveliest rose.'

† The writer wishes it to be recorded for the information of posterity, that since writing the above sentence, he has found at Oxford a very learned scholar who, at this very time (June, 1840), seriously believes in the existence of the phœnix.

The date-palm being diœcious, that is, the stamens and pistils, or the male and female parts being not only in different flowers, but even on different plants, the crops entirely fail, or the fruit is worthless and unfit for food, if fertilization is in any way prevented. To ensure this, the Arabs have long been in the habit of hanging the clusters of male flowers on the trees which bear only female ones, and therefore the date-tree is one of those which led to a knowledge of the sexes of plants.

The extensive importance of the date-tree is, says Dr. Clarke, one of the most curious subjects to which a traveller can direct his attention. A considerable part of the inhabitants of Egypt, Arabia, and Persia subsist almost entirely on its fruit. They make a conserve of it with sugar, and even grind the hard stones in their hand-mills for their camels. In Barbary they form handsome beads for paternosters of these stones. From the leaves they make couches, baskets, bags, mats, brushes, and fly-traps; the trunk is split and used in small buildings, also for fences to gardens, and the stalks of the leaves for making cages for their poultry. The threads of the web-like integument at the bases of the leaves are twisted into ropes, which are employed in rigging small vessels. The sap is obtained by cutting off the head of the palm and scooping out a hollow in the top of the stem, where, in ascending, it lodges itself. Three or four quarts of sap may be obtained daily from a single palm, for ten days or a fortnight, after which the quantity lessens, until, at the end of six weeks or two months, the stem is exhausted, becomes dry, and is used for firewood. This liquor is sweetish when first collected, and may be drunk as a mild beverage, but fermentation soon takes place, and a spirit is produced, which is distilled, and forms one of the kinds of aruk (arrack), or spirit of Eastern countries. Such being the importance and multiplied uses of the date-tree, it is not surprising that in an arid and barren country it should form so prominent a subject of allusion and description in the works of Arab authors, and that it should be said to have 300 names in their language. Many of these are however applied to different parts of the plant, as well as to these at different ages.

Phœnix sylvestris is a species common in the arid parts of India, and there commonly called *khujjoor* by the natives, and the date-tree by Europeans, which it resembles in appearance. In its parts of fructification it is like the following species, but differs in growing to be a tree, with a tall pretty thick trunk and large yellowish or reddish fruit. It yields tarri, or palm wine, commonly called toddy. The mode of obtaining this is by removing the lower leaves and their sheaths, and cutting a notch into the centre of the tree near the top, from which the liquor issu[illegible] and is conducted by a small channel, made by a bit o[illegible]he palmyra-tree leaf, into a pot suspended to receive it. This juice is either drank fresh from the tree, or boiled down into sugar, or fermented for distillation, when it gives out a large portion of spirit, often called *paria aruk*. Mats and baskets are made of the leaves.

Sugar has always been made from this species, and accounts of it have been given by Drs. Roxburgh and Buchanan Hamilton. Date-sugar is not so much esteemed in India as that of the cane, and sells for about one-fourth less. It has been imported in considerable quantities into this country of late, but is not distinguished from the cane sugar. Dr. Roxburgh calculated, forty years ago, that about 100,000lbs. were made annually in all Bengal. At the age of seven or ten years, when the trunk of the tree is about four feet high, it begins to yield juice, and continues productive for twenty or twenty-five years. The juice is extracted during the months of November, December, January, and February, during which period each tree is reckoned to yield from 120 to 240 pints of juice, averaging 180 pints. Every twelve pints or pounds is boiled down to one of goor or jagari, and four of goor yield one of good sugar in powder, so that the average produce of each tree is about seven or eight pounds of sugar annually.

P. farinifera is a dwarf species of this genus, which is a native of dry ground or sandy hills, not far from the sea on the Coromandel coast. It flowers in January and February, and the fruit ripens in May. The leaflets are wrought into mats for sleeping on, and the common petioles are split into three or four, and used for making baskets. The small trunk is generally about fifteen or eighteen inches long, and about six in diameter. It encloses in its substance a large quantity of farinaceous substance, which the natives use for food in times of scarcity. To procure this meal, the small trunk is split into six or eight pieces, and dried and beaten in wooden mortars till the farinaceous part is detached from the fibres; it is then sifted, to separate them: the meal is then fit for use. The only further preparation which this meal undergoes is the boiling it into a thick gruel, or canji. It seems to possess less nourishment than common sago, which is obtained in a similar manner from another palm, and is less palatable when boiled, but it has saved many lives in times of scarcity.

PHŒTHORNIS. [TROCHILIDÆ.]

PHOLADA'RIA, Lamarck's name for a family belonging to the division of *Dimyarian Conchifers*, which he has termed *Crassipèdes*, and consisting of the genera *Pholas* and *Gastrochæna*; but M. Deshayes, in the last edition of the *Animaux sans Vertèbres*, remarks that this family can no longer remain in the same state as that which Lamarck assigned to it. The *Gastrochænæ*, he observes, are, as he had already stated, true *Fistulanæ*, and if either of the genera, *Gastrochæna*, or *Pholas*, be elected, the other must disappear. [GASTROCHÆNA.] He suggests that the genus *Pholas* alone should remain, unless the evident relations which connect it with *Teredo* and *Teredina* should render it necessary to unite all three genera into one natural family. [PHOLAS.]

PHOLADIDÆA. [PHOLAS, p. 109.]

PHOLADOM'YA. 'Qu'est-ce que le genre Pholadomie de quelques auteurs Anglois? C'est ce que nous ignorons; il paroît qu'il est établi avec une coquille fossile cunéiforme, très-large et très-bâillante en avant.' We will endeavour to answer the question thus put by M. de Blainville in his 'Malacologie.'

The genus *Pholadomya* is a most interesting form, for the knowledge of which we are indebted to Mr. G. B. Sowerby, who described it from a recent species brought from the island of Tortola by Mr. Nicholson, and in the possession of Mrs. Mawe, from whom it passed into Mr. Broderip's collection, and consequently is now in the British Museum.

The discovery of this recent species led at once to the more perfect knowledge of several fossils, whose genus, as Mr. Sowerby observes, in his *Genera* (No. xix.), was before exceedingly doubtful, insomuch that from a consideration of their external appearance alone, authors had been induced to place them in several genera, to none of which they really belonged; and he refers to Sowerby's *Mineral Conchology*, t. 197, 225, 226, 227, 299, and 327, where several of the species are figured under the names *Cardita? producta*, *obtusa*, *lyrata*, *deltoidea*, and *margaritacea*; and *Lutraria lyrata*, *ovalis*, *ambigua*, and *angustata*. These occur in several rocks of the oolitic series, particularly the cornbrash, inferior oolite, and fullers' earth; as well as in the lias, the London clay, and the Sutherland coal-field; also in the dark-coloured clay at Alum Bay.

Generic Character.—*Shell* very thin, rather hyaline, transverse, ventricose; inside pearly; posterior side short, sometimes very short, rounded; anterior side more or less elongated, gaping; upper edge also gaping a little. Hinge with a small, rather elongated, triangular pit, and a marginal lamina in each valve, to the outer part of which is attached the rather short external ligament. Muscular impressions two: these, as well as the muscular impression of the mantle, in which there is a large sinus, are indistinct. (G. B. Sowerby.)

The same zoologist remarks that this shell is the only instance known to him in which the umbones are so approximated as to be worn through by the natural action of the animal in opening and closing its valves. He further observes that the general aspect of this shell is between that of *Pholas* and *Anatina* of Lamarck, but most of the fossil species have been arranged as *Lutrariæ*. 'We have called it,' says Mr. G. B. Sowerby, '*Pholadomya* with reference to its resemblance to shells of two Linnean genera, the *Pholades* and *Myæ*. It is related to *Panopæa* in the characters of the hinge, but may be distinguished from that genus by its thin, semitransparent, pearly shell; from *Pholas* and *Anatina*, by its external ligament, and its want of external and internal accessory valves; and lastly, from the Lamarckian *Myæ*, by not having the unequal teeth of that genus.'

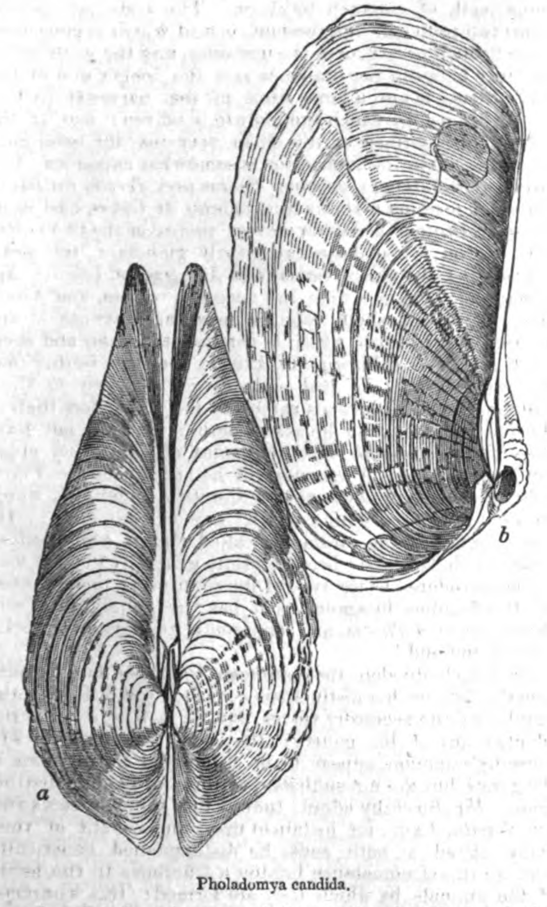
M. Deshayes, with his usual acuteness, saw at once the value of Mr. G. B. Sowerby's characters, and incorporated the genus *Pholadomya* in the new edition of Lamarck's *Animaux sans Vertèbres*, placing the form between *Solecurtus* of De Blainville and *Panopæa*.

But since the publication of the observations of the zoologists above given, Mr. Samuel Stutchbury has favoured us with a sight of the animal of the only recent species known—that on which Mr. G. B. Sowerby founded his generic description of the shell. This valuable specimen is now in the hands of Professor Owen, to whom we are indebted for the following description.

Animal of Pholadomya. '*Pholadomya* presents all the family characters of the *Inclusa* or *Enfermês*, but differs generically from all those, the organization of which has hitherto been described, by the presence of a fourth aperture leading to the interior of the mantle, that is to say, besides the linear slit for the protrusion of the narrow foot at the anterior part of the ventral aspect of the mantle and the two siphonic tubular passages, there is, at the under or ventral part of the base of the united siphons, a small round aperture, which is continued upon a truncated pyramidal papilla projecting into the pallial cavity, forming a valvular obstruction to the exit of fluids, but admitting their entry. This doubtless relates to some curious and peculiar feature in the œconomy of the mollusk: the foot is compressed, ½ inch long, 3 lines broad; the siphonic tube 2 inches long, ½ inch in diameter, bifid at the extremity; the labial appendages short; the two *branchiæ* of each side conjoined, and those of the right united to those of the left side along their posterior fourth. More of the anatomy I have not at present worked out; but there is enough, I think, here stated to serve as an answer to M. de Blainville's question.'

Example, *Pholadomya candida* (G. B. Sowerby).

Description.—Shell transversely oblong, very short posteriorly, rounded; median part marked with divaricated, decussate striæ, which are decurrent from the umbo; anteriorly elongated, subquadrate. (G. B. S.)



Pholadomya candida.

a, valves shut, the umbones towards the spectator; *b*, inside view of valve, showing the impressions and the umbo worn through.

Locality.—Marine, and, most probably, in deep water. The specimen from which Mr. Sowerby characterised the genus was thrown upon the beach at Tortola after a hurricane.

M. Deshayes, in his Tables, makes the number of living species one, and that of the fossil species (tertiary) the same. In the last edition of the *Animaux sans Vertèbres*, he records but three fossil species—*Pholadomyæ obtusa*, Sow.; *angulifera*, Desh.; and *producta*, Sow.; the first being *Cardita obtusa*, 'Min. Con.;' the second *Mya angulifera*; and the third *Cardita ? producta*, and *Pholadomya producta* of the same work. Our catalogues however contain numerous species. Thus we have, for example, *Pholadomya Murchisoni*, from the Inverbrora coal-pits and beds overlying coal upon the shore (Murchison 'On the Coal-field of Brora in Sutherlandshire,' &c., *Geol. Trans.*, vol. ii., 2nd series); *Pholadomya margaritacea*, from the arenaceous limestone or sandstone of Bognor, and another marked with an asterisk, indicating that it was either not in the possession of the author or not examined by him, from the Shanklin sand (Mantell, 'Tabular Arrangement of the Organic Remains of the County of Sussex,' *Geol. Trans.*, vol. iii., 2nd series); *Pholadomyæ decussata, Murchisoni, ovalis, producta, nana, deltoïdea, simplex, obsoleta, acuticostata*, and *obliquata*, from the Speeton clay, cornbrash, Bath oolite, calcareous grit, Kelloway's rock, and Oxford clay, &c. (Phillips, *Description of the Strata of the Yorkshire Coast*); *Pholadomyæ ambigua* from the lias, an unnamed species from the inferior oolite, *lyrata* from the fuller's earth, and *producta* and *lyrata* from the cornbrash (Lonsdale, 'On the Oolitic District of Bath,' *Geol. Trans.*, vol. iii., 2nd series); and *Pholadomya deltoïdea*, from the Oxford oolite, and other unnamed species from the gault and lower green-sand. (Fitton, 'On the Strata below the Chalk,' *Geol. Trans.*, vol. iv., 2nd series).

PHOLÆO'BIUS, Dr. Leach's name for a part of the genus *Saxicava* of authors. [LITHOPHAGIDÆ, vol. xiv., p. 50.]

PHOLARITE—*Hydrated Silicate of Alumina.* This substance occurs in small pearly scales, which are usually convex. These are white, soft, and friable, and they adhere to the tongue.

This substance occurs in the department of Allier in France, in the coal formation of Fins.

PHOLAS, a name given by Linnæus to a genus of conchifers, placed by Lamarck in his family *Pholadaria*. [PHOLADARIA.]

Generic Character.—Animal more or less thick and elongated, rarely shortened; mantle reflected on the dorsal part, for the purpose of tying together the valves and the accessory pieces; anterior aperture rather small; foot short, oblong, and flattened; siphons often elongated and united into a single, very extensible, and dilatable tube; mouth small, with very small labial appendages; branchiæ elongated, narrow, slightly unequal on each side, united on the same line nearly throughout their length, and prolonged even into the siphon.

Shell delicate, milky white, rather transparent, covered sometimes with a thin epidermis, oval, elongated, inequilateral, gaping posteriorly, and especially at the antero-inferior part; umbones hidden by a callosity; hinge toothless, ligament doubtful?;* a flat, recurved, spoon-shaped process enlarged at its extremity, elevating itself within each valve below the umbo; muscular impressions very distant, the posterior one large, oblong, elongated, always very visible, the anterior one small, rounded, but little distinct, both more or less approximated to the edge, particularly the anterior edge, of the shell, and joined by a pallial impression, which is long, narrow, and deeply excavated backwards.

Many accessory pieces or none? sometimes a calcareous tube enveloping all the parts, but leaving an aperture backwards. (Rang.)

M. Rang remarks that if the species which compose the genus *Pholas* were better known, they might be divided into many well characterised groups according to the number and disposition of the accessory pieces, which vary considerably; but unfortunately these accessory pieces are well known in a small number of species only. Besides, he observes, the genus is so imperfectly ascertained, although found in great abundance on the coasts of France, that naturalists are not yet agreed as to the number of mus-

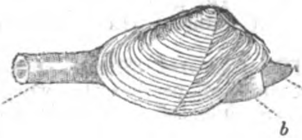
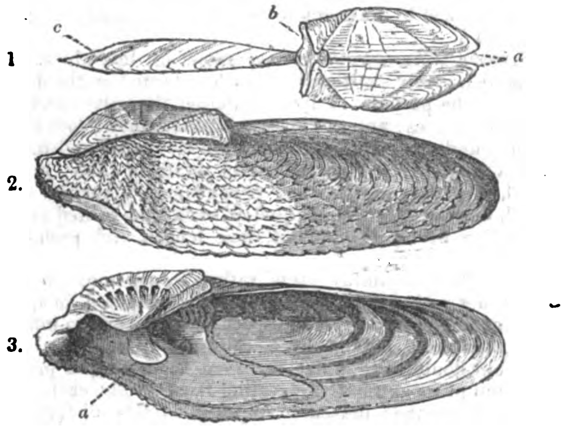
Pholas Dactylus (animal and shell); the lower or ventral parts are presented to the spectator.
a, mantle; *b*, foot; *c*, tube; *dd*, shell.



Animal of a Pholas (Julan—Pholas clavata? Lam.) from Adanson—side view.
a, tube; *b*, mantle; *c*, foot.



Shell of Pholas Dactylus.

1, Accessory valves: *a*, anterior pair; *b*, central piece; *c*. posterior piece. 2, Exterior view of shell, side view. 3, Internal view of valve: *a*, Spoon-shaped process.

cular impressions. Lamarck places the *Pholades* among the *Dimyaria*, and M. de Blainville sees but a single muscular impression: but M. Rang, speaking for himself, says that he has no doubt that these shells have two muscular impressions, which he has positively traced in *Pholas costata*, in following the pallial impression from its departure from the posterior muscular impression, which is always sufficiently evident, to the point where the former terminates anteriorly. There a small irregularly rounded impression may be very well distinguished. It has, continues M. Rang, been equally observed by M. Charles des Moulins in the same species, but science owes to that naturalist an observation relative to the *Pholades* perhaps even more important; it is, that these shells sometimes are seen accompanied by a calcareous tube, applied, like that of the *Gastrochænæ*, to the internal wall of the cavity which they inhabit. M. Rang had not been able to verify this fact in relation to living species; but M. des Moulins showed him several fossils from Mérignac, in which he completely recognised this important character, which more firmly establishes the generally admitted relationship between the *Pholades*, the *Teredinæ*, and the *Fistulanæ*. M. Rang further remarks that there are some species of *Pholades* which seem to lead to *Teredo*. These shells inhabit stones, madrepores, wood, and sometimes mud or sand (vase). When the reflux of the sea leaves them, and the animals are disquieted, they eject through their siphon to a considerable distance the water contained in their mantle, and which bathes the gills. (*Manuel de l'Histoire Naturelle des Mollusques.*)

'We believe,' says Mr. G. Sowerby, 'that all the shells of this genus are furnished with a greater or less number of accessory valves, which appear to be caused by the deposition of shelly matter (within the epidermis, and connected with the valves by that membrane), wherever such valves were necessary for the security of the inmate; they are consequently very various in form, and placed in different situations in the different species, though in most cases they are placed near the hinge, and have ever been considered to be substitutes (in these shells) for the permanent ligament of other bivalves: we must, for the present, withhold our assent from this opinion, because, on account of the situation in which they live, the animals inhabiting these shells can have very little occasion to open their valves. Whether or not there is any permanent ligament in this genus, as we have never observed the animal alive, we cannot undertake to determine: Turton says it has none; Lamarck, on the contrary, speaks of the accessory valves covering and hiding the ligament. As far as we can form an opinion from dried specimens, we cannot consider the substance to which these valves are attached as the ligament, but as part of the adductor muscle; nevertheless we think we can in some species perceive a very small internal ligament, attached to two unequally sized small curved teeth (one in each valve), placed in the same situation as the hinge teeth of common bivalves. The adductor muscle forms two principal impressions, one of which is placed on the reflected margin, over the umbones, and the other about half-way between the umbones and the longer end of the shell: there is also a large sinus in that narrower part of its impression by which the mantle is affixed; and at the angle that is formed by this sinus, very near the basal margin of the shell, the impression is somewhat expanded. The principal differences between *Pholas* and *Teredo* consist in the latter forming a shelly tube behind its valves, and in its being destitute of accessory valves; moreover the two valves of this latter, when closed, are nearly globular: the same characters distinguish *Pholas* from *Xylotrya* of Leach: *Xylophaga* of Turton, which has accessory valves, and which does not form a shelly tube, is however destitute of the internal curved tooth, which is common to *Pholas* and several *Tubicolées*.' (*Genera*, No. xxiii.) The same author (*loc. cit.*) remarks that he had endeavoured formerly to show that *Gastrochæna* belongs rather to the *Tubicolées* than to the *Pholadaires*; and he asks whether it would not have been more consistent with the rules of association apparently entertained by Lamarck, if he had united the *Petricolæ*, *Venerirupes*, and other terebrating conchifera, which do not form a shelly tube open at one or both ends? He also inquires if the commonly called *Pholas papyracea* (a shell which had lately become pretty generally known) may not be considered as the type of the connecting link between the two families, inasmuch as it has the general form and characters of a *Pholas*, and apparently commences a shelly tube at one end?

Dr. Leach divided the Linnæan *Pholades* into several genera; but as his distinctions consisted principally in the number of the accessory valves, Mr. G. B. Sowerby has not adopted any of his genera: they may, according to Mr. Sowerby's opinion, appear to be calculated for divisions of the genus, but are not sufficiently strong for generic distinctions. Mr. Sowerby admits indeed that some species (*Pholas clavata*, Lam., for instance) may, on account of their being closed at both ends, be distinguished generically, because this circumstance implies a difference in the habits of the animals by which they are formed: this character therefore, he remarks, has been seized by Dr. Leach, and upon it the doctor founded his genus *Martesia*, an example which Mr. Sowerby says he should have been induced to have followed, had he been convinced of its necessity. The same acute and experienced naturalist, upon the occasion of describing several new species of *Pholas* from the collection formed by the zealous Hugh Cuming, chiefly on the western coast of South America and among the islands of the South Pacific Ocean, prefaces his descriptions with the following admonition, which is well worthy of the attention of those who are interested in this branch of natural history:—

'The utmost caution is necessary in the examination and description of the various sorts of *Pholades*, on account of the extraordinary difference in the form of the same species in different stages of growth. The addition of accessory valves also, as they increase in age, must be carefully observed, in order to guard against too implicit a confidence in their number and form; and though I might be considered guilty of asserting a truism by stating that the difference in size of different individuals of the same species may, and sometimes does, mislead the tyro in the science of malacology—lest such difference should mislead the adept also, let him too proceed cautiously; and where he finds a fully grown shell of half an inch in length agreeing perfectly in proportions and characters with another of two inches long, let him not conclude that it is a distinct species; but if he can find no other difference except that which exists in their dimensions, let him consider the one a giant, the other a dwarf. Let it be remembered that among the *Cypræœ* it is not uncommon to observe young shells of three inches in length, and fully grown ones of the same sort only one inch in length; likewise of the well-known British *Pholades*, there are individuals quite in a young state of two inches in length, and perfectly formed shells of the same species not more than half an inch long. For instance in demonstration, I need only refer to the *Pholas papyraceus*, so abundant at Torquay, of which the young shells have been considered by many as a distinct species, and have been named by Dr. Turton *Pholas lamellosus*. This varies in size exceedingly, so that it may be obtained both in an incomplete and young state, and in a fully grown condition from half an inch to nearly two inches in length. The circumstance of its having rarely occurred in an intermediate state of growth, when the anterior opening is only partly closed, and the accessory valves only partly formed, led Dr. Turton and others to persist in regarding the young and old as two distinct species. Other similar instances will be shown in the course of the present concise account of some hitherto undescribed species of the same genus brought to England by Mr. Cuming.' (*Zool. Proc.*, 1834.)

Before we proceed any further, it becomes necessary to notice the genus *Jouannetia* of M. Ch. des Moulins, which is thus characterised:—

Animal unknown, but having, certainly, the characters of the family.

Shell spherical, cuneiform, equivalve, inequilateral, hardly gaping posteriorly, but widely open anteriorly; valves solid, short, curved, pointed below, striated obliquely, the striæ converging towards a median furrow; umbones but little distinct, with accessory pieces soldered over them; a very large, smooth, delicate, fragile scutcheon enveloping, with age, all the anterior part, formed of two rather unequal halves, fitting (s'emboîtant) one in the other, each soldered by one of their edges to one of the valves, and closing in this manner the anterior gape of the shell; no ligament nor hinge (engrenage); a setiform vertical appendage proceeding from the umbo, soldered to the interior of each valve, and occupying a third of its height; muscular impressions still unknown; pallial impression very strong, and deeply excavated backwards. Accessory pieces, but soldered; no enveloping calcareous tube, the large scutcheon occupying its place.

M. Rang speaks highly of the discovery of this genus by M. des Moulins, and having studied it with that naturalist, he pronounces it to be very distinct from the *Pholades*, and its place to be clearly fixed betweeen them and the *Teredines*, to which it leads so naturally by its valves. *Jouannetia*, he observes, has no enveloping calcareous tube, as sometimes happens to the *Pholades*, &c.; and though only one species is yet known (*Jouannetia semicaudata*, fossil, from the faluns of Mérignac, in the interior of madrepores, &c.), he does not think that a similar tube ever exists, if the amplitude and disposition of the scutcheon, which appears to him to take its place, is a generic character.

M. Deshayes, in the last edition of the 'Animaux sans Vertèbres,' does not think quite so highly of the genus *Jouannetia*, as we shall presently see. With regard to the accessory pieces of the *Pholades*, he considers that they are no other than vestiges of the complete tube of the *Teredines;* and this opinion, he observes, may rest upon the fact that those pieces are larger in proportion as the shell is more gaping posteriorly, and the external parts of the animal of greater size; so the shell of the *Teredines* being able to cover only a very small part of the animal, that defect is supplied by a great tube: on the contrary, in proportion as the shell of the *Pholades* is better closed, the number and size of the accessory pieces diminish. M. Deshayes then goes on to remark that, according to Lamarck, these pieces cover the ligament which is external; but M. Deshayes is convinced, both from the observations of Poli and his own, that the *Pholades* have no true ligament; and the same is the case with the *Teredines*. A part of the anterior muscle is inserted on the cardinal callosities, and occupies the place of the ligament. A posterior expansion of the mantle glides between these callosities, penetrates into the porous tissue placed below the callosities, and forms externally a fleshy surface more or less great, on which the posterior pieces are fixed. With regard to the internal appendages springing from the umbones, and which have somewhat the form of little spoons, they are buried in the thickness of the animal, and embrace in their concavity a part of the liver, the heart, and the intestine. M. Deshayes dismisses the genera *Xylophaga* and *Jouannetia* very shortly; the first he rejects as useless, nor can he allow that the last has more just claims to admission. If, he observes, genera so slightly characterised as these are were to be adopted, there would be as good reason for making a particular genus of each of the speces of *Pholas*.

Mr. Swainson makes the *Pholidæ* the first family of his tribe *Macrotrachiæ*, and thus characterises that family:—

'Shell bivalve, sedentary, generally perforating, opening at one or both ends; the valves often prolonged into a shelly tube, sometimes of great length, representing the *Tubulibranchia*.'

Under this family he assembles several forms, and makes it consist of the following genera and subgenera:—

1, *Aspergillum;* including the subgenera *Aspergillum*, *Clavagella*, and *Fistulana*.

2, *Gastrochina* (*Gastrochæna*), Lam.

3, *Pholadomya*, Sow.

4, *Pholas*, Linn., with the subgenera *Pholas*, Linn., *Pholidæa*, Leach, *Martesia*, Leach, and *Xylophaga*, Sow.; and

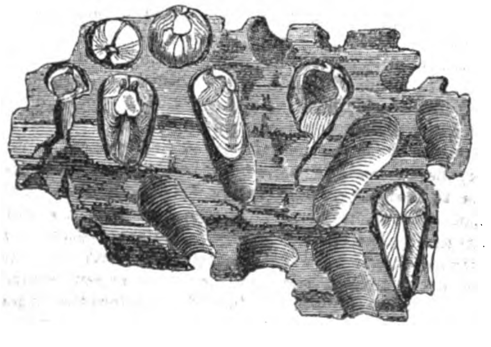
5, *Teredo*, Linn., with the subgenera *Teredo*, Linn., and *Teredina*. (*Malacology*, 1840.)

Locality, Habits, Organization, &c. of the genus *Pholas*.—The geographical distribution of the *Pholades* is very wide, and their habit of boring hard substances, such as indurated mud or clay, wood, and stone, renders them, as well as other terebrating testaceans, an object of anxious interest to those who construct submarine works. The Breakwater at Plymouth was soon attacked by the *Pholades*, and in Dr. Goodall's fine collection, now dispersed by the hammer, there was a specimen from the Breakwater perforated by these testaceans. Wood is also attacked by this genus, and submarine piles are consequently exposed to their ravages. To counteract their operations in the latter substance, nails closely driven into the submerged part of the timber, as in the piles which support the pier at Southampton, seem to be the best safeguard hitherto applied. When unmolested, the young *Pholades* excavate burrows in the substance which chance has opposed to them, or to which choice—for it is not improbable that the young shell-fish may in some cases have the faculty of making the selection of the material in which it is to pass the whole of its life—has directed it.

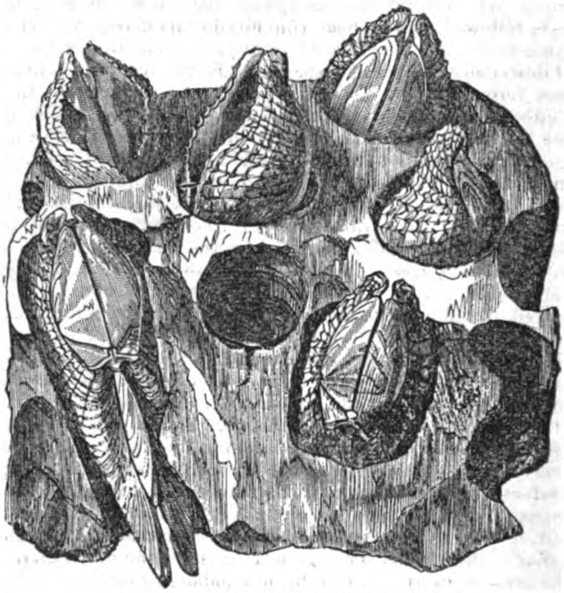
The mode in which this operation of boring is conducted is not quite satisfactorily accounted for; but the better opinion seems to be that in this, as in other excavating testaceans, the currents of water produced by the vibratile cilia of the animal, as noticed by Mr. Garner, are the principal agents. [LITHOPHAGIDÆ: see also CLAVAGELLA and GASTROCHÆNA.] Mr. G. B. Sowerby, in his description of *Pholas acuminata*, found by Mr. Cuming at Panamà in limestone at low water, notices one specimen in that gentleman's collection, as demonstrating a fact of considerable importance to geologists: it is in argillaceous limestone, very much resembling lias, and, in forming the cavities in which it resides, it has, by such chemical process as, in Mr. Sowerby's opinion, frequently takes place, absorbed a much greater quantity of the rock than could be retained or converted; this is again deposited at the upper part of the cavity, and thus the rock is recomposed. (*Zool. Proc.*, 1834.) Mr. Garner, in his valuable paper 'On the Anatomy of the Lamellibranchiate Conchifera' (*Zool. Trans.*, vol. ii.), remarks, that there is a cartilage between the two small spinous processes of the hinge in the *Pholas candidus.* In other species which have no rudiment of it, and allied genera which have a particular character of articulation, he considers the motion of the valves as but a secondary cause in the perforation of the substances in which these animals are found. His strictures on the opinions of M. de Bellevue and Mr. Osler with regard to the crypts of *Saxicava* will be found under our notice of that animal in the article LITHOPHAGIDÆ [vol. xiv., p. 51]; and he follows them up by observing that Turton says the valves of the *Teredo* do not correspond with the bore, though Mr. Garner thinks that in this case they do act as mechanical instruments: but, he adds, the *Pholas conoïdes* is often found in hard timber, though its valves do not seem in the least adapted for any boring or filing. See further on this point Mr. Garner's observations on the subject of a supposed solvent fluid in the description of *Lithodomus.* [MYTILIDÆ, vol. xvi., p. 49.] Mr. G. B. Sowerby had previously (*Genera*, No. xxiii.) remarked that the manner in which these and other perforating shells produce the cavities in which they live had long been subject to controversy, and observed that, as he did not wish to add himself to the number of disputants, he would only state that the effect cannot be produced by rotatory motion, since the cavities are fitted to the shape of the shell, and since animals whose shells are perfectly smooth on their outside are equally capable of producing these cavities with others whose external surfaces are rough like a file; nor did he think it could be by the chemical action of any solvent, since the same effect is produced on wood, limestone, and sandstone. He stated that he had been informed that the *Teredo* eats its way into wood, and inquires whether the *Pholas* and others perforate wood, chalk, limestone, and even sandstone in the same manner? or have some of them the power of dissolving stone, while others form their cavities by eating away wood?

Mr. Garner (*loc. cit.*) mentions *Pholas* as one of the genera in which supplementary branchiæ exist, and as one of the forms in which a disposition of those organs different from that observed in *Anomia, Pecten, Arca, Modiola, Unio,* and *Cardium*, &c., where no complete division of the sac of the mantle exists, is found. In *Pholas* the branchiæ are prolonged into the inferior siphon, and as they are not separated from the base of the foot within nor from the mantle without, the water drawn in through the inferior orifice must make its exit by the same or by the anterior opening: but water is likewise drawn in by the superior siphon, and so gets access to the interior interlaminary spaces of the branchiæ (oviducts of some); and by this superior siphon the *ova, fæces*, and secretions are discharged. He also remarks, in another part of his paper, that the oviduct is distinct from the sac in *Modiola, Mytilus, Lithodomus*, &c., whilst in *Tellina, Cardium, Mactra, Pholas, Mya*, and most others, the *ova* are discharged into the excretory organs.

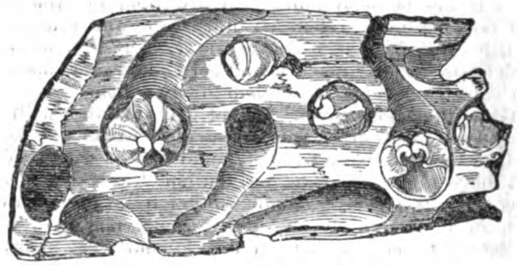
To return to the perforating habits of these animals. The accompanying cuts will convey some notion of their ravages upon the substances which they penetrate:—



Pholas striatus in wood.



A block of stone perforated by Pholas Dactylus.



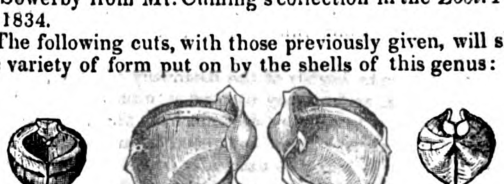
Pholas (Xylophaga) dorsalis in wood.

Pholas has been found at depths varying from the surface to seventeen fathoms, and *Xylophaga* from the surface to forty-five fathoms.

The soft parts of *Pholas Dactylus* and *Pholas crispata* are well shown in the preparations 132, *a, b, c,* and *d*, in the museum of the College of Surgeons (*Preparations of Nat. Hist. in Spirit*).

The species are numerous, and some are very abundant on our own coasts. 'Of these,' says Mr. G. B. Sowerby, '*Pholas crispata, Dactylus, candida,* and *parva*, are the most common; several others are described by Turton, in his *British Bivalves*, of which we are quite convinced the *P. lamellata* is only the young of *P. papyracea:* we are not acquainted with his *P. tuberculata.* Much confusion appears to prevail in regard to several very distinct species among these we believe the *papyracea* of Turton is the *striata* of Montagu; the *clavata* of Lamarck is the *striata* of Linnæus, but not of Mont.'* The number of living species of *Pholas* noted by M. Deshayes in his Tables is fifteen, and of these one, *P. candida*, is recorded as living and fossil. In the last edition of Lamarck, ten species only (including *Xylophaga*) are recorded: this, notwithstanding the errors which have been committed by those who have taken difference of size or age for specific difference, must be far below the mark. For instance, we do not find, in the work last referred to, any of the nine species described by Mr. G. B. Sowerby from Mr. Cuming's collection in the *Zool. Proc.* for 1834.

The following cuts, with those previously given, will show the variety of form put on by the shells of this genus:



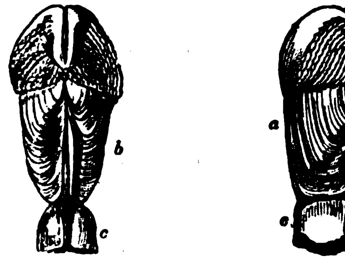
Xylophaga dorsalis.

a, enlarged view of interior; *b*, dorsal view, nat. size; *c*, ventral view, nat. size.

---

* Zoologists sometimes make the word 'Pholas' masculine, sometimes feminine. Linnæus made it masculine, and so it should be considered.

This species, which is found in cylindrical cavities eaten? in wood (see cut at p. 108), bears some resemblance to *Teredo*, but is without the shelly tube, nor has it the posterior hiatus.



Pholas papyraceus.
a, side view; *b*, dorsal view; *c*, cup-shaped membrane.

This is the genus *Pholadidæa* of Leach.

Fossil Pholades.

Mr. G. B. Sowerby (*Genera*) observes that fossil *Pholades* are rare, but that they occur in the calcaire grossier and contemporaneous formations, in several places, and also in our crag: several very interesting specimens, he adds, are found in Italy and in Touraine, as well as in the vicinity of Paris, where these and several other perforating shells have been discovered in a fossil state in the cavities which they have themselves formed. M. Deshayes, in his Tables, gives the number of fossil species (tertiary) as nine; but in the last edition of Lamarck only two appear: one, *P. candida*, recent and fossil; the other, *Pholas Jouanneti* (*Jouannetia*), fossil only. In Professor Phillips's *Illustrations of the Geology of Yorkshire*, we find *Pholas recondita* and *P. constricta* recorded; the first from the coralline oolite, the second from the Speeton clay. In Dr. Fitton's list (*Strata below the Chalk*), we find *Pholas? gigantea* and *prisca* noted; the first from the gault and the lower green-sand, the second from the lower green-sand and Blackdown.

PHONE'MUS, De Montfort's name for a genus of microscopic *Foraminifera*. [Foraminifera, vol. x., p. 348.]

PHONY'GAMA, M. Lesson's name for a genus of birds placed by Mr. Swainson in the subfamily *Corvinæ* of his family *Corvidæ*.

Generic Character.—*Bill* large, strong, considerably compressed; very high at the base, gradually narrowing towards the end; the front advancing on the crown of the head, and considerably dividing the frontal plumes; upper mandible distinctly notched. *Nostrils* very large, placed in a deep depression of the bill; the aperture large, oval. Frontal feathers short, reflected forwards. *Tail* moderate, rounded; the feathers broad, truncate, and ending in setaceous points. (Sw.)

Example, *Phonygama Lessonia* (*Voy.*, pl. 13).

PHORCY'NIA. [Pulmograda.]

PHO'RMIUM, a genus of plants of the natural family of Liliaceæ, tribe Agapantheæ of Endlicher, Asparageæ of Lindley, contains only a single species, which is remarkable for its useful product, so well known under the name of New Zealand flax, and which is found indigenous in New Zealand and Norfolk Island. The genus is characterised by having a coloured tubular perianth, of which the tube is very short, and divides into six segments, of which the three inner are the longest; stamens six, inserted into the base of the tube, ascending exserted; capsule oblong, three-cornered; seeds numerous, compressed; embryo in the centre of the seed, longer than half the albumen, with its radicle next the umbilicus. The root is tuberous, fleshy, and bitter tasted; the leaves are numerous, all radicle, linear-lanceolate, five or six feet long, and from one and a half to two inches broad, two-rowed, equitant at the base, leathery, and very tough. Its flowers are numerous, showy, yellow-coloured, arranged on a tall branch panicle.

The leaves of this plant yield a very beautiful and a very strong fibre, which has been of late imported in considerable quantities under the name of New Zealand flax. It was expected to be much more useful than it has proved to be, in consequence of its having the defect of breaking easily when made into a knot. Being a plant of high southern latitudes, it was supposed that it might easily be grown in different parts of Europe. The French have attempted to cultivate it near Cherbourg, Toulon, and other places, and it has been introduced into Ireland, of which the moist insular climate is probably favourable to its growth. It grew remarkably well for a number of years in the Chelsea Botanic Garden, but was killed by the severe winter of 1837-38. Its cultivation has also been attempted in Australia, but has not yet succeeded to any extent.

PHO'RUS, De Montfort's name for the trochoid form which is loaded with pebbles, shells, &c. (*Trochus agglutinans* of authors, genus *Onustus*, Humph.), generally known to collectors by the name of *Carrier Shells*. [Trochidæ.]

PHOS, De Montfort's name for a genus of turbinated gastropods with a turrited thick shell, which is carinated and varicose; spire pointed, but not produced; aperture rounded or oval; outer lip ridged internally; columella with an oblique plait or plaits; canal short, with the external form of a raised varix. The notch at the extremity of the columella brings this shell into the group of *Entomostomata*, and the raised external surface of the columella very near to *Buccinum;* but the general aspect of most of the species more resembles that of *Murex;* there can hardly however be said to be any true varices on the whorls, the elevations are rather ribs or bars.

Example.—*Phos senticosus.*

PHOSGENE GAS. [Chlorocarbonic Acid Gas.]

PHOSPHORIC ACID. [Phosphorus.]

PHOSPHORIC ACID, MEDICAL PROPERTIES OF. Dry phosphoric acid is sometimes used in the form of pills, but this is not an eligible mode; the common form is that of solution, constituting the dilute acid of the 'Pharmacopœia.' This differs from the other dilute mineral acids in not affecting so strongly the digestive organs, on which account it may be persevered in for a longer time. It is peculiarly suited to disordered states of the mucous surfaces, and also to states of debility, characterised by softening of the bones and a phosphatic condition of the urine. In this latter state it is often more efficacious when combined with iron, in the form of a phosphate of that metal. The same combination is of great utility in most cases of diabetes. In passive hemorrhages, phosphoric acid, properly diluted, quickly arrests the bleeding, as it coagulates the blood. This property is possessed in a stronger degree by the undiluted acid; and hence if injected into a vein, causes death. A poisonous dose of the strong acid may be counteracted by chalk or carbonate of soda.

PHOSPHORUS. This elementary, solid, non-metallic body was discovered in 1669, by Brandt, an alchymist of Hamburg; he kept the mode of preparation for a long time secret, but as he could not conceal the fact of its being obtained from urine, Kunkel tried to procure it from the same source, and he succeeded in the attempt.

It will not be requisite to describe the original mode of preparing this very peculiar substance, and we shall give an outline merely of the method at present employed. It has been shown that animal bone [Bone] contains a large quantity of phosphoric acid combined with lime, forming a subsesqui-phosphate of that earth; and it was first proposed by Scheele to obtain phosphorus from bone; for this purpose the bones are ignited or calcined in contact with the air till they become white; and when this happens it is a proof that the charcoal derived from the decomposition of the animal matter is entirely expelled. In this state they consist of phosphate of lime mixed with little else than a small portion of carbonate of lime. After being reduced to a fine powder, they are digested for a day or two with sufficient water to form a thin paste, and half their weight of sulphuric acid. In this case sulphate of lime is formed, and the greater part of it remains insoluble, and a superphosphate of lime remains in solution; this is to be evaporated in a copper vessel, and the precipitate formed being separated, the clear fluid, which is chiefly phosphoric acid, is to be evaporated nearly to dryness, and mixed with about a fourth of its weight of powdered charcoal; this mixture is to be strongly heated in an earthen retort, the beak of which is immersed in water; by the action of the heat the phosphoric acid yields oxygen to the carbon, and the results are carbonic acid or oxide, which is evolved in the gaseous state, and the vapour of phosphorus, which is condensed by passing into water.

The properties of phosphorus are, that it is solid, translucent, and nearly colourless; but sometimes it has a yellow or reddish tint; it is so soft that it may be indented by the nail, and it is very readily cut. When heated to about 108° it fuses, and at 550° it is converted into vapour; it has a peculiar smell when exposed to the air, but this is probably derived from the action of the oxygen of the air upon it. Neither water nor alcohol dissolves phosphorus, but it is dissolved by æther and by oils. It emits light when exposed to the air in the dark, and hence its name (from φῶς, *light*, and φέρειν, *to carry*). It is extremely inflammable, and has been known to take fire spontaneously in the atmosphere when its temperature was not above 60°. Its specific gravity is about 1·77. Phosphorus is also soluble by the aid of heat in naphtha, sulphuret of carbon, and sulphuret of phosphorus, and on cooling from solution in the last-mentioned it has been obtained in dodecahedral crystals; and by mere fusion and slow cooling of a larger quantity, it has been procured in octohedral crystals.

Oxygen and Phosphorus combine with great readiness, and form several different compounds. We shall first describe the

Oxide of Phosphorus.—This is prepared by melting phosphorus in hot water, and in this state forcing a jet of oxygen gas upon it. The phosphorus burns under water, and the results are phosphoric acid, which remains in solution, and which we shall presently describe, and a red pulverulent body, which remains at the bottom of the vessel, and is the oxide of phosphorus. Its properties are, that it is inodorous and tasteless, and is insoluble in water, alcohol, æther, or oil. It undergoes no change in the air, even when heated to above 600° Fahr.; but at a low red heat it burns. In chlorine gas it inflames. It decomposes nitric acid readily, and combining with its oxygen, it becomes phosphoric acid. It does not possess either acid or alkaline properties.

It is composed of—

One equivalent of oxygen . .	8
Three equivalents of phosphorus .	48
Equivalent .	56

Hypophosphorous Acid was discovered in 1816 by M. Dulong. When phosphuret of barium is acted upon by water, both suffer decomposition, and there are formed phosphuretted hydrogen, phosphoric acid, hypophosphorous acid, and barytes; this earth combines with both these acids, and the phosphate of barytes, being insoluble, is precipitated, while the hypophosphite is soluble, and sulphuric acid being added to the solution, sulphate of barytes is precipitated, and free hypophosphorous acid remains in solution; by evaporating this, a viscid strongly acid substance is obtained, which is hydrated hypophosphorous acid.

The properties of hypophosphorous acid are, that it is liquid, uncrystallizable, has a powerful taste, is heavier than water, and cannot be obtained in a dry state. When subjected to the action of heat, it is quickly decomposed into phosphuretted hydrogen gas, which escapes, and phosphorous and phosphoric acids. Water dissolves this acid in all proportions; it acts very powerfully as a deoxidizing agent, taking oxygen from many compounds containing it: it nevertheless combines with many salifiable bases, forming salts which are termed *hypophosphites;* these salts are remarkably soluble in water; they are usually deliquescent, and crystallize with great difficulty.

Hypophosphorous acid is composed of

One equivalent of oxygen .	8
Two equivalents of phosphorus	32
Equivalent .	40

Phosphorous Acid, like the preceding, is entirely an artificial product; it is obtained in the greatest purity by subliming phosphorus through bichloride of mercury in a glass tube. During the action of the heat, the phosphorus takes half the chlorine from the mercury, and they form a volatile compound which condenses into a limpid liquid. When this chloride of phosphorus is mixed with water, mutual decomposition occurs; the hydrogen of the water and the chlorine of the chloride form hydrochloric acid, while the oxygen and phosphorus unite to form phosphorous acid. By evaporation the hydrochloric acid is expelled, and when it has been continued until the residue, while hot, has the consistence of a syrup, it becomes a solid crystalline mass on cooling, which is hydrated phosphoric acid. This acid dissolves very readily in water; it has a sour taste, reddens vegetable blue colours, and combines with some bases to form salts, which are called *phosphites.*

Phosphorous acid is also formed when phosphorus is burnt in rarefied air. When phosphorus is exposed to air and moisture, it has been long known that a dense sour fluid is formed by the aborption of oxygen: this was supposed by M. Dulong to be a peculiar acid, and he called it phosphatic acid; it was however subsequently shown by Davy to be mixture of phosphorous and phosphoric acids.

Phosphorous acid appears to be composed of

One and a half equivalents of oxygen	12
One equivalent of phosphorus .	16
Equivalent . .	28

Phosphite of Ammonia is procured by adding carbonate of ammonia to the acid to saturation. It crystallizes in deliquescent needles; when heated, it is decomposed, giving out ammonia, and by the continued application of heat the phosphorous acid remaining is converted into phosphoric acid. It is not a salt of any importance.

Phosphoric Acid.—This acid exists largely in nature, not only, as has been already mentioned, in combination with lime, forming bone, but also in some vegetable products, and often in the bowels of the earth, combined with lime, forming a mineral which, when crystallized, is frequently called *apatite.* It also occurs in combination with oxide of iron, copper, lead, manganese, and uranium; but the quantity of these compounds is by no means large, and they are regarded chiefly as objects of curiosity.

Phosphoric Acid may be artificially formed by the direct combination of its elements. When a piece is inflamed, and it is immediately covered by a large bell glass, the phosphorus is converted into white flakes of phosphoric acid, which fall like snow in the vessel. When exposed for a short time to the air, the acid deliquesces, and so great is its affinity for water, that when the solid acid is collected, and a little water is added to it, it is converted into a hydrate with explosive ebullition, owing to the heat which is evolved during combination. Phosphoric acid, when free from water, is exceedingly fixed in the fire, but when the hydrate is heated it is dissipated.

Phosphoric acid is also formed when phosphorus is heated in moderately strong nitric acid; the nitric acid is decomposed, and yields oxygen to form the phosphoric acid. By evaporation in a platina capsule hydrated phosphoric acid is obtained.

Phosphoric acid is composed of

Two and a half equivalents of oxygen	20
One equivalent of phosphorus .	16
Equivalent . .	36

Phosphoric acid is colourless, inodorous, dense, extremely sour to the taste, and acts strongly on vegetable blue colours; it does not however, like sulphuric acid, destroy the skin when applied to it. According to Professor Graham, phosphoric acid is peculiarly disposed to combine with different proportions of water, and these compounds exhibit properties so different, that they might be supposed to be three different acids, instead of different hydrates of the same acid. When the dry acid, obtained as described from the combustion of phosphorus, is thrown into water, a mixture of the three hydrates is obtained in variable proportions, but they may be separately obtained [illegible] a pure state from the common phosphate of soda of the shops; after it has been purified by solution and re-crystallization. Decompose a warm solution of this salt by means of a solution of acetate of lead, and wash the precipitated phosphate of lead, and then pass a current of hydrosulphuric acid through it while suspended in water. When the excess of hydrosulphuric acid has been expelled by heat, a very sour fluid remains, which, according to Professor Graham, is a terhydrate of phosphoric acid; but following the practice of some other chemists, we have reckoned the equivalent of phosphorus at only half the weight which he has done, and consequently this hydrate we regard as a sesquihydrate, composed of

One and a half equivalents of water	13·5
One equivalent of phosphoric acid	36
Equivalent	49·5

This acid is unalterable by boiling its solution or keeping it for any length of time. The class of salts which this hydrate forms are the old or common phosphates, which give a yellow precipitate with nitrate of silver. Common phosphate of soda contains therefore this sesquihydrated phosphoric acid.

Pyrophosphoric Acid. — Professor Clark of Aberdeen first discovered that when common phosphate of soda is heated to redness, it is completely changed in some of its properties, and after being dissolved in water, it affords crystals of a new salt, which he named pyrophosphate of soda. It gives a white precipitate with nitrate of silver, instead of a yellow one. If a solution of this salt be decomposed by one of acetate of lead, and the precipitated phosphate of lead be treated with hydrosulphuric acid as already described, and the excess of it be suffered to escape by exposure to the air, without the application of heat, the remaining solution is hydrophosphoric acid, consisting of

One equivalent of water	9
One equivalent of phosphoric acid	36
Equivalent	45

When saturated with soda, the pyrophosphate is obtained without the further agency of heat. Unlike the sesquihydrate above described, this acid, if exposed for some time to a high temperature, undergoes a change, it being in fact converted into sesquihydrate.

Metaphosphoric Acid.—If biphosphate of soda be heated to redness, a salt is formed which, treated as the last, gives an acid liquor, containing the metaphosphoric acid or dihydrated phosphoric acid.

Glacial phosphoric acid is also in general mostly metaphosphoric acid. This hydrate is characterised by producing a white precipitate in solution of albumen, and in solutions of the salts of earth and metallic oxides; precipitates which are remarkable semifluid bodies, or soft solids without crystallization.

Hydrogen and Phosphorus combine, and in different proportions. According to Magnus, phosphuret of potassium is obtained when these elements are fused together under water; and when this compound is thrown into water, a yellow powder precipitates, which is a solid phosphuret of hydrogen, containing less hydrogen than

Phosphuretted Hydrogen Gas.—This gas was obtained by Gengembre in 1783: it is procured by boiling phosphorus in a solution of potash. The gas which arises is spontaneously inflammable; and during its combustion there are formed water and phosphoric acid: it is colourless, and has a disagreeable odour resembling that of onions. Water dissolves about two per cent. of this gas; but the solution, unlike that of sulphuretted hydrogen gas, has no acid properties. It suffers no change of composition, whether kept in the dark or exposed to light. The specific gravity of this gas, according to Dumas, is 1·761. It is stated that its spontaneously inflammable property is lost by being kept over water: this power, according to Prof. Graham, must depend upon something extraneous; this is shown by the circumstance that the gas which is obtained by heating hydrated phosphorous acid, and which Davy called hydrophosphoric gas, is not spontaneously combustible. It has been further shown by Prof. Graham that the gas is deprived of its power by porous absorbents, such as charcoal, by phosphoric acid, and by a most minute quantity of several combustible bodies, such as potassium, the vapour of æther, and essential oils; and he also discovered that the property was communicated to the gas obtained by either process, by the addition of a very minute quantity of nitric oxide gas, or of nitrous acid, varying from 1-1000th to 1-10,000th of the volume of the gas.

Phosphuretted hydrogen gas decomposes some metallic solutions, such as those of copper and mercury, and metallic phosphurets are precipitated; and when it is pure, it is entirely absorbed by sulphate of copper and chloride of lime.

It is probably composed of—

One and a half equivalents of hydrogen	1·5
One equivalent of phosphorus	16·
Equivalent	17·5

Chlorine and Phosphorus combine in two proportions, forming the protochloride and perchloride.

Protochloride or *Sesquichloride of Phosphorus.*—When a mixture of bichloride of mercury and phosphorus is heated, we have already had occasion to notice that protochloride of phosphorus is produced. When first procured it has generally a reddish colour, owing to the presence of a little uncombined phosphorus. When this has had time to deposit, or when it is purified by slow distillation, it becomes limpid and colourless. It has a suffocating odour, and exhales and fumes when exposed to the air. Its specific gravity is 1·45. It does not alter the colour of dry litmus paper, but if moist, then hydrochloric and phosphorous acids are formed, which redden it strongly. The vapour of this compound is combustible, and acts with great energy upon water, producing the changes which have been described.

It is composed of

One and a half equivalents of chlorine	54
One equivalent of phosphorus	16
Equivalent	70

Perchloride of Phosphorus is obtained by the spontaneous combustion of phosphorus in chlorine gas; a white, flaky, volatile compound is formed, which is the perchloride. It is volatile, rising in vapour at 200°. It is fusible under pressure, and crystallizes in prisms. It reddens dry litmus paper, owing, as has been suspected, to its acquiring oxygen and hydrogen from the decomposition of the paper. Like the protochloride, it acts strongly upon and decomposes water, but the results are phosphoric instead of phosphorous acid, and hydrochloric acid.

It is composed of

Two and a half equivalents of chlorine	90
One equivalent of phosphorus	16
Equivalent	106

Azote and Phosphorus form phosphuret of azote. This compound cannot be obtained by direct action; it is the result of the action of ammonia on the chlorides of phosphorus. The changes which occur are effected with difficulty, but the phosphuret of azote eventually obtained has the following properties: it is a light white powder, and although formed of very volatile constituents, it remains fixed and infusible even at a red heat, when the access of air is prevented; but if that be present, white vapours of phosphoric acid are formed. This compound of azote is remarkable also for its indifference even to the most powerful reagents; it is insoluble in water and in acids, nitric acid even attacking it only after long continued exposure to it. Chlorine and sulphur do not act upon it; it is insoluble in alkaline solutions, but when heated with solid hydrate of potash, ammonia is evolved. It is composed of

One equivalent of azote	14
One equivalent of phosphorus	16
Equivalent	30

Sulphur and Phosphorus may be made to combine by fusion in an exhausted flask or under water, but the operation requires great caution. Mr. Faraday melted seven parts of phosphorus with five parts of sulphur; a reddish-brown liquid was obtained, which was rendered of a light yellow and semitransparent by agitation in solution of ammonia.

This compound remained fluid even when cooled down to 20°, and was perfectly liquid at 32°. After being kept for some weeks in a bottle of water, crystals were deposited which were sulphur, and at the temperature of 40° it became a crystalline mass; the relative proportions of sulphur and phosphorus appeared to be four and eight, and it was therefore probably a bisulphuret, consisting of—

Two equivalents of sulphur	32
One equivalent of phosphorus	16
Equivalent	48

Bromine and Phosphorus combine when brought into contact in a flask filled with carbonic acid gas: heat and light are evolved, and two bromides are formed; one is solid, crystalline, and collects in the upper part of the flask, and the other is fluid, and remains at the bottom.

The liquid compound is probably a protobromide, composed of single equivalents of its elements; this remains liquid at 52° Fahr. When heated it is readily converted into vapour, and on exposure to the air it emits penetrating fumes. It reddens litmus slightly, an effect which is probably derived from the moisture which it contains. When only a small quantity of water is added to this compound, heat is excited by their action, and hydrobromic acid is evolved; in a large quantity of water, the gas is dissolved. The perbromide, while it remains solid, is yellow; but by heat it first melts into a red-coloured liquid, and is afterwards converted into a vapour of the same colour; by fusing it yields rhombic crystals, but by sublimation they are acicular. When exposed to the air, it emits dense penetrating fumes; and on the addition of water to it, it is converted into hydrobromic and phosphoric acids.

Iodine and Phosphorus.—When these substances, perfectly dry, are heated together in an exhausted vessel, they act violently, giving out heat, unaccompanied by light. When the proportions are one of phosphorus and about twelve of iodine, the compound is reddish-brown, very fusible, and is probably a sesqui-iodide of phosphorus. It is decomposed by water, and resolved into hydriodic and phosphorous acids.

When the proportions are one of phosphorus and about forty of iodine, a black and less fusible compound is formed, which is resolved by water into hydriodic and phosphoric acids: it is probably composed of two and a half equivalents of iodine and one of phosphorus.

Selenium and Phosphorus may be made to combine by dropping the selenium into the melted phosphorus. It is an unimportant compound, and is probably a di-seleniuret.

Phosphorus may be made to combine with the greater number of the metals; the most important of these compounds will be found under each particular metal.

PHO'SPHORUS, MEDICAL PROPERTIES OF. This elementary substance exists as an essential constituent both of vegetable and animal bodies; yet when applied in a concentrated and pure state to any organised structure, it acts upon it as a violent and corrosive poison. Into animal bodies it is introduced in a diluted and combined state, by which it is disarmed of its virulence, as an ingredient of many common articles of food. One of the chief sources of it is the starch of the cereal grains, such as wheat-flour, in the ashes of which, when burnt, it amounts to 23 per cent. (Prout's *Bridgewater Treatise*, book iii.); also alliaceous plants, such as onions, in which it exists as a phosphate of iron; polygonous and other plants, in which it occurs as a phosphate of lime. It also exists not only in the bones and other hard parts of animals, but in many of the fluids, especially the excretions. Thus it is found in the milts and roes of fishes, the substance of oysters, the yelk of eggs, in the liver, and also the brain, in which organ of the human being it amounts to from 2 to 2½ per cent.

Phosphorus is of all stimulants the most powerful and diffusible, but, on account of its activity, highly dangerous. Its poisonous action seems to be connected with its strong affinity for oxygen, by which it is converted into phosphorous and phosphoric acids. Hence when brought in contact with the animal tissues, it abstracts oxygen from them, and produces an eschar, resembling a burn: the phosphorus in this way loses weight and is absorbed, so that the exhalation from the lungs and the cutaneous perspiration are impregnated with the vapour, and, under certain circumstances, luminous. A very small quantity of solid phosphorus, even one grain and a half, has proved fatal. Solutions of phosphorus in oils, fixed or volatile, or in æthers, are still more active and dangerous.

Little use is made of phosphorus or its oleaginous solutions in medical practice in Great Britain, though in cases of extreme prostration of the nervous system it is not without its value.

In the event of a poisonous dose being taken, bland mucilaginous fluids should be freely administered, followed by magnesia or chalk.

PHO'TIUS was born in the early part of the ninth century, of a patrician family of Constantinople. He studied in that city, and attained great proficiency in all kinds of learning, which was enhanced by an irreproachable morality. He was noticed by the emperor Michael III., who employed him in various important offices. The emperor sent him on a mission to Assyria (probably Persia is meant), and on his return made him proto-spatharius, or commander of the guards, and proto-secretarius and member of the emperor's privy council. Bardas, the uncle and colleague of Michael, was very partial to Photius; and having, on account of some dispute as to jurisdiction, removed and banished the patriarch Ignatius, he determined to put Photius in his place. Photius, being a layman, took all the various clerical orders one after the other in six consecutive days; and after being ordained priest, he was installed in the patriarchal chair, A.D. 853. But the informality of his appointment was too glaring, especially as Ignatius, although threatened and imprisoned in order to force him to abdicate, refused to do so. A subservient council was assembled at Constantinople, A.D. 858, which deposed Ignatius and confirmed the appointment of Photius. Photius sent two bishops to Rome with letters for Pope Nicholas I., in which he gave a specious account of his election, and invited the pope to send legates to Constantinople, in order to co-operate with him in putting down the remains of the Iconoclastic heresy. The legates came; and a new council being assembled, A.D. 859, which the legates attended, Ignatius was brought before it, and was again deposed on the score of incapacity and other charges, and obliged to sign his own abdication, with the concurrence of the papal legates, who were either deceived, or bribed, or frightened into compliance by the party of Photius.

The see of Rome had for more than a century past been disputing with that of Constantinople on a question of jurisdiction. During the period of the superiority of the Iconoclasts at the court of Constantinople, the patriarchs of that city, supported by the emperors, had appropriated to themselves the spiritual jurisdiction over the extensive provinces of Illyricum, Macedonia, Achaia, and Sicily, which had formerly been subject to the Roman see. A fresh subject of contention afterwards served to embitter the quarrel. The heathen inhabitants of Bulgaria being converted to Christianity by both Latin and Greek missionaries, Photius placed the new churches of Bulgaria under his own jurisdiction, a measure which seemed justified by the proximity of Bulgaria to Constantinople. But the pope alleged that his own missionaries had been first in the field, and that the king or chief of Bulgaria had sent his own son to Rome, which was a sort of acknowledgment of spiritual obedience. In short Nicholas demanded the restitution of the provinces of Illyricum, Macedonia, Achaia, Sicily, and Bulgaria, which Photius stoutly refusing, the pope assembled a council at Rome, A.D. 862, in which he pronounced the election of Photius to be illegal, and excommunicated him with all his abettors. Photius however remained quietly in his see; and in the year 866, having assembled a council at Constantinople, he produced five charges, some relating to doctrine, and others to discipline, against the Roman or Western Church. The charges were proved; and Photius, at the head of his council, excommunicated the pope, and declared him and his abettors to be removed from the communion of orthodox Christians: the charges were:—1, that the Romans fasted on the Sabbath, or seventh day; 2, that they allowed the use of milk and cheese during the first week in Lent; 3, that they forced celibacy on the clergy, the consequence of which, observed Photius, was, that their country swarmed with bastards; 4, that their bishops alone anointed persons with the holy chrism, withholding that power from presbyters; 5, that they had interpolated the Nicene creed on the subject of the Holy Ghost, by adding the word 'filioque,' thus asserting the Holy Ghost to proceed from the Son as well as from the Father, 'a tenet unknown till the fifth or sixth century, and even then only partially admitted by some of the Western churches.' (Photius, *Epistles.*)

In the year 867, after the murder of the emperor Michael, Basilius the Macedonian ascended the throne. It is said by some that Photius refused him the sacrament, and reproached him with the murder of his benefactor. However this may be, Basilius soon after deposed Photius, exiled him to Cyprus, and restored Ignatius to his see; and this act was confirmed by a general council assembled at Constantinople, A.D. 869, which was attended by legates of Pope Adrian II., and in which Photius was condemned. This is called the eighth Œcumenical council, having been acknowledged by both the Eastern and Western churches.

Photius in his exile found means to deprecate the hostility of the emperor, and after some years he was allowed to return to Constantinople. He is said to have composed a genealogy of Basilius, in which he made him descend from Tiridates, king of Armenia. At the end of the year 877, the patriarch Ignatius died; and the canonical impediment to the exaltation of Photius no longer existing, he was replaced on the patriarchal see; and Pope John VIII. was induced to approve his nomination, with the view of restoring peace to the church. In 879 Photius assembled a new council at Constantinople, in which the word 'filioque' was erased from the creed. The separation however between the two churches was not finally consummated till nearly two centuries later, when the patriarch Michael Cerularius, after a long and angry correspondence with Leo IX., was excommunicated, with all his adherents, by the pope's legates, who solemnly deposited the written act of excommunication on the grand-altar of Sancta Sophia, and having shaken off the dust from their feet, departed from Constantinople, A.D. 1054.

In the year 886, Leo, the son and successor of Basilius, exiled Photius, for reasons not clearly ascertained, into Armenia, where the patriarch died some years after; but the epoch of his death is not exactly known. Photius was of an ambitious and turbulent disposition, and this was his chief failing. Much has been written for and against him; the Greek and Protestant writers being mostly in his favour, and the Roman Catholics against him. All however agree in admitting his very extensive learning, which was truly wonderful for his age, as well as his exquisite critical judgment.

The following are his principal works:—1, 'Myriobiblon, sive Bibliotheca librorum quos legit et censuit Photius,' with a Latin translation, fol., 1653. Imm. Bekker published the Greek text, corrected after a Venetian and three Paris MSS., with an index, Berlin, 1824, 2 vols. 4to. The Bibliotheca is a kind of review of the works which he had read, many of which have been since lost. Photius gives a brief epitome of each, adding his own critical judgment of the merits of the writer, and of his statements and opinions. In this manner Photius reviews more than fifty historians, a still greater number of divines, besides orators, philosophers, grammarians, rhetoricians, &c., in all 279 works which he had read and examined. Fabricius (*Biblioth. Græca*, v. 35) gives an accurate list of the works noticed by Photius. 2, a Greek Lexicon, published by Hermann, 4to. Leipzig, 1808: another edition by Porson appeared after his death, under the superintendence of Dobree, London, 1822; it is entitled Φωτίου τοῦ Πατριάρχου λέξεων συναγωγή. E. Cod. Galeano, descripsit R. Porsonus, 2 vols. 8vo. 3, 'Epistles,' fol., London, 1651. 4, 'Nomocanon, being a Collection of the Acts of the Councils, to the Seventh Œcumenical, with the corresponding decrees of the Emperors concerning Ecclesiastical Matters,' Basle, 1652. 5, A treatise, 'Adversus Latinos de Processione Spiritus Sancti,' and other theological and controversial works, several of which are still unpublished: among others, one against the Paulicians, of which Montfaucon gives some fragments in his 'Bibliotheca Cosliniana.' 6, 'Amphilochia, being Answers to Questions relative to various Passages in the Scriptures, with an Exposition of the Epistles of St. Paul.'

PHOTOGENIC DRAWINGS, facsimile representations of objects produced according to the recent discovery of M. Daguerre, mechanically by the chemical action of light on a prepared metallic tablet, upon which the images of the objects are thrown by a camera-obscura. Such apparatus is named after its inventor the Daguerrotype, and the process itself either photogeny, photography, or heliography (sun-drawing). The invention was first formally communicated to the public by M. Arago, who read an account of the Daguerrotype before the Academy of Sciences, January 7th, 1839. From that moment Daguerre (who was afterwards rewarded by a pension by the government) and his invention engrossed general attention. The discovery was spoken of as little short of miraculous; and as having realised what had long been considered a hopeless desideratum, namely, the giving permanency to the beautiful pictures produced by the camera-obscura, with the exception indeed of colour and motion, on both of which, the latter quite as much as the first, the peculiar charm of the camera-obscura depends; whereas the slightest degree of motion, even that of clouds and trees, is positively injurious to the action of the Daguerrotype, producing indistinctness of form, and blurring those parts of the picture which are affected by the motion. Hence not only powerful sunshine, but perfect stillness in the atmosphere is required for its successful operation, and its practical usefulness becomes limited to the delineation of buildings, sculptures, and other inanimate objects, more especially such as are independent of sunshine, and which may at any time be copied by means of a sufficiently strong artificial light thrown upon them.

Still, though, even after the great improvements since made in it, the powers of the Daguerrotype are so far circumscribed, the invention is highly valuable, because it not only ensures perfect fidelity of likeness where it is most essential, and where it is hardly attainable by the most practised and patient hand and eye, but also gives us the minutest details—those which are imperceptible to the naked eye, and of course cannot possibly be represented upon paper, yet become visible in a photogenic drawing when it is examined with a magnifying-glass. If therefore the Daguerrotype should be found susceptible of no further improvements, it will still be an invention of the greatest utility to art, since by means of it facsimiles of the most beautiful and valuable works, of the finest buildings and statues, of the most elaborate carvings and designs, furniture, &c., may be obtained with great expedition. Nevertheless, now that the first novelty has worn off, the interest taken by the public in the discovery has greatly diminished. This is easily accounted for, since besides that the class of objects for which it peculiarly recommends itself are not appreciated by the many, there certainly are defects and inconveniences attending photogenic drawings: the principal one is, that they must be upon metallic tablets with a highly polished surface; consequently their appearance is not that of a print or drawing, but of an engraved steel plate, devoid of any general effect as to light and shade, and producing a glare offensive to the eye, in order to avoid which it is necessary to hold the tablet in a particular direction. The metallic tablets render them expensive, and their material and fitting-up (as each plate is fixed upon a pannel, and protected by a glass over it) makes it difficult to keep any number of them, except in cabinets with shallow drawers for the purpose. Neither can they be hung up in frames, since in addition to their appearing only like so many polished plates of metal, it would be necessary to take them down whenever it was required to look at them.

More recently M. Bayard has found out a method of taking similar delineations by means of the camera-obscura upon paper, which, besides having the advantage of being much cheaper, and capable of being kept like prints, are said to be far more pleasing to the eye, and in fact to have nearly the effect of sepia drawings. But on the other hand they fall infinitely short of metallic photogenic drawings; for not only is the outline of objects less distinct, but no more can be shown than what appears to the naked eye, no further details being rendered visible by the use of a convex lens. This invention is however at present quite in its infancy, and may possibly receive great improvements, although it is not at all likely that it will ever be able to accomplish what is the most wonderful and valuable characteristic of the Daguerrotype drawings, namely the delineation of objects as they really exist, with all those minutiæ which are invisible to the naked eye.

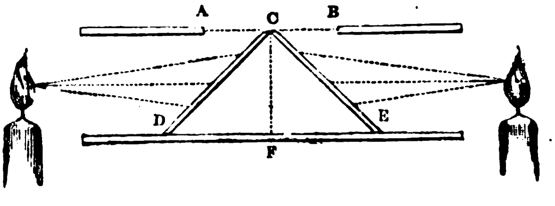
Photogenic drawings are produced upon plates of copper coated over with silver, which are found to answer better than such as are entirely of the last-mentioned metal. After being washed with a solution of nitric acid, the plate is put into a well-closed box, where it is exposed to the action of iodine, a small quantity of the latter being placed at the bottom of the box with a thin gauze between it and the plate. A layer of ioduret of silver is thus formed on the surface of the plate, and manifests itself by the yellow hue produced on the silver, which shows that the process of giving the plate the sensitive coating on which the action of light delineates objects is completed. Thus prepared, the plate is next placed within a camera-obscura of particular construction, and the delineation of the object is then effected in a very short space of time, but has to be afterwards brought out and rendered distinct by another operation, namely submitting the plate to the action of vapour of mercury. Even then the process is not completed, for the plate has to be plunged into a solution of hyposulphite of soda, and afterwards washed in distilled water, which being done, the impression is fixed, and the plate may be exposed to light with perfect safety. For further details and instructions relative to these different operations, the reader may consult the 'Handbook of Heliography,' London, 1840. But as yet the art is only in its infancy, and yery great improvements in it may be looked forward to.

PHOTO'METER (literally 'light-measurer,' from φῶς and μέτρον), the name given to instruments constructed for the purpose of measuring the relative illuminating powers of different sources of light. When light or heat falls upon any substance, it is disposed of either by reflection, absorption, or transmission, or else by two of them, or all three of them combined. If two substances could be found which would reflect, absorb, and transmit calorific rays with the same intensity, and likewise reflect luminous rays equally, but differ in their powers of absorbing and transmitting light, we should then possess the means of at least ascertaining whether the absorption of light alone will produce effects analogous to what is observed to follow the absorption of caloric. For this purpose it would be only necessary to prepare a differential thermometer whose bulbs were of the substances possessing the properties alluded to. The calorific rays accompanying the incident light would, by acting equally upon the two bulbs, produce no change in the indications of the instrument, and the only alteration, if any, which could ensue, would arise from the unequal absorption of light by the two bulbs. This alteration however, when observed, though it might be considered a correct measure of the quantity absorbed, could not be taken for a measure of the quantity or brightness of the incident light, unless it could be further shown that the quantity absorbed by the same substance is proportional to the quantity of incident light, whatever may be its nature, that is, whether it be solar light, gas light, &c.

The photometer invented by Leslie differs from the instrument we have supposed merely in its being in some respects less deserving of the name. It consists of a differential thermometer having one of its bulbs of plain transparent glass, the other of the same material coated either with Indian-ink or black enamel, and is described by its author in the article 'Meteorology' in the *Encyclopædia Britannica*, wherein he observes,—'The rays which fall on the clear ball pass through it without suffering obstruction; but those which strike the dark ball are stopped and absorbed at its surface, where, assuming a latent form, they act as heat. This heat will continue to accumulate till its further increase comes to be counterbalanced by an opposite dispersion, caused by the rise of temperature which the ball has come to acquire. At the point of equilibrium therefore the constant accessions of heat derived from the action of the incident light are exactly equalled by the corresponding portions of it again abstracted in the subsequent process of cooling. But in still air the rate of cooling is, within moderate limits, proportional to the excess of the temperature of the heated surface above that of the surrounding medium. Hence the space through which the coloured liquid sinks in the stem will measure the momentary impressions of light, or its actual intensity.' Allowing that the light incident upon the clear ball is wholly transmitted, and that that which strikes the dark ball is wholly absorbed, assumes a latent form, and then acts as heat, it by no means follows that the effect produced upon the instrument was wholly or even chiefly attributable to the absorption of light, since we learn from Leslie's own experiments (*Heat*, p. 87) that the calorific rays which accompany the incident light would be more abundantly absorbed by the dark than by the light ball. This has since been so satisfactorily established by the observations of Thomson and others, that, as a measurer of light, the instrument may be regarded as useless.

The defects of Leslie's photometer were to a considerable extent obviated by Mr. Ritchie, the late professor of natural philosophy in the London University College, and then rector of the academy of Tain, who, in 1825, communicated to the Royal Society the description of a new photometer. In order to intercept the calorific rays accompanying the light experimented upon, he transmitted the latter through a thick circular disk of glass into a metallic air-light cylinder, the diameter of which was considerable compared with its depth. The axis of the cylinder was placed horizontally, and the aperture covered by the glass was the only one through which the light was admitted. Across the interior of the cylinder was stretched a circular sheet of dark paper, which absorbed the transmitted light, and, as was supposed, thereby converted it into heat, which became sensible by its expanding the air within the cylinder. A second cylinder of the same form and construction was placed by the side of the first so that the line of axes might coincide, but with the aperture for the admission of light turned in the contrary direction, and in that position they were connected by a bent thermometer tube containing a coloured fluid, which served to prevent the air of one cylinder mixing with that of the other. So long as the air in the two cylinders possessed the same degree of elasticity, the level of the fluid in the two branches of the tube was of course the same; and a variation of level indicated a variation in the elasticity of the two bulks of air, arising from the more energetic action of the medium admitted through one aperture than through the other. To compare the relative intensities of two lights, the instrument was placed anywhere between them, and approached towards one or the other, until it was found that the position of the fluid in the tube was the same as when the instrument was not under the influence of the lights. Supposing the whole of the calorific rays and none of the luminous rays to have been intercepted by the glass, this position determined the point at which the intensity of the two lights was the same; and hence, since the intensity of light varies inversely as the square of the distance from its source [LIGHT, p. 472], it followed that at equal distances from their respective sources their intensities were directly proportional to the squares of their observed distances from the instrument.

More recently the same gentleman constructed a very simple instrument which affords an almost unerring measure of the relative brightness of two lights, provided they are of the same colour. The principle originated with Bouguer, who published it in his 'Traité d'Optique,' in 1760. The annexed figure represents a vertical section of the instrument. It consists of a rectangular box open at both ends and blackened upon its inner surface. On the top is a long narrow rectangular slip AB, covered with tissue or oiled paper. Within are two sheets of plane looking-glass, CD and CE, cut from the same slip to ensure uniformity of reflexion. Each sheet has the same width as the box, and its length equal to the hypothenuse of a right angled isosceles triangle, whose side is the height of the box. Their reflecting surfaces are turned towards the open ends of the box, and their upper extremities rest against each other along a line, which in the figure is projected into the point C, and which divides the aperture AB into two equal parts, separated by a narrow strip of black card to prevent the mingling of the lights reflected from the two planes. In using the instrument, it is placed between the lights whose intensities are to be compared, so that they may be reflected from CD and CE upon the tissue AB. It is then approached nearer to one or the other until, to an eye situated above AB, the two portions AC and BC appear equally illuminated, which, on account of the immediate proximity of AC and BC, may be determined with tolerable correctness; the colour of the two lights being supposed the same. The distances of the lights from the vertical CF being measured and squared, give the direct ratio of the intensities as before.



It remains to notice a mode of comparing the illuminating powers of two lights suggested by Count Rumford, which is remarkable for the facility with which it may be applied, and the simplicity of the requisite apparatus, nothing more being needed than a smooth surface of small extent and of a light uniform colour, and a blackened stick for throwing a shadow. The surface is illuminated by the two lights experimented upon, which are to be so placed, that when the stick is interposed between them and the surface, the two shadows may be nearly in contact, which will enable the eye to decide whether they are of equal depth, and will at the same time ensure the intercepting of rays equally inclined to the surface. So long as the shadows are of unequal depth, one of the lights must be brought nearer to or retired farther from the surface till an equality of depth is obtained, and then the squares of the perpendicular distances of the lights from the surface give the ratio of their intensities. If an equality between the inclinations of the intercepted rays to the surface cannot be obtained, then, when the two shadows are of the same depth, the intensities of the lights will be directly proportional to the squares of their perpendicular distances from the surface, and inversely proportional to the sines of the inclinations of the intercepted rays to the surface.

The last two methods are theoretically perfect, when applied to lights of the same colour; those which precede, though independent of the colour of the light, rest upon hypotheses which, if not untrue, are unestablished.

(For further information the reader may consult Lambert's *Photometria*; the article 'Light' in the *Encyclopædia Metropolitana*, by Sir John Herschel; *The Edinburgh Philos. Trans.*, x., part 2; *The Transactions of the Royal Society*, 1825; and Brewster's *Journal*, 1825, ii., pp. 321 and 339; iii., p. 105: and 1830, iii., new series, p. 284.)

PHRAA'TES. [Parthia.]

PHRAGMI'TES, or the Reed, is a plant formerly regarded as a species of Arundo, but now separated from that genus on account of its lower floret being male while the others are hermaphrodite, and its rachis being fringed with long silky hairs. It is a tall plant with annual stems and a perennial root, and is found exclusively in places overflowed even during summer. In such situations it occurs all through Europe, and is common in Siberia, Japan, North America, and even New Holland, forming thick coverts, and yielding an abundance of stout durable grass of great value for the purpose of thatching the roofs of buildings. This is undoubtedly the phragmites (φραγμίτης) of the Greeks. A second species is said to grow in Egypt, and a third in the Isle of France; the two latter species are however little known.

PHRAGMO'CERAS, Broderip's name for a genus of camerated shells found hitherto only in a fossil state.

Generic Character.—Animal unknown.

Shell incurved and compressed, more or less conical; septa entire at their edges, crossed externally by the lines of growth; siphuncle near the inner margin; aperture contracted at the middle, its outer extremity produced into a subcylindrical beak.

This genus is distinguished from *Orthoceras* by being curved, and having a nearly marginal siphuncle; and also from all the species of that genus except *O. piriforme*, by the form of the aperture, which further distinguishes it from *Cyrtoceras* of Goldfuss, the aperture of which is round.

Three species, *P. arcuatum*, *P. ventricosum* (*Orthoceratites ventricosus?* Steininger), and *P. compressum*, from the lower Ludlow rock, are figured in Murchison's great work on the Silurian System; where another species, *P. nautileum*, is also figured with a ? as to the genus.

PHRANZA. [Byzantine Historians.]

PHRAORTES. [Media.]

PHRASE, in Music, a succession of sounds either in melody or harmony, expressing an unbroken sense more or less complete, and terminating in a pause (*repos*), *i.e.* a comparatively long note or a rest: thus forming a cadence more or less perfect.

Such is Rousseau's definition of a term concerning which no two writers are agreed, and, in our opinion, a better cannot be given without entering much more at large into the subject than the nature of this work will allow. Those who desire further information on a matter chiefly interesting to composers, may find much in 'An Essay on Music,' by the Rev. W. Jones, F.R.S.; in Riepel's *Anfangsgründe*, &c. (Elements of Musical Composition); in Kollmann *On Harmony*—who uses the word *Period* instead of Phrase; and, above all, in Reicha's *Traité de Mélodie*, 2nd edit., Paris, 1832.

PHRENOLOGY (from φρήν, mind, and λόγος, discourse) is, in the words of Dr. Spurzheim, the doctrine of the special faculties of the mind, and of the relations between their manifestations and the body, particularly the brain. Without entering upon the question of the nature of the mind, or of the number or nature of its original faculties, it may be admitted as the result of all observation, and a fact on which nearly all physiologists are agreed, that the brain is the part of the body by means of which all the powers or faculties of the mind are manifested. The fundamental principles of phrenology, and those in which it chiefly differs from other psychological systems are, that the manifestation of each of the several faculties of the mind depends on a particular part of the brain, and that, *cæteris paribus*, the degree or strength in which each faculty is manifested in each individual, depends on the size of its appropriated portion of the brain, or (as it is termed) its organ.

The first principle, that of the plurality of organs in the brain, is supported, 1, by the analogy of the other compound organs or systems in the body, in which each part has its special function; as, for example, in the digestive system, in which the stomach, liver, and other organs perform each their separate share in the common result of digestion of the food; 2, by the different degrees in which, in different individuals, the several mental functions are manifested. Even in the earliest period of childhood, and before education can be imagined to have exercised any influence on the mind, children exhibit the most varied dispositions—each presents some predominant propensity, or evinces a singular aptness in some study or pursuit; and it is a matter of daily observation that every one has his peculiar talent or propensity. But it is difficult to imagine how this could be the case, if the manifestation of each faculty depended on the whole of the brain; different conditions of the whole mass might affect the mind generally, depressing or exalting all its functions in an equal degree, but could not permit one faculty to be strongly and another weakly manifested. 3, The plurality of organs in the brain is supported by the phenomena of some forms of mental derangement. It is not usual for all the mental faculties in an insane person to be equally disordered; it often happens that the strength of some is increased, while that of others is diminished; and in many cases one function only of the mind is deranged, while all the rest are performed in a natural manner. 4, The same opinion is supported by the fact that the several mental faculties are developed to their greatest strength at different periods of life, some being exercised with great energy in childhood, others only in adult age; and that as their energy decreases in old age, there is not a gradual and equal diminution of power in all of them at once, but, on the contrary, a diminution in one or more, while others retain their full strength, or even increase in power. 5, The plurality of cerebral organs appears to be indicated by the phenomena of dreams, in which only a part of the mental faculties are at rest or asleep, while the others are awake, and, it is presumed, are exercised through the medium of the parts of the brain appropriated to them. 6, It is stated that the examination of the brains of individuals, each remarkable for some peculiar propensity or talent, has demonstrated a constant correspondence in the development of a certain portion of the brain; and that thus the results of the observations upon which phrenology was first founded by Dr. Gall, exactly coincide with and confirm the arguments by which its truths may, *à priori*, be made to seem probable. Lastly, pain has sometimes been felt in an organ when the faculty with which it is presumed to be connected has been greatly excited; and when a faculty has been morbidly manifested during life, disease has sometimes been found to have affected the corresponding part of the brain.

The preceding arguments for the existence, in the general mass of the brain, of several organs or instruments for the manifestation of the different powers of the mind, form also the basis of the rules by which those powers which may be called primitive, or original, are determined. Every power of the mind is regarded by phrenologists as a primitive faculty, and is considered to be manifested through the medium of a separate organ, which, 1, exists in one kind of animal and not in another; 2, which varies in the sexes of the same species; 3, which is not proportionate to the other faculties of the same individual; 4, which does not manifest itself simultaneously with the other faculties, that is, which appears or disappears earlier or later than they; 5, which may act or repose singly; 6, which individually is propagated in a distinct manner from parents to children; and 7, which singly may preserve its proper state of health or be affected by disease.

In accordance with these rules Gall enumerated nearly thirty primitive mental faculties, which are admitted, with more or less of modification, by all the phrenologists of the present day; and their number has been augmented by Spurzheim to thirty-five. These faculties Spurzheim divided into moral, or affective, and intellectual. The affective faculties or feelings he again divided into *propensities*, including all those which produce only desires or inclinations, and *sentiments*, including such as not only produce a desire to act, but are combined with some other emotion or affection which is not mere propensity. The intellectual faculties also he divided into the *perceptive* and the *reflective*. The subjoined figures and the references to them will at once indicate this division of the mental faculties, and the situations on the exterior of the head which are supposed to correspond with the portions of the brain belonging to each, according to the system of Dr. Spurzheim. We have also added the figures by which the several organs were marked by Mr. Combe, in the two first editions of his 'System of Phrenology;' in the later editions he has followed the enumeration of Dr. Spurzheim.

28.	32.	Melody.
29.	33.	Language.
		II. *Reflective.*
30.	34.	Comparison.
31.	35.	Causality.

1. Amativeness is the mental faculty which produces the propensity to physical love, or, as it was termed by Dr. Gall, the instinct of propagation.[*] Its organ is the cerebellum, and its energy is indicated by the extent of the space on each side of the head between the mastoid process, immediately behind the ear and the spine of the occipital bone.

2. Philoprogenitiveness is the faculty which produces the feeling of love towards offspring. The evidence by which this is admitted as a fundamental faculty of the mind may afford an example of the application of the seven rules already given for determining them. There are many animals which take no care of their progeny, as reptiles, and fish, and, among birds, the cuckoo. In many species of animals the females alone take care of their offspring, as among cats, cattle, sheep, &c., and in general, even when both parents protect their young, the attachment of the mother is the stronger. The love of offspring bears no proportion to the other mental faculties, but is shared alike by men and brutes, and among the former is often felt as intensely by the most degraded as by the most exalted of the species. The love of offspring is sometimes, on the contrary, almost completely suppressed. Cases of insanity have not unfrequently occurred in which parental love was lost or greatly diminished; while others are recorded in which the love of offspring has been almost the only feeling which remained unimpaired. The seat of this organ is directly above the middle of that of amativeness; and the energy of the faculty is indicated by the general protuberance of the occipital bone. Though placed in the middle of the head, this organ is of course, like all the others, double, and extends to an equal distance on each side of the median line.

3. *Inhabitiveness.*—The existence of this, the propensity to inhabit particular regions or countries, which produces the love of home, and which determines in each species the dwelling and mode of life which is best adapted to it, is regarded as doubtful. Dr. Gall placed in this situation the organ of pride in man, and that of the instinct in animals which prompts them to seek and inhabit the heights of mountains or to fly high in the air, believing that faculties which are merely physical in brutes may become moral in man, and that there is an analogy between the feelings which prompt to the pursuit of moral and those which excite the desire of physical elevation. Mr. Combe and many of the Edinburgh school of phrenology name this the organ of concentrativeness, believing that it corresponds to the faculty of maintaining two or more powers in simultaneous and combined activity, so that they may be directed towards one object, a faculty disposing to sedentary pursuits, and a close and steady attention, especially by meditation, to a given object. At present it is agreed that the evidence is insufficient for the complete establishment of either of these opinions.

4. Adhesiveness is the propensity to attachment or friendship, by which individuals of the same or different kinds are induced to associate together, and which causes men to be attached to the various objects amongst which they are placed. Its objects are disinterested friendship, marriage, society, and attachment in general. The organ of this faculty is believed to be situated at No. 4, immediately above and to the outer side of that of philoprogenitiveness.

5. Combativeness is the natural disposition which men and animals feel in various degrees to quarrel or fight. In order to discover its organ, Dr. Gall is said to have been in the habit of calling together boys from the streets to endeavour to make them fight. There were of course some who were fond of it, and others who were peaceable and timid: in the former the part of the head marked 5 was prominent; in the latter it was flattened or depressed. The same difference is said to exist in the formation of this part, in correspondence with the strength of this disposition in the

---

[*] It may be necessary to mention that the chief modifications introduced into the system of Gall by Spurzheim (whose arrangement is here adopted as being received by the great majority of phrenologists in this country) are expressed in the differences of their terms. Gall designated the organs according to the actions to which he believed their predominance led; Spurzheim according to the nature of the faculties. Thus that which Gall called the organ of murder, Spurzheim named the organ of destructiveness, observing that, though many in whom this organ was greatly developed had committed murder, yet many others, though having a propensity to destruction, had never destroyed human life nor felt any inclination to it. So also Gall's organ of theft is named by Spurzheim the organ of Acquisitiveness, a faculty which gives the propensity to acquire without reference to the means, which, in a man with largely developed conscientiousness, would be honest, but in one without the latter faculty would be theft or fraud of some kind. It will be seen that in Spurzheim's nomenclature the sphere of activity of each faculty, as he terms it, is much more extended than in Gall's. [See further, GALL; SPURZHEIM.]

several species of animals, and remarkably in the different varieties of dogs.

6. Destructiveness, or the propensity to destroy, is the feeling which is gratified by any kind or mode of destruction. Spurzheim ascribed to it the tendency to all kinds of destruction, whatever were their objects, or the mode in which they were effected. Thus defined, the propensity to murder is but one of the directions which the disposition for destruction may take, and one from which in a conscientious and benevolent man it would always be diverted. In such a man this propensity will be exercised for an innocent or even a useful end, as the procuring of food by the slaughter of animals, &c.; in another, in whom its influence is less counterbalanced, there will exist an indifference to the suffering and calamities of others, or even a positive pleasure in beholding or contemplating them; in a third, in whom it is unrestrained, it may break out in acts of violence and love of blood-shedding in every form. In the diseased condition of its organ this propensity is regarded as the source of the irresistible desire for the destruction of life, of which so many lamentable examples are known, and which is commonly called homicidal monomania. The seat of the organ of destructiveness is on each side of the head immediately above the ear, at No. 6; and its various degrees of development may be seen in a comparison of the width at this part of the heads of carnivorous and herbivorous animals.

7. Secretiveness is the propensity to act in a clandestine manner; to conceal emotion, and to be secret in thoughts, words, things, and projects. Its most frequent bad results are cunning and hypocrisy; and the most usual direction which it takes for good ends is prudence. The organ of this propensity is immediately above that of destructiveness, at No. 7. (In the casts made in accordance with the enumeration of the faculties employed by Mr. Combe, in the early editions of his 'System of Phrenology, this organ is marked 9.)

8. Acquisitiveness is the propensity to acquire. Its organ being found very large in notorious thieves, Dr. Gall conceived that there was a natural disposition to theft. Dr. Spurzheim, on the other hand, makes no limitation as to the purpose or mode of acquisition, which he believes to be determined in each case by the degrees in which the several other faculties are developed. Variously modified, the propensity leads in some to the prudent accumulation of property by honest means; in others, to avaricious and purposeless money-making by any method; in others, to theft or fraud. The seat of its organ is at the back part of the temples.

9. Constructiveness is the faculty which leads to construction of all kinds: guided by it birds build their nests, rabbits burrow, beavers make their huts; and men are directed by it to manufactures, the practice of the several branches of the fine arts, building, and various manual operations. Its organ is situated at the lower part of the temple, at 9.

10. Self-esteem is the sentiment which gives an individual a high opinion of himself, which in excess produces pride and arrogance, and when moderate and modified by other superior faculties imparts dignity to the mind, and renders it hostile to everything that is mean or degrading. In a state of derangement the morbid excitement of this faculty leads the insane to imagine themselves exalted to thrones or to divinity. The seat of its organ is at the middle of the upper and back part of the head (10), directly above inhabitiveness (3), with which Dr. Gall (as already mentioned) confounded it.

11. Love of Approbation, according to Dr. Spurzheim, is the sentiment which makes us regard the opinion entertained of us, and induces the question—What will the world or the people say? It is fond of approbation in general, without attending to the manner of acquiring it; and may therefore be directed to objects of the highest importance, as well as to such as are of no moment, or are even hurtful. Ambition is the distinguishing epithet of its agency, if the subject aspired to be of great importance; vanity, if claim be laid to distinction on the score of trifles. The organ is seated on each side of self-esteem; when much developed it generally elongates the upper and back part of the head, but is sometimes spread out laterally so as to widen rather than lengthen it.

12. Cautiousness is the disposition of the mind which leads a man or an animal to take precautions in whatever he has to do; 'it doubts, says *but*, and continually exclaims *take care*' (Spurzheim). When too active it causes irresolution, anxiety, and melancholy. Its organ is situated on the upper lateral and posterior part of the head, between destructiveness and self-esteem.

13. Benevolence is the disposition of the mind from which result compassion, kindness, philanthropy, mildness, charity, and various other amiable social virtues. Its existence as a fundamental power of the mind is considered to be proved by the rules above mentioned, and by which, it may be again observed, the existence of all the preceding and following faculties is determined; the seat of its organ is the upper and middle part of the forehead, just where the hair begins to grow.

14. Veneration. The organ of this faculty was called by Dr. Gall the organ of religion, and he believed that the disposition to the worship of God was directly proportionate to its development. Dr. Spurzheim has here again extended the scope of the faculty, by making it the cause of veneration or respect in general, whether directed to divine or human beings, or to inanimate objects. When the organ of this sentiment is much developed, the head is remarkably elevated, and it was by observing (as Lavater had before done) this peculiarity in the shape of the heads of very pious persons, that the position of the organ on the front part of the top of the middle of the head was determined.

15. Firmness is the faculty which gives constancy and perseverance to the other powers, and contributes to maintain their activity. In its various combinations with other faculties the results to which it leads differ considerably; with much self-esteem and love of approbation it produces an obstinate persistence in the pursuit of honour and rank; with benevolence it excites the most active and persevering philanthropy; with destructiveness and acquisitiveness it may excite to daring acts of murder and rapine. When, on the other hand, this faculty is little developed, it leaves men inconstant, and makes them the mere creatures of circumstances. Its organ is situated at the very top of the head, at 15.

16. Conscientiousness is the fundamental and innate sentiment which disposes mankind to look and to wish for justice. The existence of this feeling in a high degree is one of the chief constituents of a noble mind, and the strongest foundation of morality; its deficiency leaves men with little restraint to prevent them from following the impulses of all their worse propensities, and from striving to attain their ends by the most unworthy means. The situation of the organ of conscientiousness is on the upper part of the head, on each side of that of firmness.

17. Hope is the sentiment which induces men to believe in the possibility of whatever their other faculties desire; it is not mere desire, for that may continue without any hope of being ever gratified. The different degrees in which it is developed will lead one person to be continually building, as it is said, castles in the air, and another to despair of success even in favourable circumstances. It is this sentiment also which inspires the hope of a future state and of immortality. Its organ is situated on each side of that of veneration.

18. Marvellousness is the sentiment which is principally manifested by a belief in miraculous and supernatural circumstances, and which leads men to be amused with everything that can excite their surprise and wonder. Its organ is situated immediately in front of that of hope.

19. Ideality. Dr. Gall regarded the organ of this faculty as the organ of poetry, finding it much developed in all the great poets of antient and modern times. But it is also large in some, who though they may be fond of poetical conceptions, are not poets themselves. Dr. Spurzheim therefore believes that the essential nature of this sentiment is to impress a peculiar character called poetical or ideal, and to vivify the other faculties; to give a sense and love of beauty; to produce sublimity of conception, and excite warmth of imagination and expression. The organ of this sentiment is placed by the side of marvellousness, and the two frequently act together.

20. Mirthfulness or Wit. Spurzheim regards this faculty as affective, not as intellectual, in which view it is considered by Gall, and by the principal phrenologists of the Edinburgh school. He describes it as a sentiment which disposes men to view everything in a gay or joyful manner, and which, according to its various applications in different circumstances, and its modifications by being variously combined with other faculties, produces wit, good humour, caricature, mockery, irony, sarcasms, epigrams, and satires. Its

organ is situated in the upper and lateral part of the forehead, and in the earlier Edinburgh casts is marked 32.

21. Imitation. Those who have this faculty highly developed are fond of acting and of imitating the gestures, voices, manners, and in general all the manifestations of man and animals. It is generally more active in children than in adults: the former always learn a great deal by imitation; of the latter some only employ it much, and these are usually marked by the gestures with which they speak, imitating the habits and manners of whatever forms the subject of their conversation. Its organ is situated at the front of the head, and on each side of benevolence.

22. Individuality is in Spurzheim's arrangement the first of those intellectual faculties which perceive the existence of external objects and their physical qualities. It is the faculty which recognises the existence of individual beings. It is this also which in excess induces men to personify everything of which they speak, whether mere qualities or abstract ideas, or even phenomena, such as motion, life, the passions, &c. Its organ is situated behind the root of the nose, and its greater development enlarges the forehead between the eyebrows.

23. Configuration is the power which takes cognizance of forms and figures generally. One of its peculiar applications, and that by which its organ was first discovered by Dr. Gall, is observed in the power which some individuals possess of remembering the forms and features of different persons; another is shown in the love of portraits, or in the ability to take the likenesses of persons and things. Its organ is situated in the internal angle of the orbit, and when large it pushes the eyeball outwards and downwards, giving the person in whom it is thus developed a somewhat squinting appearance, and making his eyes appear unusually wide apart.

24. Size. This is the faculty which measures the size of bodies, as distinguished from their form, which is appreciated by the preceding power. Its organ is placed at the inner corner of the arch of the eyebrow.

25. Weight. It is believed that the mind estimates the weight and resistance as well as many of the other qualities of bodies, not by the sense of feeling, but by a peculiar internal operation, which must require a special organ. Dr. Spurzheim conjectures that its situation is behind the orbit, in the neighbourhood of configuration and size.

26. Colouring. There appears to be a peculiar faculty for the full appreciation of the relations of colour. For though few are incapable of perceiving the differences of colour in the objects around them, yet all have not the same power in this respect, nor have all the same facility in recollecting or judging of their relations. Many artists who draw well cannot colour; others are good colourists, but cannot imitate or design forms. The organ of this power, which must from these and other similar circumstances be regarded as an original faculty of the mind, is placed in the middle of the arch of the eye-brow.

27. Locality. This is the faculty by which we appreciate and remember the places occupied by objects around us; the mental power which makes the traveller, geographer, and landscape-painter; which recollects localities, and gives notions of perspective. It is remarkably shown in the power which many animals exhibit in tracing their way through great distances in migration, or in returning to their homes; and it gives men the propensity to travel, which many have so remarkably exhibited. Its organ is placed above and on each side of the root of the nose.

28. Calculation might be called the faculty of arithmetic; whatever concerns number or calculation belongs to it, and hence Mr. Combe and many others speak of its organ as that of number. In those in whom the power of calculating is much developed, the external angle of the eye-brow is either much pressed downwards or elevated; the organ of this faculty being situated beneath that part of the brow.

29. Order. It is believed that there is a faculty which gives a disposition to arrange and put things in order; as for example, in a library to place books according to their size and form, in a collection of natural history to make each object occupy its right situation according to its configuration or colour or size. Cleanliness also seems to depend on it, and it produces the pleasure of seeing things complete. Its organ is situated between those of colouring and calculation.

30. Eventuality. Individuals who have this organ large; are attentive to all that happens around them, to phenomena, to events, to facts; they are fond of history and of anecdotes; are inquisitive, and desire information on every branch of natural knowledge. Individuality takes cognizance of things which are, the names of which are nouns; and eventuality, of things which happen, the names of which are verbs. The organ is situated in the middle of the forehead, and those in whom it is much developed have a peculiar prominence of this part of the skull.

31. Time. The faculty of time conceives the duration of phenomena, their simultaneousness or succession. Its organ is situated above the middle of the eye-brow.

32. Melody or Tune. The organ of tune bears the same relation to the ears as that of colour does to the eyes. The ear is the instrument by which sounds are heard, but it has no recollection of them, and does not judge of their relations; these are the offices of a peculiar and original mental power, whose organ is above the outer part of the eye-brow, so that when much developed, it enlarges the lower and lateral part of the forehead.

33. Language. This is the faculty which makes us acquainted with arbitrary signs, which remembers them, judges of their relations, and gives a disposition to indulge in all exercises connected with words. Its organ was the first that Dr. Gall discovered: in his youth he observed that while he had great difficulty in committing his lessons to memory, there were many boys who could easily learn by heart even things which they did not understand so well as he did. He noticed that all these boys were 'bull-eyed,' that is, had a peculiar prominence of the eye-ball, which seemed to project from its socket. Subsequent observation enabled him to confirm the opinion that the organ of verbal knowledge is situated at the very back part of the orbit, which is, with the eye, pushed forward by it when it is much developed.

34. Comparison is the reflective faculty which compares the sensations and ideas excited by all the other faculties, and points out their difference, analogy, similitude, or identity. It induces men to argue from analogy, to draw illustrations of their subjects from things well known, to speak by parables, and explain by examples and similes. It leads to the invention and employment of figurative language, and according to the degree of its national development, the language of each country will be full of or deficient in figures and metaphors. Its organ is situated in the middle of the upper part of the forehead.

35. Causality. The reflective faculty which engages men in the study of the causes and origins of things, and which guides to the employment of processes of induction, is thus named. The faculty of individuality makes us acquainted with objects; eventuality, with facts; comparison, with the analogy, identity, difference, and other relations of things; and causality leads us to search for their causes: together, these faculties, when fully developed, constitute the truly philosophic mind. The organ of causality is at the upper part of the forehead, on each side of comparison, and their coincident development gives the peculiar fullness of the front of the head, which is universally regarded as the sign of a powerful reasoning intellect.

Having now given a general view of the principles of phrenology, as stated in the writings of Dr. Spurzheim, and adopted by most of the present advocates of the system, it will probably be desirable to consider how far it is what it 'professes to be, a system of philosophy of the human mind, founded on the physiology of the brain.' (Combe, *System of Phrenology*, p. 1.) Neglecting for the present all metaphysical views of the subject, and regarding the theory of the existence of some such primary faculties of the mind as are assumed in phrenology, and of the dependence of each upon a separate portion of the brain, as one deserving of being tested by observation, we will examine only how far the doctrine, as it now stands, is supported by facts of anatomy and physiology, and whether it is capable of being established by the evidence of craniological investigation.

Many of the objections commonly made against phrenology are undoubtedly of little weight: such for example are the statements that in consequence of the irregularities of thickness in the coverings of the brain, it is impossible to determine its form by examination of the exterior. This objection only shows that there are sources of fallacy in the practice of craniology, a fact which no phrenologist denies. But on the greater part of the head, the differences of thickness of the coverings of the brain are not such as would lead into error; the majority of them are nearly constant in their amount, and are easily recognised by any one acquainted with the anatomy of the skull, and the rest are not sufficient to give that degree of elevation or depression to any part of the exterior of the head which would be regarded as indicative of excessive or deficient development of any organ. No one accustomed to post mortem examination can hesitate to admit that the form of the greater part of the exterior of the head corresponds as nearly with that of the surface of the brain as is necessary for craniological purposes. The parts in which the correspondence is often inexact are those over and in the neighbourhood of the eye-brows. The thickness of the superciliary ridge of the frontal bone is variable, and would certainly in some cases make a moderately developed organ appear large; and still more the size of the frontal sinuses (the cavities between the two plates of the frontal bone immediately above and by the sides of the root of the nose) must always be a source of fallacy in determining the size of that part of the adult brain in which the organs of form, individuality, size, and weight, and part of that of locality are supposed to be placed. The estimate of the supposed organ of language also, which is indicated by the prominence of the eye, must be liable to error from the varying quantity of the contents of the orbit. From these several circumstances however the utmost objection that can be raised is, that there must in general be some difficulty in determining the size of these few parts of the brain. In consequence of disease also the whole or parts of the brain may diminish in size without being accompanied by any corresponding change in the external form of the skull.[*] But as a general rule the subjects of disease are excluded in phrenological observations. The objection that parts of the brain have been destroyed without affecting any of the faculties of the mind is also of little weight, unless it be first proved that the organs are not double. The cases of this kind recorded before the promulgation of phrenology cannot fairly be deduced as evidence, because the statements which they contain relative to the preservation of the mental faculties after injuries of the brain, regard only the general powers of sensation, volition, memory, imagination, &c., and not the primary faculties of phrenologists, some of which might have been deficient without their loss being observed. The observations that have been made since, it must be confessed, are not of more weight against phrenology, than those of the loss of peculiar faculties (especially those of language and amativeness) by injury and disease of the brain are in its favour. Experimental mutilations of the brains of animals must be regarded as affording still less conclusive evidence; when a part of the brain is thus removed, the condition of the whole of the rest of its mass is altered by the removal of the pressure of the skull, exposure to the influence of the atmosphere, interference with the circulation of its blood, &c. It is impossible that a correct conclusion upon any part of the functions of the brain should be drawn from experiments of this kind; and the whole of the arguments deduced from them by Rudolphi, Magendie, and others, may therefore be neglected.

Fully admitting the insufficiency of these, as of some other minor objections to phrenology, we come to the consideration of some which must be regarded as more important. If phrenology were true, it might be expected that its applications would extend through the whole animal kingdom, and that according to the degree in which each mental faculty is developed in each animal, we should find a corresponding portion of its brain large or small when compared with that of man. Yet this is so far from being the case, that phrenologists are compelled to rest their opinions almost exclusively on evidence derived from the comparison of the brains of different individuals of the same species, and to suppose that though many faculties are the same in man and the lower animals, yet in each species they are manifested in some peculiar form and structure not admitting of comparison with those of man. This is evidently contrary to the analogical mode of reasoning which they pursue in other instances: all eyes, all ears, and all organs of smell are formed on the same principles, and so we might presume are all organs of the mind; so that as by the size or extent of distribution of their nerves we can determine in each animal the power of its sense of smell or sight or hearing, so by the size of a special part of the brain we might in each estimate the energy of some corresponding faculty. Between the vertebrate and the invertebrate animals, for example, there is an abrupt step in the condition of the nervous system; the brain and spinal chord of the lowest of the former class differ widely from the supra-œsophageal ganglion and the gangliated cords of the latter; we might therefore expect to find an equally sudden deterioration of mental power. Yet none such occurs: but although the supra-œsophageal ganglion (which may be regarded as the brain of insects) is only so much larger than the rest of their ganglia as is proportionate to the number of organs requiring to be supplied with nerves from it, yet none will deny that many insects exhibit more exalted psychical powers than the majority of either fish or reptiles do. But, taking the vertebrata alone, in all of which there is a certain general plan observed in the nervous system, it is not found that in each order or species, when compared with the rest, the parts of the brain are developed in proportion to the energy of the faculty ascribed to each of them. The phrenological function of the cerebellum, for example, is almost equally powerful in all species; yet the absolute and proportionate size of the cerebellum regularly lessens as one descends through the order of vertebrata, and in the batrachia, in which its supposed function is extremely energetic, it is a mere narrow cord passing across the fourth v[illegible]he part of the brain too, which is found decreasing as it is examined in the descending scale of vertebrate animals, is not the anterior, the seat of the intellectual faculties, but the posterior, in which are placed the organs of the animal propensities. A fair mode of comparison to determine this is to be found in the degree in which the hinder part of the cerebrum overlaps the cerebellum; in man alone does the former ever completely cover the latter; in idiots it often fails to do so; in monkeys it covers a still less portion; and continuing to descend through mammalia, the posterior lobes of the cerebrum grow constantly smaller, and the cerebellum is proportionally more, and at last completely, exposed. From these facts it might be assumed that the posterior lobes are the seat of some intellectual faculties; and such an assumption can be avoided only by believing that there is no analogy between the form of the posterior lobes of the cerebrum in man and mammalia. It is not denied that these apparent anomalies may exist, and yet phrenology may be true; but in balancing the probabilities of its truth or falsity, they must not be neglected.

The necessity which is felt of limiting the comparison of cerebral and psychical development to individuals of the same species[*] proves that some other condition than size is essential in determining the energy of each faculty, and that peculiarity of form and position of parts of the brain may give the external appearance of excess or deficiency of size; admissions which must throw doubt on the sufficiency of the only means which phrenology possesses of collecting facts to support its theory. If structure and form render it impossible by the size alone to determine the comparative psychical characters of two individuals of different species, the same conditions may often disturb the results that should proceed from comparisons of size in the organs of two of the same species.

In the limited field of the comparison of different individuals of the same species, phrenology is said by its supporters to be established by numberless facts of the correspondence of strength or weakness of each of the faculties with proportionate extent or deficiency of development of its organ; and they maintain that conclusions thus drawn from facts can be overthrown only by facts that contradict them.* But the numerous sources of fallacy which render the presumed facts for phrenology doubtful, present as great an obstacle to the collection of facts against it; and although its theory, which possesses so much plausibility, cannot be altogether overthrown by anything but well-ascertained facts, yet it is fair for any one to withhold his assent to it till he believes that it is supported by a sufficient number of positive and unerring observations; and the more so when he finds it opposed by some, however few, facts, and incapable of explaining several circumstances that might be expected to be placed under its laws. For these reasons the fallacies to which craniological observation is subject must be admitted as casting doubt upon the testimony of phrenologists, who, granting that they are unwilling to deceive, may yet, like all other observers, be charged with the liability to be themselves deceived. We believe that in this we do not step at all beyond the commonly adopted rules of judging from evidence, according to which it is open to every one to disbelieve statements and conclusions that seem to him improbable, although he may not be in a position to disprove them all by facts.

---

[*] It is commonly stated in phrenological works that as the brain diminishes in size the internal table of the skull grows inwards, increasing the thickness of the skull. The writer is convinced from numerous observations that the space left in the cavity of the skull by the diminution of the volume of the brain is in a large majority of instances filled up by an accumulation of fluid in the pia mater and in the ventricles [BRAIN]; and that the skull rarely undergoes any such change in its thickness as would be phrenologically important. Even when the whole, or, as is more rarely the case, a part of the skull does thus increase in thickness, it does not indicate that there was wasting of the parts of the brain immediately beneath it, but more frequently is consequent on a diminution of parts deeply situated, as the optic thalami and corpora striata. The examination of the skulls of those in whom particular organs are supposed to have wasted, must therefore be too fallacious to admit of any conclusions being drawn from them.

[*] Although, to meet the objections mentioned above, phrenologists insist on the necessity of comparing only individuals of the same species, it is to be observed that they readily make use of illustrations favourable to their opinions obtained by the contrary means, as for example in the determination of the organs of combativeness and destructiveness by a comparison of carnivorous and herbivorous animals, and of that of constructiveness by comparing the heads of the hare and the rabbit.

Judging by these rules, the very perfection to which phrenology is supposed to have nearly attained is strong evidence of its improbability. No one will deny that, in its connection with the body, the human mind must be the most difficult branch of physiology. Yet if phrenology be true, the physiology of the brain is more advanced than that of any other organ in the body; and the improbability is presented that two physiologists accomplished more in about 50 years of study of the most difficult branch of the science of life than the united generations of physiologists of all classes for near 2000 years have effected in the most easy. There is not one function of the living body which can be so perfectly illustrated by the most accomplished physiologist as (if phrenology be true) the functions of the mind can be elucidated by a mediocre adherent to its doctrines; and this too while, to every source of fallacy which it has in common with other departments of physiology, it is subject to still greater which are peculiar to itself.

The improbability that the labour bestowed upon phrenology should have had so extraordinary a result, will appear greater when some of the fallacies are pointed out to which the observations that serve for its basis are subject. Admitting that the size of a part of the brain may be taken as a measure of the power of the faculty of which it is presumed to be the organ, it can be a correct measure of power only when all other conditions are the same. This is admitted by phrenologists, who maintain only that, *cæteris paribus*, size is a measure of power; and it may be admitted that in this proposition they are supported by the analogy of other organs of the body. But in all of them, and therefore probably in the brain, the other conditions are fully as important as size; yet phrenologists in their usual practice refer to quality of the brain only when they find that the indications of quantity are manifestly opposed to their opinions. Moreover the estimate which phrenologists make of the quality of the brain, by observing the external appearance and temperament of the individual, is fallacious as a measure of the state of the whole mass, and is valueless as a sign of the structural condition of each of its several parts. But any one part of the brain may as well differ from the rest in quality as in quantity; an assumption which the phenomena of local diseases, which are much more common than general diseases of the brain, are sufficient to establish, and which phrenologists themselves admit in their explanation of monomania. There is here therefore a manifest source of fallacy in every phrenological observation; a source of fallacy comparable with, but greater than, most of those which have so long obscured the knowledge of the more simple departments of physiology. No one who has had any opportunity of appreciating the difficulty of analysing observations of which such a varying source of error as is here indicated forms a constant part, can avoid suspecting that phrenologists, when they pretend to have overcome the difficulty, have merely wandered into the facilities of error. Again, if the condition of quality (in which are included many important circumstances connected with both the temporary and permanent state of the brain, each of which is probably not less important than size) must be regarded as a constant source of inappreciable error in estimating the material condition of the organs, there is scarcely less fallibility in the other element of a phrenological observation, viz. the determination of the mental character of the individual examined. The actions of men are taken as the index to their phrenological state; but (not to mention the cases in which men feign the possession of dispositions and opinions which are not their own) it is evident that in numerous instances, in which there is no intention to deceive, the same actions proceed from different motives, and this phrenologists fully admit, for in many cases in which the size of certain parts of the brain does not agree with the apparent energy of the functions usually allotted to them, they refer the prominent actions of the individual under examination to the excess or defect of some other parts of the brain. But if in one case an apparent disagreement between the state of any faculty and of its presumed organ is thus easily capable of explanation by the condition of other faculties and organs, then in every case the state of all the other faculties must become an inappreciable source of fallacy in endeavouring to estimate the condition of any one.

It is unfair to make use of these supplemental modes of determining characters in cases that are opposed to phrenology, and not to admit their influence in those which seem favourable to it. If the actions of a man are to be taken as the index of his mind—but if at the same time it is allowed that the same actions may result from different propensities, desires, and tastes, it is evident that it will be almost impossible to bring the evidence of facts to bear against phrenology, in which there must then be so many facilities of escape from conviction of error. If, to take an illustration from the writings of Sir G. Mackenzie, a young man in whom locality and inhabitiveness are very moderately developed is yet irresistibly impelled to go to sea, by a mechanical genius, and by attachment to the mechanism of a ship, conjoined with perseverance, courage, love of approbation, and ideality, there can surely be no certainty that any one propensity is proportioned to the condition of a single organ rather than to the combined condition of several others.

When we point out these sources of fallacy in every phrenological observation that has been made, and add to them the doubt which is cast upon it by the total absence of any anatomical peculiarity in the brain correspondent with the presumed separation of its organs, and by the failure of its application in the comparison of the psychical condition of man and animals, sufficient has been done to show that a person exercises a justifiable and even a philosophical degree of caution in withholding his assent from phrenology as it at present stands. He may grant, as the writer does, that its theory is ingenious and probable; that its plan of classifying the faculties of the mind is probably more natural than that of any other psychological system; that the existence of many of the assumed faculties admits of little doubt; that a comparison of the heads of different nations and individuals renders it almost certain that the general divisions of the part of the human cerebrum are correct; that in many cases, on balancing the evidence on each side, the result is on the whole favourable to the belief that the positions of several of the organs in each part of the brain have been nearly determined; but without further and very extended inquiry, and that made with a just appreciation of the difficulties of attaining to facts, when so many of the elements of the observations are inappreciable, and conducted by a disposition to doubt rather than to find confirmation of the doctrine assumed, he will hesitate to accept its theory further than as a direction to his inquiries, and will refuse to admit its applications in any important practice.

PHRO'NIMA, Latreille's name for a genus of Amphipodous crustaceans.

Generic Character.—*Two* very short setaceous antennæ composed of a small number of joints. Four first feet (*mâchoires exterieures* of Latreille) in the form of small compressed arms, terminating in a point, and dentated below: the two interior the smallest, and annexed to the head. Fifth pair of feet largest of all, terminated by a didactylous claw. Six vesicular sacs divided into three pairs and placed at the internal base of the six last feet. Head very large, cordiform, and vertical. Body very soft, narrow, and long.

---

* Dr. Spurzheim and his followers constantly call upon the public to decide upon phrenology by their own observations; proving that they regard it no difficult matter to observe and draw correct conclusions in the most ambiguous questions of physiology. Upon this plan there is certainly no theory so absurd but it will easily gain adherents. One cannot feel assured that persons who are so little sensible of the difficulties of observation are themselves fully competent to observe. The more philosophic Dr. Gall did not fail to admonish his auditors not to attempt practising phrenology.

Tail more delicate than the body, terminated by six stylets (which are elongated and forked at the end), and provided below with four or six natatory feet disposed in pairs, under the third, fourth, and fifth rings; these feet being formed by a small joint for their articulation with the tail, of a large, oval, flattened joint, and two terminal filaments. (Desm.)

Examples, *Phronima sedentaria* and *Phronima Custos.*

The first (*Cancer sedentarius*, Forsk.; *Cancer gammarellus sedentarius*, Herbst.) has a transparent body, which is nacreous and dotted with reddish. Length not exceeding an inch.

Locality and Habits.—Lives at some distance from the coast, and keeps, according to M. Risso, in the interior of the body of *Radiata* belonging to the genera *Pyrosoma* and *Beröe.* Found in the Mediterranean and near Burray in Zetland.

Phronima Custos is smaller than the preceding, and very white. Found near Nice, in the interior of *Medusæ* (*Equorea* and *Geronia* of Péron and Lesueur). (Risso.)

PHRO'SINE, M. Risso's name for a genus belonging to the second section of *Amphipoda*, viz. those furnished with *four* antennæ.

Generic Character.—Two superior antennæ, large and spoon-shaped; two lower antennæ, setaceous and very small. The ten feet properly so called monodactyle, formed of five flattened joints: the first pair short, delicate, and hooked; the second a little shorter than the third; the fourth very large, with its first joint wide and oval, the two following triangular, the fourth oval and spiny, and the last long, pointed, arched, and falciform; the fifth pair shorter than the preceding, but of the same form. Body oblong, rather arched, somewhat rounded on the sides, with crustaceous transverse segments. Head prolonged in front in the form of a muzzle. Tail composed of five segments, which are nearly quadrangular, terminated by two oblong ciliated blades, and an intermediate short plate, which is flattened and rounded at the end. (Desm.)

Examples, *Phrosine semilunata* and *Phrosine macrophthalma.* The first has an oblong body, yellowish anteriorly, red posteriorly; the head is provided with two small horns, which form a sort of crescent; eyes small. Total length seven to eight lines.

Locality and Habits.—This species is rather rare in the neighbourhood of Nice, where it appears in the spring at the season of reproduction. Inhabits deeps on a sandy bottom. Eggs transparent.

Phrosine macrophthalma has an oblong violet-red body, with a transparent head; no horns; eyes very large, oval, and black; size less than half of that of the preceding species. Found by M. Risso on *Pyrosoma*, in February and July: at the latter period, the female is loaded with a quantity of very small globular eggs. (Risso.)

PHRYGIA (*Φρυγία*), a country of Asia Minor. It is difficult to define accurately the boundaries of Phrygia, as they differed at various times. Under the early Roman emperors it was bounded on the west by Caria, Lydia, and Mysia; on the north by Bithynia, on the east by Galatia and Cappadocia, and on the south by Lycia, Pisidia, and Lycaonia. Before the establishment of the province of Galatia by the Gauls, who invaded Asia Minor, Phrygia extended as far as the Halys. The antient writers speak of the Great and the Lesser Phrygia; but when Phrygia is spoken of by itself, the former is always intended, as the latter was only a political division, and was included in Mysia, which was inhabited by several Phrygian tribes. The northern part of Phrygia Proper was called Phrygia Epictetus, or the 'Acquired,' a name given to it when it was annexed by the Romans to the kingdom of Pergamos (Strabo, xii. 567); and the southern part, which bordered upon Mount Taurus, was called Phrygia Paroreius from this circumstance. In the fourth century the Romans divided Phrygia into two provinces, Phrygia Salutaris and Phrygia Pacatiana; the former comprising the eastern and the latter the western part of the antient province.

Phrygia is a high table-land, supported on the south by Mount Taurus, and on the north by the high range of mountains which runs from west to east under the antient names of Ida and Temnon in Mysia, and Olympus in the neighbourhood of Brusa. Herodotus says (v. 49) that Phrygia is exceedingly fertile; but this remark must be applied only to the western and northern parts of the province, since the country in the southern and eastern parts is covered with salt marshes, rivers, and lakes, which have no visible outlet. Of these salt lakes, the most curious is the one called Tatta by Strabo (*Tuzla*), which is 30 miles in length, and supplies a vast tract of country with salt. [Anatolia, p. 494.]

The Phrygians are said to have been a very antient people. According to a ridiculous tale told to Herodotus in Egypt, Psammitichus, king of Egypt, made an experiment, by which he ascertained that the Phrygians were the most antient people in existence. (Herod., ii. 2.) Herodotus says in another part of his work (vii. 73), on the authority of the Macedonians, that the Phrygians were a European people, and originally dwelt in Macedonia, where they were called Briges, which account is also given by Strabo (vii. 295). They are said by Conon (*apud* Phot.) to have passed over into Asia a hundred years before the Trojan war. Xanthus says (*apud* Strab., xiv. 680) that they emigrated from Europe subsequently to the Trojan war; but, as Strabo remarks, this could not have been the case, as they are represented by Homer (*Il.*, iii. 187) as settled on the banks of the Sangarius before that period.

We know scarcely anything of the early history of Phrygia. There appears to have been a kingdom of considerable power in the northern part of Phrygia under the Midian or Gordian dynasty. Strabo remarks (xii. 568) that the palaces of Gordius and Midas were near the river Sangarius, the neighbourhood of which was probably the central part of the dominions of these sovereigns; and that such was the case is confirmed by an antient inscription discovered at Doganlu by Colonel Leake, in which we find written in Greek, 'To King Midas.' (Leake's *Tour in Asia Minor*, p. 31.) The first of this dynasty of whom we have any authentic account is Midas, the son of Gordius, who was the first of the barbarians who sent offerings to Delphi. (Herod., i. 14.) As Herodotus says that these offerings were earlier than those of Gyges, king of Lydia, Midas must have reigned before B.C. 718. The Phrygians were conquered by Crœsus and added to the Lydian empire (Herod., i. 28), and were subsequently subject to the Persians. (Herod., iii. 90.) On the division of Alexander's dominions, Phrygia first came into the hands of Antigonus, and afterwards formed part of the dominions of the Seleucidæ. After the defeat of Antiochus the Great, Phrygia was given to Eumenes, king of Pergamos, and on the death of Attalus, B.C. 133, it came by his bequest into the hands of the Romans, together with the other dominions of the kings of Pergamos. [Pergamos.]

In Northern Phrygia, the first town of importance on the west was Azani, near the source of the Rhyndacus (*Lubod*), which flows into the lake Apolloniatis. This town is not often mentioned by the antient writers, but it must have been a place of considerable importance, from the description of its ruins given by Major Keppel, who says that the modern village of Tjandere Hessar is entirely built out of them. S.E. of Azani was Cotyæium, or Cotyæum (*Kutaya*), on the Thymbrius, which is still a considerable place. North of Cotyæium and also on the Thymbrius, at no great distance from its union with the Sangarius, was Dorylæum. (Strabo, xii. 576.) This town is alluded to by Cicero (*Pro Flacco*, 17), and is said by Athenæus (ii. 43. Casaubon) to have possessed some warm springs in its neighbourhood. Colonel Leake (p. 18) supposes it to correspond to the modern town of Eski-shehr, which is celebrated for its natural hot baths. Dorylæum is often spoken of by the Byzantine historians. East of Dorylæum was Midæum, also in Phrygia Epictetus (Strabo, xii. 576), which was originally one of the royal cities of the antient kings of Phrygia. (Strabo, xii. 568.) South of Dorylæum was Nacoleia, which is frequently mentioned by the later writers. Colonel Leake (p. 24) thinks that Nacoleia corresponds to the modern village of Pismesh Kalesi, near the valley of Doganlu, where he discovered some very remarkable monuments, which he supposes to have been the sepulchres of the antient kings of Phrygia. The Phrygian Ancyra [Ancyra] is conjectured by Mr. Hamilton (*London Geog. Journ.*, vol. viii.) to have been at Kilíseh Köï, at the western extremity of the lake of Simáwul.

In the south-eastern part of Phrygia was Synnada, one of the most important towns of this part of the province in the time of Pliny, who says (*Hist. Nat.*, v. 29) that it was a conventus juridicus for all the surrounding towns. Strabo however says (xii. 577) that it was not a large town, and that it was situated at the end of a plain sixty stadia long, and planted with olives. It was a place of considerable commerce and traffic, as it was situated on the road from

Apameia Cibotus to Galatia (Liv., xxxviii. 15), and also in the way, or nearly so, from Apameia to Iconium and Cilicia. (Cic. *ad Att.*, v. 20; *ad Famil.*, xv. 4.) Colonel Leake (p. 54) thinks that the site of Synnada corresponds nearly to the modern village of Buiwudun. At a short distance to the north of Synnada was Docimia, which was celebrated for its marble quarries. It was of a light colour, interspersed with purple spots and veins, and was in great request among the Romans. (Strabo, xii. 577; Stat., *Silv*, i. 5, 37; Plin., *Hist. Nat.*, xxxv. 1.)

The most important cities in Phrygia were situated in the south-western part of the province. Of these cities Celænæ was the most antient. Herodotus says (vii. 56) that it is situated at the source of the river Mæander, and also of the Catarrhactes, a stream not less than the Mæander. The Catarrhactes appears to be the same as the Marsyas of Xenophon (Xen., *Anab.*, i. 2, § 7) and other writers. Xerxes, after his defeat in Greece, is said to have built here the citadel and a palace (Xen., *Anab.*, i. 2, § 9). The younger Cyrus appears to have frequently resided at Celænæ, where he had a palace and a great park full of wild beasts. Celænæ was celebrated in Grecian mythology for the contest between Apollo and Marsyas. Xenophon says that Apollo hung up the skin of Marsyas in the cave whence the river flows. Near Celænæ was Apameia Cibotus, which was founded by Antiochus Soter, who removed to the new city the greater part of the inhabitants of Celænæ, which became in consequence a place of small importance. Antiochus gave it the name of Apamea, from his mother Apama, who was the daughter of Artabazus and the wife at that time of Seleucus Nicator. (Strabo, xii., p. 578; Liv., xxxviii. 13.) Apamea soon became a place of great wealth, and in the time of Strabo was second only to Ephesus in Asia Minor in commercial importance. Pliny says (*Hist. Nat.*, v. 29) that it was the capital of a conventus. There has been considerable doubt respecting the site of Apamea, but it appears, from the testimony of Pococke, Mr. Arundell, and Colonel Leake, to have been at a place called Dinglar or Dunare.

South-west of Apamea, and a little to the south of the river Lycus, was Colossæ, which is mentioned by Herodotus (vii. 30) and Xenophon (*Anab.*, i. 2, § 6) as a large and flourishing city. Strabo (xii. 576) and Pliny (v. 29) however speak of it as only a small place. At Colossæ there was formed a Christian church, chiefly, it appears, by the labours of Epaphras (*Col.*, i. 7; iv. 12, 13), to which St. Paul, who does not appear to have ever visited Colossæ himself (*Col.*, ii. 1), wrote an epistle. Colossæ was destroyed by an earthquake, together with Hierapolis and Laodicea, in the ninth year of the reign of Nero (Oros., vii. 7), but was built again, and became in the middle ages a place of considerable importance under the name of Chonæ. Chonos is at present a small village, situated under a very high hill; the ruins of the antient city may be traced for nearly a mile. (Arundell's *Visit to the Seven Churches*, p. 94-98.)

West of Colossæ, and a little to the south of the Lycus, was Laodicea, which was a large commercial town in the time of Cicero (*Ad Fam.*, ii. 17; iii. 5) and Strabo (xii., p. 576). Pliny (v. 29) says that it was originally called Diospolis, and afterwards Rhoas; and we learn from Stephanus Byzantinus that its name was changed into Laodicea in honour of Laodice, the wife of Antiochus II. There was a Christian church at Laodicea in the time of the Apostles. St. Paul speaks of this church in his epistle to the Colossians (ii. 1; iv. 16); and St. John, in the book of the Revelation (iii. 14-16), rebukes its members for their lukewarmness in the cause of the gospel. Strabo says that Laodicea was celebrated for the sheep which fed in the plains around it, and that their wool was considered superior to that of Miletus. The ruins of Laodicea, which are considerable, are seen a little below Denisli.

Nearly opposite Laodicea, to the north of the Lycus, was Hierapolis, which was celebrated for its mineral springs. (Strabo, xiii. 629.) The ruins of Hierapolis, according to Chandler (*Travels in Asia Minor*, p. 290), are on the site called Pambouk-kalessi, and are about a mile in length. There are remains of a very large theatre and of other public buildings.

PHRYGIAN MODE, in antient Greek music. [Mode.]

PHRY'NICHUS. Several persons of this name are mentioned by Suidas and others.

Phrynichus of Athens, the son of Polyphradmon, was a disciple of Thespis, and a writer of tragedy. He was upwards of twenty years the contemporary of Æschylus, and probably he was about so many years his senior. The titles of fourteen tragedies of Phrynichus occur, of which five have been supposed to be the productions of another Phrynichus, the son of Melanthas: but Bentley has clearly proved that this supposition is without any foundation, and that there was only one tragic poet of this name.

Phrynichus first exhibited B.C. 511, and he gained the prize for his 'Phœnician Women' (*Φοινισσαί*) B.C. 476, the subject of which was drawn from contemporary history, being the victories of Athens in the Persian wars. It appears from these dates that he was a dramatic writer during thirty-five years, but we know not the time either of his birth or his death.

Phrynichus effected a great improvement in the tragedy which Thespis had introduced. He no longer sanctioned the ludicrous diversion in which Bacchus and the Satyrs only were personated; but he derived the subjects of his plays from the graver parts of the mythology and history of his country. With the example of Æschylus to stimulate him, he made still further advances. One of his tragedies, 'The Capture of Miletus' (*Μιλήτου ἅλωσις*), referring to an event which took place B.C. 494, five years after Æschylus won his first prize, is particularly mentioned by Herodotus (vi. 21). He relates that the poet melted the spectators into tears by his vivid picture of the sufferings of their Ionian brethren. It may be presumed that his 'Phœnissæ,' which won the prize B.C. 476, was marked by equal if not superior excellence. Aristophanes on several occasions brings in the name of Phrynichus in such a way as to show that he was esteemed a poet of no ordinary powers.

But Phrynichus did not invent the dialogue; he had only one actor, at least until Æschylus introduced the dialogue; the choral ode still constituted the chief part of the performance. The improvement of first adding the dialogue and shortening the chorus is due to Æschylus; Phrynichus first introduced female parts. No fragments of Phrynichus are extant. (Suidas, *Lexicon*; Bentley's *Phalaris*; Müller's *Hist. of Greek Literature*.)

Phrynichus of Athens, a comic poet, who flourished B.C. 430. Ten comedies of his are mentioned by antient writers. (Suidas; Bentley.) A few fragments of this poet have been collected by Hertelius and Grotius. He is once quoted by the Phrynichus who forms the subject of the next article.

Phrynichus (called Arrhabius by Photius; and by Suidas, the Sophist of Bithynia), flourished under the emperors M. Aurelius and Commodus, from A.D. 170 to 190. He has left a work entitled 'A Selection of Attic Verbs and Nouns' (*ἐκλογὴ ᾽Αττικῶν ῥημάτων καὶ ὀνομάτων*), the object of which is to point out the proper use of certain words, and of certain forms of words, as alone authorised by the writers of pure Attic diction. This work has been several times printed. The best edition is that of Lobeck, 8vo., Leipzig, 1820, which contains the substance of all the annotations of the preceding editions, and is enriched with many original remarks. A fragment of Herodian, the grammarian, upon the same subject, accompanies the work of Phrynichus. Lobeck has added six dissertations (which he calls Parerga, in six chapters), suggested by his investigations in editing Phrynichus. These dissertations exhibit deep learning and sound criticism, and are of great value independently of their relation to Phrynichus. Four indexes conclude the volume, which is extended to 841 pages, besides eighty pages of preliminary matter. (Photius; Suidas; Fabricius.)

PHTHISIS (a Greek word, *φθίσις*, signifying 'corruption,' 'decay') was formerly used as a generic term to signify a wasting or consumption from any cause, and was afterwards more distinctly specified, according to the organ in which it was supposed to originate: hence we had a Phthisis Hepatica, P. Mesenterica, P. Pulmonalis, &c.; but the word is now restricted to the disease produced by tubercles in the lungs, and commonly known by the name of consumption. An acquaintance with this disease, from which neither age nor sex is exempt, and no part of the habitable globe is free, whose ravages extend even to the brute creation, and whose course when once begun can rarely be stayed, whose commencement is frequently so insidious, and whose termination so fatal, must, above all others, be interesting; for if by any precautions its development can be prevented, it is only by a knowledge of those influences which most frequently give rise to it that we can hope to attain our object.

Morbid Anatomy of Phthisis.—The local morbid changes peculiar to Phthisis are only the result of previous changes in the general system, an hereditary or acquired predisposition, cognizable by the physical condition of the patient, and by a disordered state of various functions; 'and which, though very generally accompanied with a feeble organization, is not inconsistent with too great development and inordinate action of particular parts, and even with considerable physical power of the system.' By far the most important and characteristic morbid change that occurs in Phthisis consists in the development of tubercles wherever they may be found; but as it is in the lungs that they first and most frequently manifest themselves, we shall describe them as they are seen in those organs. Tubercles of the lungs first appear in the form of small, grey, semi-transparent granulations, which gradually enlarge and become opake in their centre: the opacity increases, till the whole mass becomes of a dull yellowish-white colour. After a certain time they soften, empty themselves into the bronchial tubes, and give rise to excavations more or less considerable. In this way, almost the whole of both lungs may be invaded by a succession of tubercles, their healthy structure being absorbed as the tubercles become deposited, or involved in the destructive process consequent upon their softening. Tubercles, unlike inflammation, almost invariably commence at the summit of the lungs, where, as well as being more numerous, they are usually found in a more advanced stage of development than in any other part. The successive eruption of fresh tubercles is an important feature in this disease, as it explains the occasional recovery of patients labouring under consumption.' A crop of tubercles may appear in the lungs, go through the various stages above described, and give rise to all the symptoms of confirmed Phthisis; yet provided the conditions which gave rise to them are removed, no fresh eruption may take place, and the patient shall recover. The relative frequency of tubercles in other organs differs considerably in the adult and in the infant. In the former, M. Louis, our greatest authority in all matters connected with Phthisis, has, with one exception, never observed them in any organ without their existing in the lungs; so that he regards their presence in these last viscera as a necessary condition for their development in other parts. But in the infant this does not appear to hold good; the bronchial glands being more frequently affected than the lungs, in the proportion of 87 to 73. The brain and its membranes are likewise more subject to tuberculous deposits in the child than in the adult. The next most important lesion which is met with in phthisis is ulceration of the intestinal canal. The ulcers may vary in number, form, and size, but they all present specific characters peculiar to this disease and to no other, and exist in five-sixths of the cases which terminate fatally. The third peculiarity in reference to phthisis is the change that the liver undergoes; to which the French pathologists have given the name of 'Foie Gras,' or fatty liver. Lastly, ulcerations of the epiglottis, larynx, and trachea occur so frequently, and with such uniformity of type, as justly to lead to the belief that they are a part of the disease. But besides these morbid changes, which are peculiar to this disease, complications of various kinds occur which are common to it and other chronic diseases. By far the most frequent of these are inflammations of the Pleuræ; so that it is extremely rare, in making the post mortem examinations of persons who die of phthisis, not to find the lungs adherent, in part, or entirely, to the walls of the chest. Inflammation of the substance of the lungs is likewise a frequent complication in the latter stages of phthisis.

Symptoms of Phthisis.—These generally commence with a slight cough, which at first excites no attention, but is regarded as a simple cold. The breathing is not seriously affected, nor is the appetite impaired. After a time the cough increases in frequency, and is accompanied by expectoration of a clear frothy saliva: the breathing and pulse become a little hurried after meals and towards evening; and at this time of the day there is frequently experienced a slight degree of chilliness, followed by heat, which continues during the greater part of the night, and is succeeded towards morning by perspiration. The patient likewise becomes somewhat paler, and is languid and easily fatigued. In some instances the first symptoms are preceded by a more or less copious hæmoptysis. In the second stage of Phthisis the cough becomes more frequent, especially during the night, and if violent, it sometimes occasions vomiting; hoarseness, or loss of voice, is not unusual: the expectoration changes its character; it is less frothy, and more opake; containing small particles of a yellowish curd-like substance; or the sputa are streaked with dull yellow lines; and hæmoptysis is pretty frequent, but in general not abundant; the breathing and pulse are more hurried: the fever is greater; and the perspirations more regular and copious. pains in the thorax, denoting pleuritic inflammation, often occur; and the languor and emaciation still increase. In the last stage of consumption there is nearly always profuse diarrhœa, and the sweats and expectoration are more copious: the latter becomes more uniform in composition, and is separated into roundish distinct masses, with flocculent edges. The emaciation and debility keep pace with the other symptoms; and the feet and ankles swell towards evening: the appetite generally declines in the same proportion, and the patient dies in the extreme degree of marasmus, not unfrequently flattering himself to the last with a speedy recovery. In females the menstrual discharge almost always ceases when hectic fever is established; and occasionally even before that is the case, which has led to a popular opinion that the disease in such cases arises from the suppression. Such are the ordinary symptoms presented by Phthisis in its most usual form; but varieties exist in the order and duration of the morbid phenomena. Thus, tubercles may be developed in the lungs, and remain for a considerable period without exciting either cough or expectoration, or even any important general symptoms. In other cases they give rise to intense general symptoms; as fever, emaciation, anorexia, before they excite cough or expectoration; the latter appearing only a short time previous to death. To these cases the term *Latent Phthisis* has been applied; and what is remarkable in them is, the absence of appreciable organic alteration in organs whose functional derangement was most violent; while the only viscus really affected seems functionally healthy. The term *Acute Phthisis* is applied to those cases in which the disease goes through all its stages with unusual rapidity. It occurs most frequently in the young, and in those weakened by some previous disorder. In popular language it is designated galloping consumption. *Chronic Phthisis* is the reverse of the last, and comprehends all those cases in which the progress of the disease is unusually slow and generally intermittent.

Diagnosis of Phthisis.—Auscultation and percussion are the chief means by which we arrive at the diagnosis of phthisis [AUSCULTATION; PERCUSSION]; but there are several collateral circumstances which must be taken into consideration in order to form a correct opinion as to the nature of the disease. It is at the commencement of phthisis that an accurate diagnosis is of most importance, and in which the stethoscopic signs are least evident. We shall be therefore more particular in enumerating the indications at this period, than in accurately describing the acoustic phenomena which are present at a more advanced stage of the disorder. As bronchitis is the disease with which phthisis is most liable to be confounded, we shall place in juxtaposition the principal points in which they differ. In the greater number of cases of phthisis the cough comes on without any evident cause, and many months may elapse without expectoration. This apparent absence of cause and dryness of cough are of themselves very remarkable, and differ from what occurs in simple bronchitis. Thoracic pains, when present in the latter affection, are generally felt in the middle of the sternum; while in phthisis they are situated in the sides of the chest and between the shoulders. Hæmoptysis, from the commencement or during the progress of cough, is frequent in phthisis, and is almost a certain sign of the presence of tubercles; whereas this symptom never occurs in bronchitis. Out of twelve hundred patients affected with various diseases, not including cases of amenorrhœa or those arising from external violence, M. Louis found that not one, with the exception of phthisical cases, had experienced this symptom. Auscultation gives us little or no aid in the earliest stages of phthisis, and when the stethoscopic signs first manifest themselves, they are such as result from an increased density in the structure of the lung, and not from the presence of fluid in the bronchi, as is the case in bronchitis. Thus the expiration, which in health is scarcely audible, becomes more distinct; the voice more resonant; the sound elicited on percussion duller. These alterations in the respiration and in the signs produced by percussion, like the development of tubercles, take place from the summit to the base of the chest; and at first are almost constantly confined to the upper lobe of one side In bronchitis the sounds result from fluid in the bronchi, and originate in the lower part of the chest, and usually on both sides. In the more advanced stages of phthisis its diagnosis is less difficult, and is made from a consideration of the sputa, which we have already described, and from the signs furnished by percussion and auscultation. These are now decisive; the upper parts of the chest are dull on percussion; the respiratory murmur is strong, coarse, or even cavernous under the clavicles; and the voice listened to in the same situation gives rise to that peculiar phenomenon termed pectoriloquy. If there should be much fluid in the lungs, resulting from the patient's not having lately expectorated, we then have a mucous rattle in all those parts of the chest corresponding with the seat of the disease; and where cavities containing fluid exist, the air passing through this produces that gurgling noise to which the term gargouillement has been applied by the French. The space in which these different changes take place is at first limited; but it daily increases, and in some instances, where the entire upper lobe of the lung is converted into numerous excavations, the respiration is coarse and more or less tracheal throughout its whole extent. The diagnosis of latent phthisis is not difficult, provided we make use of the proper means for ascertaining the condition of the pulmonary organs; the evil is, that the attention is directed exclusively to those functional derangements which we have spoken of when describing latent phthisis, while the real seat of the disease is overlooked.

Duration and Mortality of Phthisis.—Various circumstances affect the duration of phthisis, as age, sex, constitution, occupation, season of the year, climate, &c. In the upper ranks of life, where patients have all the advantages that a proper regimen, change of air, and good medical treatment can afford, the average duration of the disease is considerably above that exhibited in the table below.

	114	200	114 + 200	=314

The mean duration of 314 cases exhibited by this table is 23 months, including the extreme cases; but 162, or more than half of the cases, terminated in 9 months; and the greater proportion of them between the fourth and ninth month. By excluding those cases which terminate within four months, and those that exceed four years, the average duration of the remaining cases is eighteen months. With regard to the mortality from phthisis, it varies in different climates, ages, sexes, races, and occupations. In England and Wales, according to the 'Report of the Registrar-General of Births, Deaths, and Marriages,' lately published, it is 19·55 per cent. of the total number of deaths, or 3·82 annually out of 1000 living. In France it is about the same. On the eastern frontiers of the Cape of Good Hope, where the atmospheric vicissitudes are sudden and great, the thermometer in summer sometimes varying from 110° to 64°, and in winter from 75° to 32° in the course of a few hours, it is only $3\frac{1}{4}$. Premising that a greater number suffer from phthisis among the military than the civil population, the following table, from Major Tulloch's 'Statistical Reports,' shows the number of men attacked annually by phthisis out of 1000 of white troops, at each of the following stations:—

	Windward and Leeward Command.	Jamaica.	Gibraltar.	Malta.	Ionian Islands.	Bermuda.	Canada.	Nova Scotia and New Brunswick.	Cape District.	Mauritius.	United Kingdom.
Attacked annually by Phthisis out of 1000 white troops at each of the following stations.	12	13	$6\frac{5}{10}$	$6\frac{7}{10}$	$5\frac{2}{10}$	$8\frac{8}{10}$	$6\frac{5}{10}$	7	$3\frac{1}{3}$	$7\frac{7}{10}$	$6\frac{6}{10}$
Deaths annually per 1000 from all diseases of the lungs at the same stations.	$10\frac{4}{10}$	$7\frac{5}{10}$	$5\frac{3}{10}$	6	$4\frac{8}{10}$	$8\frac{7}{10}$	$6\frac{7}{10}$	$7\frac{1}{10}$	$3\frac{9}{10}$	$5\frac{6}{10}$	8

In the perusal of this table it must be borne in mind that the total mortality from all diseases of the lungs in the foreign stations appears to be less than it really is. This arises from many of the patients being invalided, who, if they die on their passage home, or after their arrival in Britain, are not included in the returns of the station where their diseases originated.

It may here be interesting to compare the influence of this class of diseases throughout the different stations where negro troops have been employed:—

	West Coast of Africa.	Honduras.	Bahamas.	Jamaica.	Mauritius.	Windward and Leeward Command.	Gibraltar.
Died annually per 1000 by diseases of the lungs in Black troops.	$6\frac{3}{10}$	$8\frac{1}{10}$	$9\frac{7}{10}$	$10\frac{3}{10}$	$12\frac{9}{10}$	$16\frac{6}{10}$	$33\frac{6}{10}$

Nearly two-thirds of this mortality arise from consumption. Thus, in his native country the negro appears to suffer from these diseases in a less proportion than British troops in their native country; but so soon as he goes beyond it the mortality increases, till in some colonies it attains to such a height as seems to preclude the possibility of his race ever forming a healthy or increasing population. The Hottentots in our army at the Cape of Good Hope suffer more from diseases of the lungs generally than the European troops; while the proportion of those who die from phthisis is about the same. In both cases the mortality is below the average, as is seen in the table before referred to.

The natives of some tropical climates seem so little subject to diseases of the lungs, that among 74,850 native troops serving in the Madras presidency, the deaths, by every description of disease of the lungs, did not, on the average of five years, exceed one per 1000 of the strength annually.

The period of life above puberty at which the greatest mortality from phthisis occurs is between 20 and 40, as will be seen by the following table; and it is worthy of remark that although the number of deaths from phthisis is more considerable from 20 to 40 than from 40 to 60, the general mortality is less in the first than in the second period.

Died of phthisis at the following ages:—

Age.	Deaths.		
	Louis.	Bayle.	Total.
15 to 20	11	10	= 21
20 30	39	23	= 62
30 40	33	23	= 56
40 50	23	21	= 44
50 60	12	15	= 27
60 70	5	8	= 13

In respect of sex, consumption destroys more females than males, in the ratio of 4·155 to 3·771. This includes the whole of England and Wales, but does not hold good as regards some cities and most of the mining districts. In these the pursuits of a large portion of the male population seem particularly inimical to health, and raise the mortality from phthisis nearly to what it is in the female, and in some places even above, as will be seen in the following abstract from the Registrar-General's Report:—

Died of phthisis from July 1st to December 31st, 1837, in the metropolis, whose estimated population on the 1st of October, 1837, was 1,790,451, and in the unions of the counties of Cornwall, Devonshire, Dorsetshire, Somersetshire, and Wiltshire, whose estimated population at the same period was 1,723,770—

Males.		Females.	
Metropolis.	Counties.	Metropolis.	Counties.
1947	1325	1930	1466

Died of phthisis from July 1st to December 31st, 1837, in the counties of Essex, Gloucester (except Bristol and Clifton), Hereford, Norfolk (except Norwich), Suffolk, Sussex, and Westmoreland, whose estimated population on the 1st of October, 1837, was 1,776,980; and in the districts of Aston, Bath, Birmingham, Bristol, Cambridge, Carlisle, Clifton, Derby, Dudley, Exeter, Leeds, Leicester, Liverpool, Manchester, Maidstone, Newcastle-on-Tyne, Northampton, Nottingham, Salford, Sheffield, Stoke-on-Trent, Sunderland, Wolverhampton, and West Derby, whose estimated population at the same period was 1,762,710—

Males.		Females.	
Cities.	Counties.	Cities.	Counties.
2118	1363	2130	1703

These tables point out generally the influence of occupation in the production of phthisis. In cities the majority of the male labouring population is engaged in the arts, trades, and manufactures, and generally for many hours together in ill-ventilated apartments, and in unhealthy postures of body. In the country the pursuits of the same class of persons are chiefly agricultural.

Having now considered the mortality of phthisis in connection with climate, race, age, sex, and occupation, we are enabled with greater advantage to examine into those causes which appear to be most active in its production.

Causes of Phthisis.—The causes of phthisis, says Sir J. Clarke, may be divided into 'the remote and the exciting, or those which induce the constitutional predisposition, and those which determine the local deposition of tuberculous matter after such predisposition is established. The one class of causes operates by modifying the whole system; the other, by determining in a system so modified the particular morbid action of which tuberculous matter is the product.' Of the remote causes, or those which induce the constitutional predisposition, perhaps the most powerful is that which arises from hereditary transmission; not that an individual born of consumptive parents will himself necessarily fall a prey to the same disease, but only that, when exposed to those influences which we are about to enumerate as determining the tuberculous cachexia, he will be more likely to become affected than one born of healthy parents. Next to hereditary transmission of the consumptive diathesis, the causes most active in producing this state of constitution are, a sedentary life, more especially when associated with a confined posture of the body and impure air; bad quality or insufficient quantity of food; insufficient clothing; excessive mental or bodily labour; mental depression; and abuse of spirituous liquors. In fact, all those agents which operate in depressing or lowering the tone of the system generally act as remote causes in the production of phthisis. The more immediate or exciting causes of consumption, those which determine the deposition of tubercles, have usually been attributed to irritants acting locally on the bronchial tubes or on the lungs, whether occasioned by inflammation of these parts or by the mechanical action of irritating bodies upon them. The result of the latest investigations on this subject leave no doubt that the influence exerted in this way has been greatly exaggerated. Pneumonia and bronchitis, the two diseases hitherto regarded as the most frequent forerunners and producers of phthisis, have been shown by M. Louis to exert no more influence in its production than any other disease. They may indeed occasionally hasten the development of tubercles, but they exert no specific effect, and they act only as remote causes in impairing the health generally. These conclusions of Louis, which have been deduced from his own observations in hospital practice solely, receive ample confirmation from the admirable Statistical Reports of the Registrar-General and Major Tulloch, which we have before referred to. The popular error of attributing consumption to cold, the breaking of a blood-vessel, &c., has probably originated from mistaking the effect for the cause. We have shown in a former part of this article that cough and hæmoptysis are among the earliest symptoms of tuberculous lungs. With regard to mechanical irritants, as dust of various kinds, noxious gases, smoke, &c., 'no opinion has been more prevalent,' observes Dr. Cowan, 'than that those who are exposed to the inhalation of the dust of vegetable, mineral, or animal substances, are peculiarly liable to phthisis; and in the supposition that consumption was essentially a disease of the lungs, and in the great majority of instances the result of bronchial inflammation, no conclusion was more natural or more probable. But once remove from the mind the impression of a necessary connection between bronchitis and tubercles, and we feel persuaded that the examination of the evidence brought forward on the subject of dust will terminate in the conviction that this agent exerts at most but a very secondary and unimportant influence in the production of phthisis.' The mortality among the workmen in some of our manufacturing towns is usually brought forward in support of the doctrine of mechanical irritation. Dr. Knight of Sheffield informs us that there is not an example of a polisher of forks reaching his 36th year, nor do the artisans in other departments attain a much greater age. But it must be recollected that many of these men work sixteen hours a day in a close atmosphere and confined posture of body, two conditions which contribute perhaps more than any other to the increase and production of phthisis. Nor has the mortality been diminished by the use of magnets, wire masks, currents of air, and moisture, which have been successively tried for the purpose of arresting the metallic particles. In the cases of 887 quarrymen, 557 stone-cutters, and 160 marble-workers, all of them occupations involving the inhalation of dust, M. Benoiston found the proportion of phthisis was less than the general average; but then these are employments carried on in the open air. Dr. Lombard, whose researches are founded on a total of 4300 deaths from phthisis, and 54,572 individuals, exercising 220 different occupations, found, by a comparison of all the professions carried on in the open air and in workshops, that the proportion of deaths from phthisis was *double* among the latter; and this proportion increased as the apartments were close, narrow, and imperfectly ventilated.

Mr. Watson, a surgeon of Wenlockhead, a mining district, informs us that, out of 74 men working during four or five months for sixteen hours daily in a mine where a candle burnt with difficulty, not one was attacked with any pulmonary affection. But whether from the inhalation of noxious gases or from other causes, it is certain that in the majority of the mining districts of this country the mortality from phthisis is high. The number of males attacked by this disease in Cornwall exceeds that of the females in the ratio of 170 to 140, and in the mining parts of Staffordshire, Shropshire, and Worcester, in the ratio of 203 to 191; while in the non-mining districts of Staffordshire and Shropshire, and in the county of Cheshire, the ratio is 656 males to 796 females.

The influence of smoke, when uncombined with other agents of injurious tendency, may, we think, fairly be called in question. In Leeds, which is certainly the most smoky place in the whole kingdom, the mortality of females from phthisis is below that of most of our large manufacturing towns, and is not much above the average for the whole of England and Wales. In London likewise this is the case, and in nearly the same proportion, as will be seen in the following table of the relative mortality of females from phthisis in each of the under-mentioned cities, and in England and Wales:—

Annual Deaths to 100,000 *living.*

Leeds.	Birmingham.	Manchester.	London.	Liverpool.	England and Wales.
401	494	510	402	670	386

It must not be forgotten that in these towns a large proportion of the female sex is occupied in those kinds of employment that we have before shown to be so prejudicial: how much then must be attributed to the smoke, if the unhealthy occupation were expunged from the account? From what we have advanced against the operation of local irritants as causes of pulmonary consumption, we by no means wish to be understood as deprecating the use of any means calculated to get rid of this source of irritation; but we merely propose to show that they act a very inferior part, and, when unassociated with those circumstances which modify the system in general, their real activity as causes of pulmonary tubercles is problematical. It would not however be fair to omit the mention of one fact, which in truth is the only one that we have met with, in evidence of a direct local irritation giving rise to tubercles. This fact is related by the late Baron Dupuytren. A boy was brought into the Hôtel Dieu for some surgical complaint, of which he died. On examining the body after death, a marble was found impacted in one of the bronchi; around this spot, but in no other part of the body, was found a small crop of tubercles.

A moist and changeable climate has been regarded hitherto as among the most active causes of consumption; and Great Britain, whose climate combines these two conditions in a remarkable degree, has been looked upon as such a nursery for phthisis, that our facetious neighbours on the other side of the Channel have styled it 'La Maladie Anglaise.' Indeed the notions of atmospheric vicissitudes, dampness, and consumption, seem almost inseparable. However, these opinions have been and still are undergoing a severe scrutiny; and the evidence which we at present possess on the subject tends very strongly to disprove their correctness. Moisture and climate, like all other agents, act either locally or generally; popular belief has attributed their presumed prejudicial effects to local action. They tend, it is said, to produce catarrhs and coughs, and consequently consumption. We need scarcely allude again to the fallacy of this opinion. We are in possession of little information on the mode in which climate operates to the production of phthisis. That the disease prevails to a much greater extent in some climes and localities than in others, is an indisputable fact; but it is no less certain that its prevalence is not confined to countries of variable temperature, for many of such countries suffer in a much less degree than those whose thermometric range varies little throughout the year. Nor does it appear that moist climates and localities are more inimical in this respect; indeed consumption is said to be rare in marshy districts; and Dr. Wells has brought forward a variety of interesting observations to prove that the causes of intermittent fever induce a state of constitution which is a protection from consumption; and he says that in countries where one prevails, the other is always absent, or at least much less prevalent. This certainly coincides with what has been observed on the western coast of Africa, the climate of which is moist in the extreme, and where fevers prevail to a frightful extent; yet diseases of the lungs are rare. It has been also observed that tanners, dyers, wool-scourers, brewers, brickmakers, washerwomen, and many other occupations in which the upper or lower extremities are exposed to wet, and the air is charged with aqueous vapours, present fewer cases of consumption than almost any others. Too much weight however must not be attached to these speculations, for accurate statistical data from fenny countries and localities are still a desideratum; and as respects the immunity enjoyed by persons exercising the trades just enumerated, it will be observed that they are all of them employments combining considerable muscular exertion with free exposure to the air. The wages too of this class of persons are generally such as to place them above want. Is phthisis contagious? This is a question which has been often discussed, and numerous are the testimonies both on the affirmative and negative side; but the weight of the evidence seems to rest with the non-contagionists.

Treatment of Phthisis.—This resolves itself into two kinds: first, the *prophylactic*, or that which has for its object the prevention of phthisis in those who are hereditarily or otherwise predisposed to the disease; and secondly, the *curative*, or that which endeavours to arrest its progress after tubercles have manifested themselves. Much may be done in the first case; but experience proves the limited control that we possess over it in the second. Phthisis, as we have said before—and, as we are anxious to impress this fact upon our readers, we again repeat—is not a mere local disease, or one arising from local causes; but it results from a general depravation or unhealthy condition of the whole system, of which tubercles are only an effect. They may be considered as the last of the embryonic changes previous to the nascence of the disease in a cognisable form.

This being premised, our prophylactic treatment must be directed towards the prevention or the arresting of the incipient changes which take place previous to the development of tubercles. With this view the most obvious rules are, to avoid all those causes which we have pointed out as tending to produce the tuberculous diathesis. Marriages should be made with greater regard to the health of the contracting parties. Children, especially if sickly, should be reared and educated with less anxiety about their mental progress than their bodily strength. Those professions and trades should be avoided which combine much sitting, with a confined posture of body, as those of tailors, shoebinders, shoemakers, milliners, lacemakers, engravers, jewellers, watchmakers, clerks, &c., all of whom are peculiarly subject to phthisis. Agriculturists, butchers, carters, coachmen, sailors, &c., are remarkable for their general health and their freedom from this complaint. All occupations therefore that are carried on in the open air should be chosen in preference to those of an opposite kind. Callisthenic exercises, when indulged in with moderation, are healthful, and should by no means be neglected. In short, everything which tends to invigorate the body diminishes disease; and it is proved by statistical facts, that wherever the mortality from disease generally is low, the mortality from phthisis is also low. The curative treatment of phthisis consists in regulating the health generally, and in combating particular symptoms. For the attainment of the first object, the diet should be nutritious, but not stimulant; and the exercise regular, but gentle, and not too prolonged. Horse exercise is particularly recommended in the incipient stage of phthisis, and travelling may be safely undertaken in certain circumstances. Of all the modes of travelling, sea-voyages are perhaps the most beneficial; and where much improvement has taken place during the voyage, it would be better to repeat it than hazard the doubtful benefit of a residence on land. The influence of climate on consumption, we are inclined to believe, is imperfectly understood. It has been laid down as a general principle, that the change from a variable temperature to one of an opposite description is in the highest degree advantageous, and, *cæteris paribus*, we think this may safely be admitted; but in recommending patients to climates which possess this uniformity of temperature, it has been too often overlooked that there are other counteracting circumstances which more than neutralise this advantage. Examples of the mortality from phthisis in many countries which are remarkable for the equability of their temperature, have been already adduced in a previous part of this article, where it has also been shown that the Madras presidency of India, and the eastern frontier of the Cape of Good Hope settlement, to which may be added New South Wales and South Australia, all of them countries subject to sudden and great changes of temperature, enjoy an extraordinary immunity from phthisis. The practice of sending patients to a foreign country who are in the last stage of consumption, cannot be too strongly reprobated. Much difference of opinion exists on the relative advantages attending a residence on the coast or inland for consumptive patients. From the great benefit of sea-air in all scrophulous disorders, and from a review of the causes of phthisis, we are inclined to think that the sea-coast on the whole is preferable. Where circumstances render removal to an anti-phthisical country impossible, confinement to apartments where the heat is regulated, and the purity of the air as much as possible preserved, during the more rigorous weather of this climate, may be recommended. It must however be recollected that this mode of treatment, being unfavourable to improvement of the general health, should only be enforced when exposure to the air is constantly attended with increase of the symptoms. The invention of the respirator has in a great measure obviated this inconvenience; and the phthisical patient, when warmly clad and furnished with this instrument, may be allowed to take exercise in the open air, not only with impunity, but with positive benefit. Among the medicines which have been employed in the general treatment of phthisis, emetics must be first mentioned. It is remarkable, says Dr. Young, that a very great majority of the cures of consumption related by different authors have either been performed by emetics or by decidedly nauseating remedies. It is evident that the effects of vomiting are general, and not confined to the stomach. The mechanical pressure upon the abdominal and thoracic viscera, the influence upon the arterial and venous circulations, the effects upon the nervous system, and the subsequent diaphoresis, all point out that the action of vomiting is general and complicated; and, associated with the benefits resulting from sea-voyages, swinging, &c., there is every reason to believe that the use of emetics in incipient cases of phthisis is satisfactorily demonstrated.

From the efficacy of bark, sarsaparilla, iron, and iodine, in scrophula and some other diseases attended with constitutional debility, it has been imagined that these medicines must necessarily prove beneficial in phthisis; and there can be no doubt that their tonic properties, when not contra-indicated by the existence of inflammation or much febrile excitement, may safely be put in requisition in the treatment of phthisis. Another class of remedies, of a totally different nature, but not less efficacious when judiciously applied, may be called anti-inflammatory. Such are bleeding, either general or local; mercury, digitalis, counter-irritation. The last is one of the most powerful therapeutic agents that we possess, and, like all other remedies, when used in the commencement of disease presents the greatest chance of success. It is inapplicable when much fever is present, and should never be carried to the extent of producing constitutional disturbance.

These are the general remedies employed in phthisis. The more prominent symptoms of the disease require to be combated by particular medicines which we have yet to name, or by a combination of those just enumerated. One of the most constant and harassing of the symptoms of consumption is cough, which, by interrupting sleep and accelerating the circulation, exerts an injurious influence over the general comfort and health of the patient. It may be tranquillised by the application of sinapisms, tartar emetic ointment, or stimulating plasters to the walls of the chest; or the direct local application of the vapours of chlorine and iodine to the internal surface of the bronchial tubes by means of inhalation may be tried. In addition to these measures, the cough may be calmed by mucilaginous mixtures, decoctions of Iceland moss, small doses of hyoscyamus, Prussic acid, opium, æther, &c. Perspirations in phthisis are very common, and when profuse, tend to weaken the patient. They are checked by exhibiting acids. The sulphuric acid given in bark, or the nitric acid in a decoction of sarsaparilla, are the most eligible combinations for combating this symptom. We have seen that the diarrhœa which takes place in phthisis is the result of inflammation and ulceration of the intestinal canal: a knowledge of this fact will at once regulate our treatment. All stimulating food and medicine must be avoided; the external surface of the body generally, and the abdomen in particular, should be kept warm; gentle counter-irritation may be made to the latter, and small doses of rhubarb and opium, chalk and opium, or lime-water and milk, may be given internally. With respect to the treatment of pneumonia and pleurisy, which are so frequent in the latter stages of phthisis, we cannot be too cautious. It must never be forgotten that they are mere complications; and in any depletory measures which may be thought necessary, the original disease upon which they are engrafted must not be lost sight of. On the whole, local bleeding by leeches or cupping is preferable to venesection, and counter-irritation to both. For a full account of hæmoptysis and its treatment, see Hæmoptysis.

PHULWA, or the *Vegetable Butter of Almora*, is the produce of the chooree, or butter-tree (Bassia butyracea of botanists) of Kumaon, in the eastern district of which it grows. It is peculiarly abundant in the adjoining Goorkhalee province of Dotee, where the butter forms an article of commerce. Hence, in its crude state, it is cheaper than ghee (clarified butter), and is used to adulterate that article. It answers well for lamps, burning with a bright flame, neither the smell nor the smoke being so great as is the case with oil; and Mr. Traill, who was commissioner in Kumaon, used it for this purpose in preference to cocoa-nut oil. This substance has been analyzed by Mr. E. Solly, who describes it as existing in the solid form at ordinary temperatures: at about 120° Fahr. it is perfectly melted, and appears then as a pale yellow oil. A specimen of the phulwa which was brought to this country five years previously was found to consist of sixty parts of solid oil, thirty-four of fluid oil, and six of vegetable impurities. See Bassia for a description of the tree; and *Proc. Com. of Commerce and Agriculture of Royal Asiatic Society*, 1839.

PHYLLA'STREPHUS, Mr. Swainson's name for a genus of *Merulidæ*, placed by him in his subfamily *Brachypodinæ*, or *Short-footed Thrushes*. For the generic character see the article Merulidæ [vol. xv., p. 121]. The name was given, as Mr. Swainson observes, in consequence of one of the species, according to Le Vaillant, loving to shelter and hunt among heaps of dead leaves. Mr. Swainson further remarks that, as yet, but two species are known, and these are from the African continent; the long straight bill of these, he adds, is continued to the genus *Micropus*, Sw. (*Classification of Birds*, vol. ii.)

PHYLLIDIANS, Lamarck's name for a family of *Gastropodous Mollusks*, including the genera *Phyllidia*, *Chitonellus*, *Chiton*, *Patella*, *Patelloidea*, and *Siphonaria*.

M. Deshayes, in the last edition of Lamarck, observes that zoologists are not agreed as to the nature and relations of the genera which Lamarck has collected in this family under the common character of having branchiæ placed circularly round the body between the foot and the mantle. In the first edition of the 'Règne Animal,' he remarks, Cuvier formed at the end of his *Gasteropoda* a small family under the name of *Cyclobranchians*, in which he places the Chitons and Limpets, whilst he arranges the family of *Inferobranchians*, containing the *Phyllidiæ* and *Diphyllidiæ*, at the commencement of the *Gastropods*. Nevertheless it may be said, with reference to the disposition of their branchiæ, that these last two genera are as much *Cyclobranchians* as the Limpets and Chitons; but, adds M. Deshayes, Cuvier doubtless found in the organization of these different mollusks sufficient reasons for separating them. M. de Férussac, in his systematic tables, preserved the two families of Cuvier in the same position, but converted them into orders. That of the *Inferobranchians* was augmented by the genus *Umbrella*, and the order of *Cyclobranchians* was divided into two families, the Limpets and the Chitons. M. de Blainville (*Malacologie*) proposed another distribution of the *Cyclobranchians* of Cuvier. The former zoologist retained the *Inferobranchians*, of which he formed an order towards the end of the *Monœcious Mollusks*; but considering the Chitons as a type intermediate between the *Mollusks* properly so called, and the *Cirrhipeds*, he made in his arrangement a subtype, under the name of *Malentozoaria*, for the assemblage of these two kinds of animals, dividing them into two classes, one of which, the *Polyplaxiphora*, was for the *Chitons*. With the exception of M. de Blainville, the opinions of other naturalists may be referred either to that of Cuvier or that of Lamarck. M. Deshayes says, in conclusion, that after having for a long time directed his special attention to this question, he thinks that the mollusks comprised by Lamarck in his family ought to be separated; for some, as *Chitonellus*, *Chiton*, and *Patella*, are hermaphrodites; others, the *Phyllidians* namely, are monœcious.*

PHYLLO'DIUM is that organ which in the greater part of the New Holland Acacias, or wattle-trees, stands in the place of leaves. When such plants are young, they are clothed with the pinnated leaves, characteristic of the Acacias of extra-Australian countries; but the leaflets soon drop off or cease to appear, and the petiole enlarges from a linear connection between the leaflets to a broad leafy expansion which presents one of its edges to the sky and the other to the earth. That expansion is the phyllodium, which is therefore a peculiar modification of the petiole, whose surface is extended in order to compensate for the diminution of respiratory and digestive power consequent upon the loss of the leaflets by which those functions would be otherwise performed.

PHYLLO'PODA, Latreille's name for a section of crustaceans which have the head confounded with the trunk; the eyes sessile, smooth, and closely approximated; a delicate buckler formed of a single piece, and free posteriorly, serving as a crust or shell; two horny demi-cylindrical mandibles, with a compressed, straight, and very dentilated point, but without palps; first pair of feet in the form of oars, and terminated by articulated bristle-like appendages; the others branchial, and more than sixty (pairs) in number, disposed for swimming.

---

* Quære de hoc.

The genus *Apus* of Scopoli (*Binoculus*, Geoffr., Leach; *Limulus*, Mull., Lam.; *Monoculus*, Linn., Fabr.) will serve as an example of the *Phyllopoda*. [BINOCULUS. N.B. The printer has reversed the cut, and placed the tail uppermost.]

PHYLLOSO'MA. The family of *Double-cuirassed Crustaceans* (*Bicuirassés*), is composed of forms which are very remarkable for their rounded shape and the transparency of their teguments. The *carapace* is large, lamellar, extended like a leaf horizontally above the base of the antennæ and a more or less considerable portion of the thorax. The thorax is equally depressed, so as to resemble a thin blade or plate placed horizontally, and to the existence of these two bucklers, so to speak, they owe the name (*Bicuirassés*) given to them by Latreille. The ophthalmic ring is but little if at all distinct from the interior border of the carapace, and it is from this border also that the antennæ spring. The *eyes* are very large and projecting. The *antennæ* spring below and behind their peduncle, on the same transversal line, and are directed forwards; those of the first pair are bifid at the end, and the conformation of those of the second pair varies. The *mouth* is situated very far from the base of the antennæ, and is found towards the anterior third or the middle of the lower surface of the carapace; it has the form of a rounded tubercle, and is composed essentially of a large *upper lip*, a pair of hooked *mandibles* which want a palpiform stem, a membranous and bilobated *lower lip*, and a pair of jaws; sometimes there are to be found a second pair of jaws and even jaw-feet applied against the mouth, but in general those organs are rudimentary and thrown rather far backwards. The great flattened blade or plate, which constitutes the thorax, commences immediately behind the mouth, and presents no annular divisions; in general it reaches a good deal beyond the carapace, and gives insertion to the feet by its lateral borders, so that those organs are very distant from the median line. The number of feet consists of from seven to eight pairs, but those of the first pair, and, sometimes, those of the last, are very short, whilst the others are very long; all are very slender, and lead, towards a third of their length, to a large flabelliform appendage, which is analogous to the external branch of the thoracic feet of the *Mysians*, but which takes its origin much farther from the body. The *abdomen* is slender, and sometimes rudimentary; in general, nevertheless, it is terminated by a fin composed of five blades disposed in a fan-shape, as in the family of the *Caridoïds*. The false feet are always more or less rudimentary.

These crustaceans do not present any organs which can be considered as *branchiæ;* some naturalists give this name to the ciliated appendage which represents the palp of the thoracic feet, but without resting this conclusion on any fact; and M. Milne Edwards is disposed to believe that respiration is carried on by means of the general surface of the body. (*Histoire Naturelle des Crustacés.*)

M. Milne Edwards, whose definition of this family we have above given, makes it consist of two genera only, *Phyllosoma* and *Amphion*. He observes that the *Phyllosomata* are easily recognised by their foliaceous carapace, which leaves part of the thorax exposed. In *Amphion*, the carapace hides the thorax entirely.

Phyllosoma. (Leach.)

Generic Character.—This, one of the most remarkable genera known, is composed of animals whose body is so much flattened, that there is scarcely an interval between the teguments of the upper and lower surfaces, so that it is difficult to comprehend how the viscera are there lodged. This lamellar body is divided into three distinct parts; the head, the thorax, and the abdomen.

The *head* has the form of a delicate disk or of an ordinary oval leaf, and only adheres to the thorax by its central portion, so that the borders all round are free. This species of buckler is wide and horizontal; at its anterior extremity it gives insertion to the eyes and to the antennæ. The eyes spring near the median line, and are globular; they are carried on slender, cylindrical, and very long peduncles. The *internal antennæ* spring equally from the border of the carapace, immediately outside the ocular peduncles; they are very small, and present a peduncle composed of three cylindrical joints and two terminal filaments. The *second pair of antennæ* have their origin on the outside of the preceding, and vary much in their form: sometimes they are very long, slender, cylindrical, and composed of many distinct joints; at other times they are short, lamellar, without apparent divisions, and seem to be only prolongations of the carapace. The *mouth* is situated towards the middle or even towards the posterior third of the carapace, and is only composed of a labrum, a pair of mandibles, a lower lip, and a pair of jaws. The *mandibles* are large, rounded externally, and armed internally with two trenchant edges and a small tooth. The *lower lip* is large, very apparent, and deeply bilobated; the *jaws* are small, membranous, and each terminated by two lobes or blades directed inwards, and armed with some spines towards their summit. The appendages which represent the jaws of the second pair, and the first jaw-feet, are rudimentary, and do not enter into the composition of the buccal apparatus; they are thrown more or less far backwards, and fixed to the thoracic buckler like the feet. The jaws of the second pair are represented by a lamina or blade, which is sometimes rather large and oval, sometimes entirely rudimentary. A pair of tubercles, situated a little behind these last appendages, are the only vestiges of limbs, which ordinarily constitute the jaw-feet of the first pair.

The *thorax* is lamellar like the carapace, and constitutes a second buckler, the anterior portion of which only is covered by the first of these foliaceous disks. It is in general wider than it is long, and striated transversely, but it presents no trace of a division into rings. The *feet* are inserted all round the disk: the first pair are very small, and hidden under the carapace; they are slender, cylindrical, and unguiculated at the end; sometimes they are not furnished with appendages, sometimes they give origin from the extremity of their last joint to a flabelliform palp. The five or even six succeeding pairs are very long, and sufficiently similar to each other; like the first pair, they are cylindrical and very slender, and they each take their origin on a cylindrical prolongation of the border of the great thoracic plate. Their first joint is very long, and carries at its extremity a flagelliform palp, composed of a cylindrical joint, and of a multiarticulate stem furnished with numerous hairs. The succeeding joints of the principal branch of the feet present nothing remarkable, but are very easily detached, so that in general they are not found, and the feet appear to be terminated by a ciliated appendage. The first pair of feet end in a slender and elongated joint, while the four or five succeeding pairs are terminated by a rather strong nail; the last pair are sometimes similar to the preceding, sometimes rudimentary and without the flabelliform palp. At the base of the anterior feet, or even of all the organs, are found small vesicular appendages, which seem to be the vestiges of the flagrum (or external branch) of those members. The disposition of the abdomen varies: sometimes it is elongated, divided into very distinct rings, and perfectly distinct from the thorax which covers its base; sometimes it is confounded with the buckler, and only seems to be a prolongation of it. In this last case it varies still, for sometimes it is very wide at the base, and occupies the whole space comprised between the posterior feet; whilst in other cases it is rudimentary and lodged at the bottom of the re-entering angle formed by the border of the thoracic plate. Six or seven rings can nearly always be distinguished on it, the last of which forms, with the appendages of the succeeding segment, a more or less developed caudal fin. The number of the false feet fixed under the abdomen varies, and they are in general rudimentary. (M. Edwards.)

Nervous System and General Organization.—The nervous system of the *Phyllosomata* presents a remarkable mode of conformation; the mass formed by the cephalic ganglion is situated near the base of the antennæ, and communicates with the thoracic ganglions by means of two very long chords. The thoracic ganglions are not united on the median line, but communicate with each other by transversal commissures: there are nine pairs. The abdominal ganglions are very small, and amount to six pairs. The intestine seems to be straight, and in the interior of the cephalic buckler are to be perceived a great number of vessels which diverge laterally. M. Milne Edwards observes that M. Guerin thinks that these vessels may belong to the circulatory apparatus; but this opinion does not appear to M. Milne Edwards to be admissible, and he considers that this apparatus is the analogue of the liver. He acknowledges that he knows nothing of the organs of reproduction in these crustaceans, and adds, that their habits have not been studied.

Geographical Distribution of the Genus.—The seas of warm countries. M. Milne Edwards remarks, that were it not for the beautiful blue of their eyes, they would not be perceived as they float on the surface of the water, so transparent are their bodies. The seas of Africa and India, New Holland and New Guinea, furnish the greatest number of species. *Phyllosoma Mediterranea* appears to have been the only European species known, till Mr. F. C. Lukis noticed another of these remarkable crustaceans in the 8th volume of Loudon's *Magazine of Nat. Hist.* The figure in Loudon is very correct, but Mr. Lukis has called our attention to a slight mistake in the position of the letters of indication. Letter *a* in the note at the foot is made to point to the ventral aspect, whereas it should indicate the *dorsal*, which in the description is assigned to letter *b*: but this last letter, in the cut, indicates the ventral aspect. Since the publication in Loudon, Mr. Lukis has confirmed the presence of the species on the shores of the Atlantic by another specimen taken at Guernsey, and he proposes for it the name of *Phyllosoma Sarniense.*

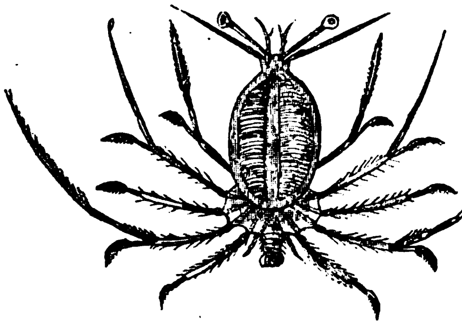
The species are very numerous, and exhibit differences in their organization so great, that M. Milne Edwards thinks it will be probably necessary hereafter to establish many generic divisions for these forms; but, as he cautiously and philosophically observes, until the modifications of structure dependent upon sex and age are known, the value of those differences cannot be well appreciated: he therefore thinks it preferable to take those differences only for the base of simple subgenera, and he divides the genus into the three following natural groups:—

1.
Ordinary Phyllosomata.

Abdomen very distinct from the thorax, large, divided into rings, and terminated by a well-developed caudal fin.

The *Phyllosomata* of this division, in the opinion of M. Milne Edwards, approach, more than the others, the *Caridoïds* and the *Amphions*, for their abdomen, though flattened, much resembles that of the Shrimps (*Salicoques*). The cephalic buckler is oval and very much elongated. The external antennæ are setaceous, very long, in general divided into many joints and without a dilatation of an auricular form at their base. The two first pairs of feet, which correspond to the jaw-feet of the second and third pair in the Decapods, carry a flabelliform palp. The thoracic plate is nearly circular, and its lower part is narrow and but little or not at all notched. The posterior feet are rudimentary. The abdomen is rather large, not much narrowed backwards, composed of very distinct rings, and is terminated by a caudal fin, the four lateral blades of which are nearly as long as the middle blade.

Example, *Phyllosoma commune.*

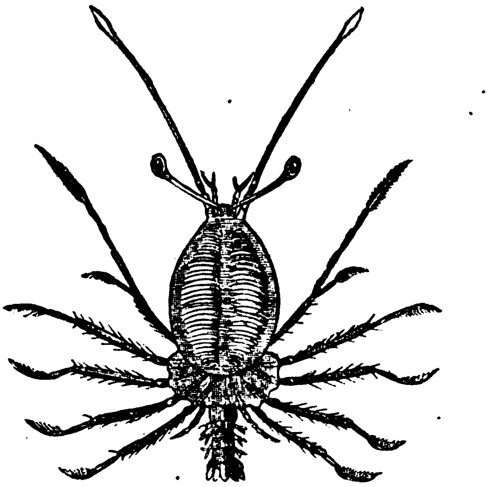


Phyllosoma commune.

Description.—Cephalic plate less than the thoracic plate, covering the base of the second pair of feet (or external jaw-feet), elongated, and narrowed forwards. External antennæ styliform, much longer than the ocular peduncles, and composed of five joints (without reckoning the peduncle which supports them, and which is only a prolongation of the border of the carapace), of which the third is very small, the fourth shorter than the ocular peduncle, and the last nearly half the length of the preceding, and not convex. Mouth situated towards the posterior third of the carapace, and very near the jaws of the second pair, which have the form of large oval blades. Jaw-feet represented by a small ciliated appendage carried on a large tubercle. Anterior feet (or jaw-feet of the second pair) reaching beyond the mouth, and having at their base, as well as at the base of the succeeding feet, a small vesicle. Abdomen scarce more than one-half as long as the thorax. Length about an inch.

Locality.—The seas of Africa and India.

Phyllosoma clavicorne, from the seas of Africa and Asia, is another example of this section.



Phyllosoma clavicorne.

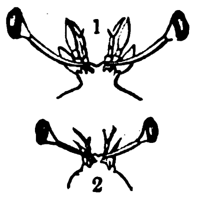
The other two sections consist of those *Phyllosomata* whose abdomen is intimately united with the thorax, without well distinguished divisions, and terminated by a very small caudal fin.

2.
Short-tailed Phyllosomata.

Abdomen in general rudimentary and lodged in the middle of a great notch on the posterior border of the thorax.

In this group the abdomen presents nearly the same form as in the *ordinary Phyllosomata*, but is in general nearly rudimentary, and is always lodged in the middle of a re-entering angle formed by the posterior border of the thoracic plate; the false feet are ordinarily reduced to the state of vestiges, and the caudal fin is in general very incomplete. The conformation of the external antennæ is equally characteristic; these appendages are shorter than the internal antennæ, and have the form of a blade without transversal divisions, which presents externally an articuliform prolongation or point, and which itself seems to be a simple prolongation of the border. The anterior jaw-feet are nearly always reduced to a state still more rudimentary than they are in the *ordinary Phyllosomata*, and the feet of the two first pair want the flagelliform palp.

Phyllosoma laticorne and *Phyllosoma brevicorne*, the eyes and antennæ of which are represented below, are examples of this section.



1, eyes and antennæ of Phyllosoma laticorne; 2, eyes and antennæ of Phyllosoma brevicorne. The first of these species is found in the Indian seas, and the second in the seas of Africa and Asia.

3.
Broad-tailed Phyllosomata.

Abdomen large, triangular, and occupying the whole length of the posterior border of the carapace.

The *Phyllosomata* of this division are remarkable for the great size of their carapace, and especially for the conformation of their abdomen, which is triangular, occupies the whole space comprised between the base of the posterior feet, and continues with the thorax without interruption, so as to form with it a single plate. The external antennæ are short, lamellar, and furnished externally with an articuliform prolongation, as in the preceding section. The disposition of the external jaw-feet and of the anterior jaw-feet is the same as in the *ordinary Phyllosomata*, whilst the feet of the two first pairs want the flabelliform palp, as in the *Short-tailed Phyllosomata*. The posterior feet are rudimentary. The abdomen is terminated by a fin consisting of five rather large blades; but the false feet of the preceding rings are rudimentary.

Phyllosoma spinosum (Azores) and *Phyllosoma Mediterraneum* (Mediterranean), &c., are examples of this section.

Amphion. (M. Edwards.)

M. Milne Edwards states that the *crustacea* which he has designated under the name of *Amphion* approach nearer to the *Phyllosomata* than any of the other *Stomapods*, but in some respects they resemble also the genera *Alima* and *Mysis*, and he is of opinion that they establish the natural passage between these animals. Their cephalic buckler or carapace is foliaceous, like that of the *Phyllosomata*, whilst the form of the abdomen and the caudal fin is that of *Mysis*.

The *cephalic buckler* is very much developed and entirely lamellar; it extends to the origin of the abdomen and hides the base of the feet; its longitudinal diameter is more than twice its transversal diameter, and on each side it is curved a little downwards; its anterior border is nearly straight, and leaves exposed the ring which carries the eyes. There is no trace of a rostrum, but on each side the angle formed by the union of this border with the lateral border is prolonged forwards after the fashion of a spine. The posterior border of the carapace, which is short and nearly straight, is continued with the lateral borders without forming well marked angles. The eyes are very large; their terminal portion has the same form as that of the *Phyllosomata*, but the narrow stem which supports them, instead of being very long, as in those crustaceans, is extremely short. The four *antennæ* are inserted on the same line, immediately below and behind the ocular peduncles. The first pair have the same general form as in the *Phyllosomata;* their basilary portion is composed of three slender and cylindrical joints, the first and last of which are the longest, and they each terminate by two small filiform stems, the internal one very short, and the external one nearly of the length of the basilary portion. The external antennæ are much more developed, and do not at all resemble those of the *Phyllosomata;* they approximate much in their general form to those of the *Alimæ*, but, instead of being directed downwards and outwards, they are straight and directed forwards. Their first joint, which is not very distinct, gives insertion internally to a cylindrical stem, and externally to a great lamellar appendage; this lamina, which is nearly oval, goes much beyond the edge of the basilary portion of the internal antennæ; its internal and anterior borders are ciliated, and its external border is terminated by a spine. The stem is composed of two small very short basilary joints, and of a long terminal joint slightly convex towards the end; its length is almost double that of the lamina which covers its base.

The disposition of the mouth is nearly the same as in the *Phyllosomata;* it is very distant from the antennæ, and forms towards the anterior third of the cephalic buckler a small rounded tubercle, from the posterior part of which the thorax springs. The parts which enter into its composition are a labrum, two mandibles, a tounglet (languette), two pairs of jaws, and two pairs of jaw-feet. The *labrum* is transversal and but little developed. The *mandibles* carry no palp, and are in great part hidden by the tounglet, which is bilobated. The *jaws* (first pair) are nearly rudimentary, and appeared to M. Milne Edwards to consist only of a small horny blade, the border of which is ciliated. The second pair are composed of two joints, the first of which presents internally a prolongation furnished with spines. The *jaw-feet* of the first and second pair, which in the *Phyllosomata* exist only in the state of vestiges and do not enter into the composition of the buccal apparatus, are, on the contrary, here very much developed and applied upon the jaws. Those of the first pair present within many tounglets furnished with hairs at their extremities, and on the external side of their base with a large foliaceous and oval appendage. The jaw-feet of the second pair are much more developed than the preceding; their basilary joint is lamellar, and carries on its anterior part, 1st, a cylindrical stem composed of three joints; 2nd, a flabelliform appendage, or a species of palp, which advances to the external side of the stem and reaches beyond it. The *thorax* is flattened, as in the *Phyllosomata*, but narrower, and completely hidden under the carapace: it gives attachment to six pairs of feet having the same disposition as in those crustaceans; the whole are slender and cylindrical, and at the extremity of their second joint springs a palpiform appendage, composed of a cylindrical joint terminated by a multiarticulated and ciliated bristle. The first pair of feet, those which correspond to the external jaw-feet of the *Decapods*, are inserted very far from the mouth, and are much shorter than the others; their second joint is terminated forwards by a sharp spine. The three succeeding pairs of feet become longer and longer, and have at the edge of their third joint one, two, or three spines, similar to that which exists at the extremity of the second joint. The fifth pair of feet, which are rather shorter than the fourth pair, present the same disposition; the last pair are much shorter than the preceding, and present no very distinct spines. The *abdomen* is nearly as long as the cephalo-thoracic portion of the body, and is composed of seven segments. Its form is the same as that of the abdomen of the *Salicoques*, and terminates by a fan-shaped fin, the median piece of which (formed by the seventh ring) is lanceolate, and the lateral pieces of which are oval. The appendages fixed under the first five rings of the abdomen are rudimentary.

The only species known, *Amphion Reynaudii*, was taken at sea in the Indian Ocean by M. Reynaud, naval surgeon. Its length is about an inch, and its teguments, with the exception of those of the abdomen, are diaphonous. (*Histoire Naturelle des Crustacés.*)

PHYSA. [LIMNEANS, vol. xiii., p. 409.]

PHY'SALUS. [PHYSOGRADA.]

PHYSE'TER. [WHALES.]

PHYSIC NUT, the colonial name of the nut of the Jatropha Curcas, an East Indian plant, whose seeds are employed by the natives as a purgative. It is common on the coast of Coromandel, where it forms a small tree or bush, and is called Baghbarinda. The seeds are violently emetic and drastic, in large doses energetic poisons; one seed is sufficient for a dose. The oil of the plant boiled with oxide of iron forms a varnish, used by the Chinese for covering boxes. (Lindley's *Flora Medica*, No. 375, p. 184.)

PHYSICIAN (ὁ φυσικός), a word derived from φύσις, *nature*, which meant originally what we should now call a *natural philosopher*, or one of those persons who have for their object the investigation of nature and its laws, in opposition to οἱ ἠθικοί, or those who examine particularly into the moral nature of men. [PHILOSOPHY.] In English however the word *physician* is used only to designate the professors of the healing art, called in Greek ἰατροί, and in Latin *medici;* while in most (if not all) other European languages the derivatives of the Greek word are still employed in their original meaning, and the idea of *healing* is expressed either by some native word or by one derived from the Latin.[*] The origin and progress of physic, together with an account of the different medical sects, has been given already under MEDICINE; in the present article it is proposed to mention some of the most curious and interesting facts respecting the rank, education, &c. of the physicians of antiquity, and afterwards to state the legal qualifications for practising this branch of the medical profession in our own country.

In Greece and Asia Minor the profession of medicine seems to have been held in high esteem, for, not to mention the apotheosis of Æsculapius, who was considered as the father of it, there was a law at Athens that no female or *slave* should practise it (Hyginus, *Fab.*, cap. 274); Ælian mentions one of the laws of Zaleucus among the Epizephyrian Locrians, by which it was ordered that if any one during his illness should drink wine contrary to the orders of his physician, even if he should recover, he should be put to death for his disobedience (*Var. Hist.*, lib. ii., cap. 37); and there are extant several medals struck by the people of Smyrna in honour of different persons belonging to the medical profession. (Mead's *Dissertatio de Nummis quibusdam à Smyrnæis in Medicorum Honorem percussis*, 4to., Lond.,

---

[*] Somewhat analogous to this is the use of the Arabic word *hakim* (from *hakama*, 'novit,' 'sapiens fuit'), which properly means *a wise* or *learned man* in general, but is very frequently used in a restricted sense to signify *a physician*.

1724.) If the Decree of the Athenians (published among the letters of Hippocrates) be genuine, and if Soranus (*in Vitâ Hippocr.*) can be depended on, the same honours were conferred upon that physician as had before been given to Hercules; he was voted a golden crown, publicly initiated into the Eleusinian mysteries, and maintained in the Prytaneum at the state's expense. (See also Pliny, *Hist. Nat.*, lib. vii., cap. 37.) Some idea of the income of a physician in those times may be formed from the fact mentioned by Herodotus (lib. iii., cap. 131), that the Æginetans (about the year B.C. 532, Ol. 62, 1) paid Democedes from the public treasury one talent per annum for his services, *i.e.* (if we reckon, with Hussey, *Antient Weights and Money, &c.*, the Æginetan drachma to be worth 1*s.* 1¾*d.*) not quite three hundred and forty-four pounds; he afterwards received from the Athenians one hundred minæ, *i.e.* (reckoning, with Hussey, the Attic drachma to be worth 9¾*d.*) rather more than four hundred and six pounds; and he was finally attracted to Samos by being offered by Polycrates a salary of two talents, *i.e.* (if the Attic standard be meant) four hundred and eighty-seven pounds, ten shillings. It should however be added that Valckenaer doubts the accuracy of this statement of Herodotus with respect to the Æginetans and Athenians (and apparently with reason), on the ground that the latter people, at the time of their greatest wealth, only allowed their ambassadors two drachmæ (or 1*s.* 7½*d.*) per day, *i.e.* somewhat less than thirty pounds per annum. (Aristoph., *Acharn.*, v. 66.) It seems to have been not uncommon in those times (as afterwards in the later Roman empire, see ARCHIATER), for states to maintain physicians, who were paid at the public cost (Xenophon, *Memor. Socr.*, lib. iv., cap. 2, § 5; Plato, *Gorg.*, § 23; Strabo, lib. iv., p. 125; Diod. Sic., lib. xii., cap. 13); and these again had attendants, for the most part slaves, who exercised their calling among people of low condition. (Plato, *De Leg.*, lib. iv., p. 720, ed. Steph.; Boeckh's *Public Econ. of Athens*, vol. i., p. 160.)

In the earlier times of the Roman republic physicians were unknown (Pliny, *Hist. Nat.*, lib. xxix., cap. 5, ed. Tauchn.); and for some time afterwards the exercise of the profession was in a great measure confined to persons of servile rank; for the richer families having slaves who were skilled in all sorts of trades, &c., generally possessed one or more that understood medicine and surgery. (Middleton's Essay *De Medicorum apud Romanos degentium Conditione*, Cantab., 1726, 4to., and the various answers to it that appeared on its publication.) To this practice however there were many exceptions: *e.g.* the physician who was taken prisoner with Julius Cæsar by the pirates at the island of Pharmacusa (Sueton., cap. 4), and who is called his friend by Plutarch (see Casaubon's Note on Sueton.); Archagathus, who, being the first foreign surgeon that settled at Rome, had a shop bought for him at the public expense, and was presented with the Jus Quiritium, A.U.C. 535, B.C. 219 (Cassius Hemina ap. Pliny, *Hist. Nat.*, lib. xxix., cap. 6); Artorius, who is known to have been a physician (Cæl. Aurel., *De Morb. Acut.*, lib. iii., cap. 14, p. 224), and who is called the friend of Augustus (Plutarch, *Vita Bruti*, cap. 41, ed. Tauchn., where however it should be noticed that some editions read 'Αντώνιος instead of 'Αρτώριος); Asclapo, whom Cicero calls his friend (*Epist. ad Divers.*, lib. xiii., ep. 20); Asclepiades, the friend of Crassus the orator (Cic. *de Orat.*, lib. i., cap. 14); Eudemus, who is called by Tacitus (*Annal.*, lib. iv., cap. 3) the friend and physician of Livia; and others. With respect to the income made by eminent physicians at the beginning of the Roman empire, we learn from Pliny (*Hist. Nat.*, lib. xxix., cap. 5) that Albutius, Arruntius, Calpetanus, Cassius, and Rubrius gained two hundred and fifty thousand sesterces per annum, *i.e.* (reckoning with Hussey the mille nummi (*sestertium*) to be worth, before the reign of Augustus, 8*l.* 17*s.* 1*d.*) about two thousand two hundred and thirteen pounds, ten shillings; that Quintus Stertinius made it a favour that he was content to receive from the emperor five hundred thousand sesterces per annum (or rather more than four thousand four hundred and twenty-seven pounds), as he might have made six hundred thousand sesterces (or five thousand three hundred and twelve pounds, ten shillings) by his private practice; and that he and his brother, who received the same annual income from the emperor Claudius, left between them at their death, notwithstanding large sums that they had spent in beautifying the city of Naples, the sum of thirty millions of sesterces (or two hundred and sixty-five thousand six hundred and twenty-five pounds). Of the previous medical education necessary to qualify a physician for the legal practice of his profession in the early times, we know nothing; afterwards however this was under the superintendence of the Archiatri. [ARCHIATER.]

Among the Arabians the medical profession appears to have been held in high esteem. Many of their chief physicians were Jews or Christians, and some apostatised to Mohammedanism: in some families the profession would seem to have been in a manner hereditary, as in that of Avenzoar (*Ibn Zohir*), five of whom successively belonged to it. (Reiske's *Abulfedæ Annal. Moslem.*, tom. iv., p. 669.) The qualifications necessary for practising medicine seem to have been rather slight, till the Caliph Moctader, A.H. 319 (A.D. 931), in consequence of an ignorant practitioner's having killed one of his patients, passed a law that no one should be allowed to practise until he had been licensed to do so by the chief physician. (Casiri, *Biblioth. Arabico-Hisp. Escur.*, tom. i., p. 438.) Some idea of the consideration in which the Arabic and Moorish physicians were held may be gained from the fact that Sancho the Fat, king of Leon, was obliged to go in person to Cordova, A.D. 956 (A.H. 345), to be cured of an illness. (Mariana, l. viii., c. 7, tom. i., p. 318; Conde, *Domin. des Arabes, &c.*, t. i., p. 448.)

The first medical school that was established in Europe was that at Salerno (Salernitana Schola) towards the end of the seventh century; the second was probably that at Montpelier, founded about a hundred years afterwards. their course of medical education is unknown, but they doubtless exercised a most beneficial influence on the acquirements, and therefore on the personal rank and consideration of the physicians of the age. For a long time however the profession of medicine was almost entirely confined to the clergy, who indeed were the only persons in those days that possessed any share of learning. Surgery was however given up to the laity, as the clergy were prohibited from undertaking any bloody operation.

Hence arose the distinction of the three regular orders of the medical profession, viz. physicians, surgeons, and apothecaries; and it is to the first of these exclusively that the remainder of this article will be dedicated. The degree of bachelor of physic seems to have been known at Oxford soon after the Conquest; and in the fourteenth century we find that the degree of doctor of physic was by no means uncommon. (Wood's *Hist. of Oxford*, vol. ii., p. 765, ed. Gutch; Chaucer's *Doctor of Physic's Tale.*) The English colleges could not of their own authority prevent any from undertaking to practise, though they had not obtained a degree in physic. On this account therefore, in the ninth year of the reign of Henry V., 1422, our universities proposed that an act of parliament should be passed ordering that 'No one shall use the mystery of physic unless he hath studied it in some university, and is at least a bachelor in that science. The sheriff shall inquire if any one practises in his county contrary to this regulation; and if any one so practise, he shall forfeit forty pounds and be imprisoned: and any woman who shall practise physic shall incur the same penalty.' (Quoted in Willcock, *On the Laws of the Medical Profession*, part ii., p. iii.)

This measure had not however the desired effect; indeed there appears to be some doubt whether it ever obtained the force of an act of parliament, on account of its being referred to the privy council for confirmation. In the third year of the reign of Henry VIII., 1511, was passed an act, which is generally received as the first operative law on the subject, and which takes no notice of the supposed statute of Henry V. By this, which is especially aimed against the sorcerers, witches, and smiths, 'who can no letters on the book,' it is enacted 'that no person within the city of London, nor within seven miles of the same, take upon him to exercise or occupy as a physician, except he be first examined, approved, and admitted by the bishop of London, or by the dean of St. Paul's, for the time being, calling to him or them four doctors of physic; upon the pain of forfeiture, for every month that they do occupy as physicians not admitted nor examined after the tenour of this act, of five pounds,' &c., &c. After making the same enactment for the different counties, the act goes on to say, 'Provided always, that this act nor anything therein contained be prejudicial to the universities of Oxford and Cambridge, or either of them, or to any privileges granted to them.' (Willcock, pp. 6, 7; Goodall's *Hist. of the Col. of Physicians*, p. 1-3.)

In the fourteenth year of the same reign, 1522, another act was passed, by which the examination of physicians was taken from the persons appointed for that purpose by the former statute, and reposed in the college instituted by a charter of that king. [PHYSICIANS, COLLEGE OF.] Under this the university graduates who might desire to practise in London were included, as well as the other physicians; and since that time the legislature has seldom interfered on the subject.

With respect to the present state of the profession, the first class of medical practitioners in rank and legal pre-eminence is that of the physicians. They are (by statute 32 Henry VIII.) allowed to practise physic in all its branches, among which surgery is enumerated. The law therefore permits them both to prescribe and compound their medicines, and to perform operations in surgery as well as to superintend them. These privileges are also reserved to them by the statutes and charters relating to the surgeons and the apothecaries. [SURGEON.] Yet custom has more decidedly distinguished the classes of the profession, and assigned to each its peculiar avocations. The practice of the physician is universally understood, as well by their college as the public, to be properly confined to the prescribing of medicines, which are to be compounded by the apothecaries; and in so far superintending the proceedings of the surgeon as to aid his operations by prescribing what is necessary to the general health of the patient, and for the purpose of counteracting any internal disease. It would be impossible to enumerate here the legal qualifications required by all the different European universities; it will therefore be sufficient to mention those recognised in the British dominions.

In the university of Oxford, for the degree of Bachelor of Medicine, it is necessary that the candidate should have completed twenty-eight terms from the day of matriculation; that he should have gone through the two examinations required for the degree of bachelor of arts; that he should have spent at least three years in the study of his profession; and that he should be examined by the Regius Professor of medicine and two other examiners of the degree of M.D. in the theory and practice of medicine, anatomy, physiology, and pathology; in materia medica, as well as chemistry and botany, so far as they illustrate the science of medicine; and in two at least of the following antient medical writers, viz. Hippocrates, Celsus, Aretæus, and Galen. After taking the degree of Bachelor of Medicine, the following licence to practise is delivered to the candidate, under the common seal of the university:—'Cancellarius, Magistri, et Scholares Universitatis Oxoniensis dilecto nobis in Christo, ——— Baccalaureo in Medicinâ, è Collegio ——— intra Universitatem prædictam, salutem in Domino sempiternam. Cum omnia nostra studia, consilia, et actiones ad Dei gloriam et fratrum salutem referri debeant; cumque Medicina ad hæc, inter reliquas facultates, plurimum conferat; hinc est, quòd nos 'Cancellarius, Magistri, et Scholares antedicti (pro eâ opinione, quam de scientiâ tuâ, vitæque ac morum integritate, habemus) liberam tibi, tenore præsentium, concedimus potestatem et facultatem practicandi in Medicinâ, et ea omnia faciendi, quæ ad eam spectant facultatem, ubivis per universum Angliæ regnum, in perpetuum duraturam. Nos etiam Cancellarius, Magistri, et Scholares antedicti, testamur præfatum juramentum de primatu Regiæ Majestatis suscepisse, tam omnibus Articulis Fidei et Religionis in Ecclesiâ Anglicanâ receptis et approbatis, quàm tribus illis Articulis comprehensis in Canone tricesimo sexto Libri Constitutionum et Canonum Ecclesiasticorum, editorum in Synodo Londini cœptâ 1603, et regni Domini nostri Jacobi, &c. primo.

'In quorum omnium majorem fidem et plenius testimonium, sigillum Universitatis Oxoniensis commune, quo hâc in parte utimur, præsentibus apponi fecimus. Datum in Domo nostræ Congregationis, die — mensis — anno Domini millesimo octingentesimo ——.'

For the degree of Doctor of Medicine, the candidate is required to have completed forty terms from the day of matriculation; and to recite publicly in the schools a dissertation upon some subject, to be approved by the Regius Professor, to whom a copy of it is afterwards to be presented.

At Cambridge a student, before he can proceed to the degree of Bachelor of Medicine, must have entered on his sixth year, have resided nine terms, and have passed the previous examination: the necessary certificates, &c. are much the same as those required at Oxford. A Doctor of Medicine must be of five years' standing from the degree of M.B.

Since the university of London has been chartered, in 1837, the degrees of Bachelor and Doctor of Medicine, among others, have been conferred there. Some temporary regulations have been drawn up, which are to continue in force until the year 1842; after that time the following are to be the necessary qualifications for medical degrees:—

For the degree of Bachelor of Medicine.—Candidates to have been engaged for four years in professional study at one or more of the recognised institutions, one year at least to be spent at a recognised institution or school in the United Kingdom. They have also to pass two examinations, at the first of which they must produce certificates of having completed the nineteenth year; of having taken a degree in arts in this university, or in a recognised university, or of having passed the matriculation examination; of having been student for two years at one or more recognised medical institutions, subsequently to having taken a degree in arts: of having attended a course of lectures on descriptive and surgical anatomy, general anatomy and physiology, comparative anatomy, pathological anatomy, chemistry, botany, materia medica and pharmacy, general pathology, general therapeutics, forensic medicine, hygiene, midwifery, surgery, medicine; of having dissected during nine months; of having attended a course of practical chemistry; and of having attended practical pharmacy. Candidates to be examined in anatomy, physiology, chemistry, structural and physiological botany, materia medica, and pharmacy.

To the second examination no candidate can be admitted until two years after passing the first. He must produce certificates of having passed his first examination; of having subsequently attended a course of lectures on each of two out of the four subjects mentioned above; of having subsequently to his first examination dissected for six months; of having conducted at least six labours; of having attended the surgical practice of a recognised hospital or hospitals during twelve months, and lectures on clinical surgery; of having attended the medical practice of a recognised hospital or hospitals during other twelve months, and lectures on clinical medicine; of having subsequently attended to practical medicine in a recognised hospital, infirmary, or dispensary, during six months. The candidate must also produce a certificate of moral character from a teacher in the last school at which he has studied. Candidates to be examined in physiology (including comparative anatomy), general pathology, general therapeutics, hygiene, surgery, medicine, midwifery, and forensic medicine.

For the degree of M.D.—Candidates to produce certificates: 1, of having taken the degree of Bachelor of Medicine in this university, or a degree in medicine or surgery at a university recognised by this university; 2, of having subsequently attended (A) to clinical or practical medicine during two years in a recognised hospital or medical institution; (B) or to clinical or practical medicine during one year in a recognised hospital or medical institution, and of having been engaged during three years in the practice of his profession; (C) or if he have taken the degree of B.M. in this university, of having been engaged during five years in the practice of his profession; 3, of moral character, signed by two persons of respectability.

Candidates who have not taken a degree in arts, or passed the matriculation examination in this university, will be required to translate a portion of Celsus *De Re Medicâ*.

Regulations relating to Practitioners in Medicine or Surgery desirous of obtaining degrees in Medicine.

Degree of Bachelor of Medicine.—Candidates shall be admitted to the two examinations for the degree of Bachelor of Medicine on producing certificates:—1, of having been admitted, prior to the year 1840, members of one of the legally constituted bodies in the United Kingdom for licensing practitioners in medicine or surgery; 2, of having received a part of their education at a recognised institution or school, as required by the charter of the university; 3, of moral character, signed by two persons of respectability.

Degree of Doctor of Medicine.—Candidates who have been engaged during five years in the practice of their profession, shall be admitted to the examination for this degree on producing certificates:—1, of having been engaged during five years in the practice of their profession; 2, of having taken the degree of Bachelor of Medicine in this university.

In Scotland the degree of doctor of medicine is conferred by the universities of Edinburgh, Glasgow, Aberdeen, and St. Andrews, from which last named university a diploma can still be obtained without residence; the regulations at the others contain nothing particularly worthy of notice.

In Ireland, the King and Queen's College of Physicians exercise much the same jurisdiction as the English college. The degrees of Bachelor and Doctor of Medicine conferred by Trinity College, Dublin, rank with the same degrees respectively from Oxford and Cambridge, and are never given without previous study in arts, which occupies four years. For the degree of M.D. five years must have elapsed since the degree of M.B. was conferred; the candidate is then to undergo a second examination, and write and publish a Latin thesis on some medical subject.

By the English law the physician is exempted from serving on juries, from serving various offices, and from bearing arms. He is (according to Willcock, p. 105) responsible for want of skill or attention, and is liable to make compensation in pecuniary damages (as far as such can be deemed a compensation) to any of his patients who may have suffered injury by any gross want of professional knowledge on his part.

Some idea of the amount of fees paid to physicians in the middle ages may be gained by what we are told of Petrus de Abano, one of the most eminent physicians of the thirteenth century. For visiting a patient out of his own city he charged one hundred and fifty francs (or about six pounds) per day; and that when sent for by Pope Honorius IV., he demanded four hundred ducats per day, or about seventy pounds. (Bayle's *Dict.*, art. 'Apone.') It should however be noticed that these charges were considered very enormous.

In England physicians were frequently rewarded by the grant of church livings, prebendaries, and deanaries; and the names of some are preserved who were made bishops. At present it is determined by law that the fee of a physician is honorary, and that it cannot be recovered by an action at law; and that every person professing to act as a physician is precluded from assuming a different character, as that of a surgeon or apothecary, for the purpose of recovering his fees, although he may in fact be a surgeon or apothecary, or a person who had no right to practise as a physician. It has likewise been determined that a custom in the defendant's neighbourhood to pay physicians at a certain rate is immaterial, and gives them no greater right to bring the action than in places where no such custom is known. (Willcock, p. 3.) A physician however of great eminence may be considered reasonably entitled to a larger recompense than one who has not equal practice, after it has become publicly understood that he expects a larger fee; inasmuch as the party applying to him must be taken to have employed him with a knowledge of this circumstance. (*Ibid.*)

PHYSICIANS, ROYAL COLLEGE OF, the principal chartered medical body in England, was founded through the instrumentality of Linacre, who obtained, by his interest with Cardinal Wolsey, letters patent from Henry VIII., dated in the year 1518. This charter granted to John Chambre, Thomas Linacre, Ferdinand de Victoria, Nicholas Halsewell, John Francis, and Robert Yaxley, that they, and all men of the same faculty of and in the city of London, should be in fact and name one body and perpetual community or college; and that the same community or college might yearly and for ever elect and make some prudent man of that community expert in the faculty of medicine, president of the same college or community, to supervise, observe, and govern for that year the said college or community, and all men of the same faculty, and their affairs, and also that the president and college of the same community might elect four every year, who should have the supervision and scrutiny, &c. of all physicians within the precinct of London. The statute (14 Henry VIII.) confirmed this charter, and further ordained that the six persons above named, choosing to themselves two more of the said commonalty, should from henceforth be called and cleaped elects; and that the same elects should yearly choose one of them to be president of the said commonalty; and then provided for the election of others to supply the rooms and places of such elects as should in future be void by death or otherwise, which was to be made by the survivors of the same elects. The statute (32 Henry VIII.) provides that from thenceforth the President, Commons, and Fellows might yearly, at such time as they should think fit, elect and choose four persons of the said Commons and Fellows, of the best learned, wisest, and most discreet, such as they should think convenient, and have experience in the faculty of physic, to search and examine apothecaries' wares, &c. This last appointment is independent of the constitution of the body, the persons so appointed being officers for a special purpose; and it has been usual to select for this office the same four persons in whom the government of the physicians is reposed by the charter and statute of the 14th of that king.

The constituted officers then of this corporation are the eight elects, of whom one is to be president, and four governors, who have generally born the name of censors. There is nothing to be gathered from the charter or statutes in any way tending to exclude any of the elects, except the president, from the office of censor; and as no duties are assigned to the elects, except those of filling up their own number, electing one of themselves to be president, and granting testimonials to country practitioners, they may be rather regarded as candidates for the office of president than as active officers of the corporation. The college is bound to choose four censors, for the purpose of discharging the duties confided in it, which are to be executed by these officers. It is also incumbent on the elects to preserve their number, so that there may at no time be less than five, including the president, as they would not, after a further reduction, be capable either of electing a president or choosing others to fill the vacancies in their own body. (Willcock *On the Laws of the Medical Profession*, p. 32.) It is evident that the charter so far incorporated all persons of the same faculty, of and near London, that every person on the 23rd of September, in the 10th year of the reign of Henry VIII., falling within that description, was entitled to be admitted into the association. Such of them as had availed themselves of this privilege, and others subsequently admitted, are the persons described by statute 32 Henry VIII., as 'Commons and Fellows' (quoted in Willcock, p. 13). But as to the persons who should afterwards enjoy that distinction, the original charter and all subsequent statutes are silent. James I. and Charles II. granted charters to this body. The first is silent as to the mode of continuing it; but the charter of Charles, after limiting the number of fellows to forty, directed that when a vacancy should occur in that number, the remainder should elect one of the most learned and able persons skilled and experienced in physic, then of the commonalty of members of the college. Each of these charters seems to have been granted with a view to the enactment of a bill to the same effect, as the kings respectively pledged themselves to give it the royal assent. No statute has been at any time passed in pursuance of this purpose; and it is very doubtful how far and in what manner the charters have been accepted by the college, though they have certainly been several times acted upon. (Willcock, p. 34.)

The licentiates of the college who may practise within the precincts of London and seven miles round it were (until 1836) of three orders, viz. Fellows, Candidates, and mere Licentiates. The last of these classes, generally denominated licentiates, are those who have only a licence to practise physic within the precincts above described. The second class was abolished in 1836. The first class are those who have received that licence, but whose licence also shows that they are admitted to the order of fellows. This licence has often been called a *diploma*, but as it confers no degrees, the word is not properly applied, according to its more strict signification

The order of Licentiates was created by the following clause of the charter of Henry VIII.:—'We have granted also to the same President and College or Community, and their successors, that no one within the said city or within seven miles around it may practise in the said faculty until admitted to this by the said President and Community, or their successors for the time being, by the letters of the same President and College, sealed with their common seal, under the penalty of one hundred shillings for every month for which, unadmitted, he may have practised in the same faculty, half to be applied for us and our heirs, and half for the same President and College.' Now the common law having given every man a right to practise in any profession or business in which he is competent, the effect of 14 Henry VIII. must be taken to be this, viz. it has left to every man his common law right of practising in the profession of physic, as in any other profession, if competent, and has appointed the president and college to be judges of this competency. (Willcock, p. 38.) The mode of examination is wholly in the discretion of the college, which has confided the immediate direction of it to the censors. It has however also appointed that the doors of the censors' chamber shall be open to all fellows who may think proper to be present, and that they may take part in the examination, should they think fit; and that the fellows may have an opportunity of availing themselves of this right, it is appointed that all examinations shall take place at a court held at certain regular intervals. (*Ibid.*, p. 41.)

The order of Candidates was abolished in 1836, as above stated, but there were reserved to students then in the universities of Oxford and Cambridge their *inchoate* rights.

The order of Fellows comprises those who are admitted into the fellowship, community, commonalty, or society of the college. The charter incorporated all physicians then legally practising in London, so that each of them who thought proper to accept it became *ipso facto* a member or fellow; but as all future practitioners, within the precincts of and seven miles round that city, were required to obtain the licence of the college, there soon arose two orders of the profession. The fellows attempted by various bye-laws to limit their own number, but seem to have considered the licentiates as members of the college, or the commons, and themselves as forming a select body for the purpose of government. To this state of the society, the statute 32 Henry VIII. seems to allude in speaking of the 'commons and fellows.' The charter of Charles II. expressly notices these orders as forming the body of the society, inasmuch as it directed that new fellows should be elected from among the commons of the society. (*Ibid.*, p. 44.)

The following is a short account of the bye-laws of the college respecting the election of Fellows:—It was at first provided (anno 1555), that no one should be admitted into the college until he had practised for some time under a probationary licence, which time was afterwards limited to four years. This was perfectly reasonable and consistent, as affording a proper opportunity of making the candidate and his qualifications and title to precedence known to his electors. About the same time were established the three classes of fellows, candidates, and licentiates. In 1637, it was ordained that no person should be admitted a fellow until he had performed all his exercises and disputations in one of the 'British universities,' without dispensation; and in 1737, that none should be admitted into the society of the college who should not first have been of the number of candidates for one whole year, or have publicly read physic for three years in some 'university of Britain,' or been doctor of the chair in some university of this kingdom, or ordinary king's physician. In 1751, under the pretence of explaining the words 'any British university,' in some of the former bye-laws, it was declared that no person should be admitted who was not a doctor of physic of Oxford or Cambridge. Another alteration was introduced in 1765, by excluding all except such candidates, and the king's or queen's ordinary physician with salary, and the regius professors of physic of Oxford and Cambridge: and in or soon after the year 1768, it was declared that no person should be admitted to the order of candidates unless he had been created a doctor of physic in the university of Oxford or Cambridge, or, having obtained that degree in the university of Dublin, had been incorporated into the university of Oxford or Cambridge; and until he had been examined as to his knowledge of physic at three of the greater or lesser meetings of the college: and that no person might be admitted a fellow unless he had been a candidate for a year, except that the president might once in every other year propose at the comitia minora one licentiate of ten years' standing; and if the greater part of the comitia minora should consent, propose him at the next comitia majora to be elected a fellow; and if the greater part of the fellows then present should consent, such licentiate might be admitted a fellow; and that any of the fellows might propose a licentiate of seven years' standing, and of the age of thirty-six years, in the comitia majora to be examined; and, if the greater part of the fellows should consent, the licentiate might be examined by the president, or vice-president, and censors; and if approved by the greater part of the fellows then present, he might be proposed to the next comitia majora to be a fellow, and admitted, should the majority of fellows then present consent. (*Ibid.*, p. 46.)

These bye-laws are considered in law invalid, and are directly contrary to the original charter. The statute rendered all men of the faculty of and in London eligible to the fellowship: the bye-law says, all men of the faculty of and in London are not eligible, but those only who have been of the order of candidates for one year; and none can become candidates who are not graduates of Oxford or Cambridge. This is directly in the teeth of the statute: it is the imposing a qualification not required by the constitution; and (what is most fatal to such a qualification) one which does not depend upon the body imposing it, or any select portion of that body, but on two universities, in legal acceptation strangers to and unconnected with this college, and wholly overlooked by the statute by which it was established. (*Ibid.*, p. 49.)

It would be impossible here to give an account of all the literary controversies in which the College of Physicians have been continually engaged, partly in support of their own just and undoubted rights, and partly in defence of their arbitrary and unwise limitations with respect to the election of fellows. A list of the titles of more than fifty pamphlets, &c., written for or against the college between the years 1665 and 1810, is given in a work entitled 'An Exposition of the State of the Medical Profession in the British Dominions; and of the Injurious Effects of the Monopoly, by Usurpation, of the Royal College of Physicians in London,' 8vo., Lond., 1826, pp. 373. After much dispute and discussion, these obnoxious bye-laws have lately been repealed, and the following regulations have been published by authority of the college

Regulations of the Royal College of Physicians of London.

The College of Physicians, having for some years past found it necessary, from time to time, to make alterations in the terms on which it would admit candidates to examination, and license them to practise as physicians, has reason to believe that neither the character nor object of those alterations, nor even the extent of the powers with which it is invested, has been fully and properly understood.

The college therefore considers it right at this time to make public a statement of the means which it possesses, within itself, of conferring the rank and privileges of physician on all those who, having had the advantage of a liberal education, both general and professional, can prove their qualifications by producing proper testimonials and submitting to adequate examinations.

Regulations regarding Certificates and Testimonials.

Every candidate for a diploma in medicine, upon presenting himself for examination, shall produce satisfactory evidence, 1, of unimpeached moral character; 2, of having completed the twenty-sixth year of his age; and, 3, of having devoted himself for five years, at least, to the study of medicine.

The course of study thus ordered by the college comprises:—

Anatomy and physiology, the theory and practice of physic, forensic medicine, chemistry, materia medica and botany, and the principles of midwifery and surgery

With regard to practical medicine, the college considers it essential that each candidate shall have diligently attended, for three entire years, the physicians' practice of some general hospital in Great Britain or Ireland, containing at least one hundred beds, and having a regular establishment of physicians as well as surgeons.

Candidates who have been educated abroad will be required to show that, in addition to the full course of study already specified, they have diligently attended the physicians' practice in some general hospital in this country for at least twelve months.

Candidates who have already been engaged in practice, and have attained the age of forty years, but have not passed through the complete course of study above described, may be admitted to examination upon presenting to the censors' board such testimonials of character, general and professional, as shall be satisfactory to the college.

The first examination is in anatomy and physiology, and is understood to comprise a knowledge of such propositions in any of the physical sciences as have reference to the structure and functions of the human body.

The second examination includes all that relates to the causes and symptoms of diseases, and whatever portions of the collateral sciences may appear to belong to these subjects.

The third examination relates to the treatment of diseases, including a scientific knowledge of all the means used for that purpose.

The three examinations are held at separate meetings of the censors' board. The *vivâ voce* part of each is carried on in Latin, except when the board deems it expedient to put questions in English, and permits answers to be returned in the same language.

The college is desirous that all those who receive its diploma should have had such a previous education as would imply a competent knowledge of Greek, but it does not consider this indispensable if the other qualifications of the candidate prove satisfactory; it cannot however, on any account, dispense with a familiar knowledge of the Latin language, as constituting an essential part of a liberal education; at the commencement therefore of each oral examination, the candidate is called on to translate *vivâ voce* into Latin a passage from Hippocrates, Galen, or Aretæus; or, if he declines this, he is, at any rate, expected to construe into English a portion of the works of Celsus, or Sydenham, or some other Latin medical author.

In connection with the oral examinations, the candidate is required, on three separate days, to give written answers in English to questions on the different subjects enumerated above, and to translate in writing passages from Greek or Latin books relating to medicine.

Those who are approved at all these examinations will receive the following diploma under the common seal of the college:—

Sciant omnes, Nos, A. B. Præsidentem Collegii Medicorum Londinensis, unà cum consensû sociorum ejusdem, auctoritate nobis a domino rege et parliamento commissâ, examinâsse et approbâsse ornatissimum virum, T. S. et ei concessisse liberam facultatem et licentiam, tam docendi quam exercendi scientiam et artem medicam, eidemque summis honoribus et titulis et privilegiis, quæcunque hic vel alibi medicis concedi solent, intra auctoritatis nostræ limites frui dedisse. In cujus rei fidem et testimonium, adjectis censorum et registrarii chirographis, sigillum nostrum commune præsentibus apponi fecimus, datis ex ædibus collegii die ________________ mensis ________________ anno Domini millesimo octingentesimo ____________.

The college gives no particular rules as to the details of previous education, or the places where it is to be obtained. It will be obvious however, from a reference to the character and extent of the study above described, the manner in which the examinations are conducted, and the mature age of the candidates, as affording full time for acquiring the necessary knowledge, that there will be ample security afforded to the public and the profession, that none but those who have had a liberal and learned education can presume, with the slightest hope of success, to offer themselves for approval to the censors' board: and as the college trusts that, by a faithful discharge of its own duty, it can promise itself the satisfaction of thus continuing to admit into the order of English physicians a body of men who shall do it honour by their qualifications, both general and professional, it is prepared to regard in the same light, and address by the same appellation, all who have obtained its diploma, whether they have graduated elsewhere or not.

In drawing up and promulgating the above regulations, the college has endeavoured fairly to look at that which is substantial, rather than that which is merely nominal, in all that concerns the qualifications of its members; it has resolved to estimate all testimonials, whether they are presented under the name of certificates, diplomas, or degrees, strictly with reference to their value, and to measure them by this standard alone, as parts of the previous qualification of candidates, which they are to verify in their examinations.

The college feels confident that it has overstepped neither the spirit nor letter of the laws which have invested it with the power of governing and legislating for the whole faculty of medicine within its jurisdiction, by thus earnestly endeavouring to maintain its character and reputation, and vindicate its claim to be the source of professional honour.

Dec. 22, 1838. FRANCIS HAWKINS, *Registrar.*

Much curious information respecting the antiquities of the College of Physicians is to be found in 'The Gold-headed Cane,' an amusing and interesting little volume by the late Dr. Macmichael. He tells us (p. 120) that its very first meetings immediately after its establishment, 1518, were held in the house of Linacre, called the Stone House, No. 5, Knight Rider Street, which still belongs to the college. About the time of the accession of Charles I., the college removed to another spot, and took a house of the dean and chapter of St. Paul's, at the bottom of Amen Corner. During the civil wars, their premises were condemned, as part of the property of the church, and sold by public auction; on which occasion, Dr. Hamey became the purchaser, and two years afterwards, 1649, gave them in perpetuity to his colleagues. The great fire of London, 1666, consumed the college, and the whole of the library with the exception of one hundred and twelve folio volumes. For the next few years, the meetings of the fellows were generally held at the house of the president, while a new college was being built on a piece of ground that had been bought in Warwick Lane. This was completed in four years, and was opened, without any particular ceremony, on the 25th of February, 1674, under the presidency of Sir George Ent. Here the fellows continued to hold their meetings till within a few years, when (as Dr. Macmichael says) 'the change of fashion having overcome the *genius loci,*' the present new college, at the north-west corner of Trafalgar Square, was opened on the 25th of June, 1825, and an elegant Latin oration was delivered by the president, Sir Henry Halford.

PHYSICS. The word *phy'sike* (φυσική), or science of nature, might include in one general term all that is called mixed mathematics, natural philosophy, chemistry, and natural history. The title of physician, or student of nature, has become in our language synonymous with one who investigates the origin of diseases and the means of cure; but in the continental languages it still retains the more general signification. Also physic (the study of nature) has come to mean the drugs given to cure disorders, or medicines; and it would be difficult to name two more complete departures from etymology.

The plural physics is always used to mean the study of nature by means of the severer modes of investigation. Some apply it to the application of mathematics to material phenomena, and to this alone; others, distinguishing the preceding as mathematical physics, include under the general term the sciences of experiment. There is no usage which in any degree approaches a universal reception; we prefer the second-mentioned signification.

PHYSIOGNOMY (φυσιογνωμονία) is the art of determining the mental character of an individual by the examination of his countenance. The popular ideas of the indications afforded by different kinds of features, by the adoption of which almost every one is at times a practitioner of physiognomy, are nearly as definite as the few principles which those who have made it an object of peculiar study have established. The circumstance on which the chief and surest indications afforded by the countenance depend, is, that when certain feelings and habits are much indulged in, the positions of the features which are associated with them are apt to become permanent, either by the formation of wrinkles or other marks in the skin, or by the enlargement and disproportionate strength of the muscles chiefly exerted. Thus a person in the frequent habit of sneering contemptuously acquires at last a slight curve in his upper lip by the disproportionate size and power of its elevator muscle; he who is often meditating has the wrinkles of the slight frown and the contraction of the brows which are commonly associated with deep thought, permanently fixed; he who has his attention constantly alive to the objects around him acquires an expression of vivacity in the openness of his eye and the quickness of the motions of all the muscles of his face; while he, on the other hand, whose thoughts are rarely roused to active efforts, acquires a smoothness of feature and a sluggishness of action in the several parts of the face, which indicate that its muscles have been exercised as rarely and with as little energy as his thoughts.

The peculiarities of feature thus acquired are often transmitted from the parent to the child; and in the latter, their indications will be correct or false according as there has or has not been a coincident transmission of the parent's disposition. Or a child may acquire a peculiar expression of countenance by imitating those among whom it is placed, and in this case also it will only be by accidental coincidence that the indications of the features are correct. From these and other sources of fallacy, the attempts to raise physiognomy into a science have not been so successful as to encourage a deeper study of it than every one unconsciously engages in during his intercourse with the world.

PHYSIOLOGY (φυσιολογία, from φύσις, nature, and λόγος, discourse) is the science which treats of the phenomena of living bodies. Its several departments are considered in separate articles, in which a complete system may be found in those on LIFE, DIGESTION, ABSORPTION, CIRCULATION (HEART), RESPIRATION, NUTRITION, SECRETION (GLAND), BONE, SKELETON, ARTICULATION, MUSCLE, LARYNX, NERVE, BRAIN, the several organs of the SENSES, EMBRYO, OVULE, and the articles on the anatomy and special physiology of the individual organs of animals and plants, which are referred to in each of the preceding.

PHYSO'GRADA, a family of marine animals, arranged by M. de Blainville, in his synoptic table, under the *Zoophytes*, but as one of the aberrant or false forms of that class, and as animals improperly referred to them.

These *Physograda*, according to M. de Blainville, have a regular, symmetrical, bilateral, contractile, fleshy body, often very long, provided with a complete intestinal canal, with a more or less considerable aëriferous dilatation; there are a mouth and anus, each of them terminal, and anomalous branchiæ in the form of very long, very contractile cirrhi, intermingled with the ovaries.

M. de Blainville remarks that the animals which constitute this group are so anomalous at first sight—they seem to recede so much from known types, that it is difficult to form anything like a satisfactory idea concerning them. Zoologists therefore who have followed the natural method, were obliged, in placing them among the radiated animals, to make of them a particular section, under the name of anomalous or irregular *Radiata*; and in truth very anomalous *Radiata* they were, having nothing about them of a radiated disposition of structure.

Another reason which contributes to the difficulty of following out the relations of the *Physograda*, is the rarity of finding them in an unmutilated state, and above all because it is almost impossible to preserve them in collections, so frail and delicate is their structure. Even when consigned to the spirit in a perfect state, they become so changed from contraction, that their natural form and structure are scarcely to be recognised.

M. de Blainville further observes that he had long entertained grave doubts as to the place assigned to those animals in the zoölogical scale, founded solely on external form, which, according to his principles, is sufficient to determine the degree of organization of an animal; but he had not succeeded in elucidating them completely up to the time when MM. Quoy and Gaimard submitted to his observation many specimens of the common *Physalus*, and M. Hérissier de Gerville sent him an individual tolerably perfect, freshly preserved in spirit of wine. Since then M. de Blainville had opportunities of observing some specimens of *Physsophora* and *Stephanomia*, also communicated to him by MM. Quoy and Gaimard; so that he thinks he is able to withdraw all these animals from the type of the *Actinozaria*, to form a distinct order of them under the type of *Malacozoaria*. Nevertheless, he observes, the *Stephanomiæ* may not belong to the same family as the *Physsophoræ* properly so called.

The authors, says M. de Blainville, in continuation, who have spoken of the animals that constitute this order, are rather numerous; but only a small number of those authors have examined them, and that incompletely. The *Physali* were first observed, and from the time of Browne,* who first figured them, down to M. Lesson, who published some new ones in the Atlas, illustrating the voyage round the world by Captain Duperrey, there are few voyagers who have not noticed them. Forskael seems to have known the *Physsophoræ* best; but these have been least observed. The *Stephanomiæ* were discovered by Péron and Lesueur; but the individuals from which they characterised the genera were incomplete. The work of MM. Quoy and Gaimard on the *Physsophoræ* was addressed to the Academy of Sciences at Paris, during their last voyage in the Astrolabe, commanded by Captain d'Urville.

It is by the aid of these different works, and especially from the means generously afforded to M. de Blainville by MM. Quoy and Gaimard that he has produced the arrangement which we proceed to lay before our readers. (*Actinologie*, 1834.)

But before we enter upon the divisions and subdivisions it will be necessary to apprise the reader that very great obscurity still veils much of the organization of these animals, that part of it especially which relates to the propagation of the species. It is now well known, through the labours of some distinguished continental zoologists, that several of the *Medusæ*, probably all, are diœcious [PULMOGRADA]; but the generation of the group before us is not yet satisfactorily made out; at least after some research we cannot find that it is. We now turn to M. de Blainville's arrangement.

*

Natatory organ simple and lamellar.

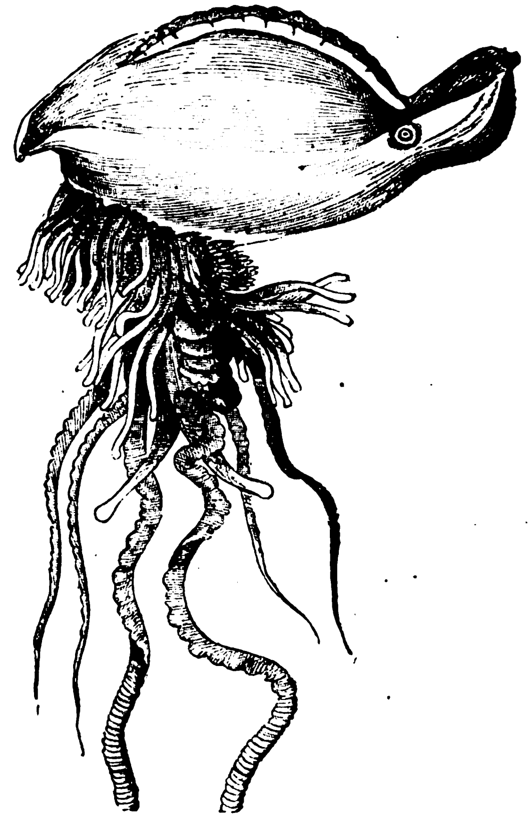
Physalia.

Generic Character.—*Body* oval, rather elongated, more narrow and proboscidiform anteriorly, hydatiform in the middle, attenuated and obtuse posteriorly, mouth star-shaped and terminal; anus lateral; a foot in form of a crest or oblique lamina, directed from before backwards; branchiæ very anomalous, and composed of a great number of diversiform cirrhous productions; organs of generation terminating at the anterior third of the right side by two closely approximated orifices. (De Blainville.)

As to the molluscous relationship and the organs of generation—*quære*.

Example, *Physalia Arethusa*.

This is the *Aretusa* of Browne; *Medusa Caravella* of Müller and Escholtz; *Physalus pelagicus* of Lamarck; the Portuguese man-of-war of English voyagers. When the crest is expanded it has been very probably mistaken for Argonauta Argo, the Paper Nautilus, by those who have declared that they have seen fleets of the latter sailing. This *Physalus* is an inhabitant of the warm seas, but a shoal of them are sometimes driven into our bays, particularly on the south-west coast. 'When we were in about 46° of



Physalus pelagicus: the crest not expanded.

---

* Sloane?

northern latitude,' says Sloane, in his 'Voyage to Jamaica,' 'I first saw what the seamen call a *Caravel*, or *Portuguese* man-of-war, which seems to be a *zoophytum*, or of a middle nature between a plant and an animal; it is of that kind of the soft fishes called *Urticæ*, from their stinging quality, and to me seems different from any described by any natural historian. I shall call it *Urtica marina, soluta, purpurea, oblonga, cirrhis longissimis;* and he figures it with the crest or lamina expanded as '*A. carvell.*,' plate iii., *fig.* 5.

* *

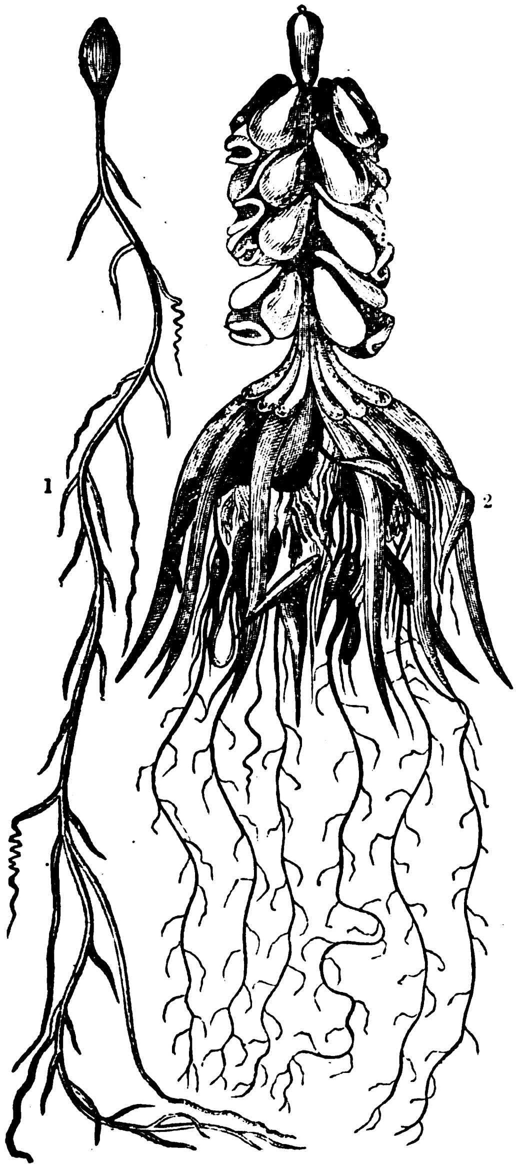
Locomotive organs complex and vesicular.

Physsophora.

Generic Character.—Body more or less elongated, cylindroïd, hydatiform in its anterior part, provided below with two series of vesicular diversiform bodies, with a regular aperture, and behind with a variable number of very diverse cirrhiform productions, two of which are longer and more complex than others; mouth at the extremity of the hydatiform part; anus terminal; organ of generation? (De Blainville.)

Example, *Physsophora Muzonema.*

M. de Blainville states that the *Physsophoræ* differ from the *Physali* in swimming or floating in a vertical position, the aëriferous pouch being above and the cirrhiferous productions below. The distinction of the species appears to him to depend especially on the number and form of the natatory organs.



1. Rhizophysa filiformis; 2, Physsophora Muzonema.

Diphysa.

Generic Character.—Body cylindrical, elongated, contractile, muscular, composed of three parts, the anterior part vesicular, the middle part bearing on its lower part two hollow natatory organs, placed one before the other, and the third part (which is the longest) provided above with a fibrillo-capillaceous plate, and below with cirrhiform productions; mouth terminal; anus? (De Blainville.)

Example, *Diphysa singularis* (Quoy and Gaimard; *Astrolabe, Zoologie*).

Rhizophysa.

Generic Character.—Body free, transparent, very contractile, very much elongated, swollen at one extremity into a sort of aëriferous bladder with a terminal orifice, provided throughout its length with scattered tentaculiform productions mingled with cirrhiform filaments. (De Blainville.)

This genus is divided by M. de Blainville into two sections.

1.

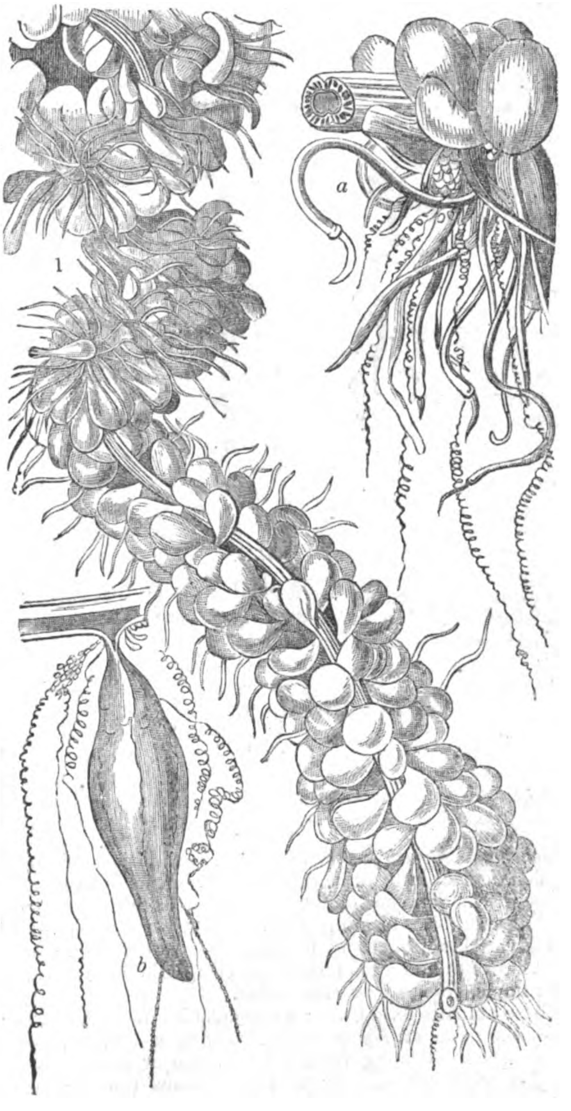
Species with simple tentaculiform productions. Natatory organs hollow. (Genus *Rhizophysa.*)

Example, *Rhizophysa planostoma*, Péron; (*Rhizophysa Péronii*, Esch., *Acaleph.*, p. 148, No. ii., t. 13, *fig.* 3).

2.

Species whose tentaculiform productions are covered with cirrhiform filaments. Natatory organs unknown. (Genus *Epibulia*, Esch.)

Example, *Rhizophysa filiformis* (*Physsophora filiformis*, Forsk.), represented above.



1, a portion of Apolemia Urania.
2 a part still more highly magnified; *b*, a single sucker.

* * *

Species provided with two sorts of locomotive organs, the anterior ones hollow, the posterior solid.

Apolemia.

Generic Character.—Body very much elongated, cylindrical, vermiform, provided anteriorly with many hollow natatory organs in two rows, and behind with solid squamous organs, between which come forth tentaculiform cirrhi, furnished with vermiform suckers.

Example, *Apolemia Urania.*

Stephanomia.

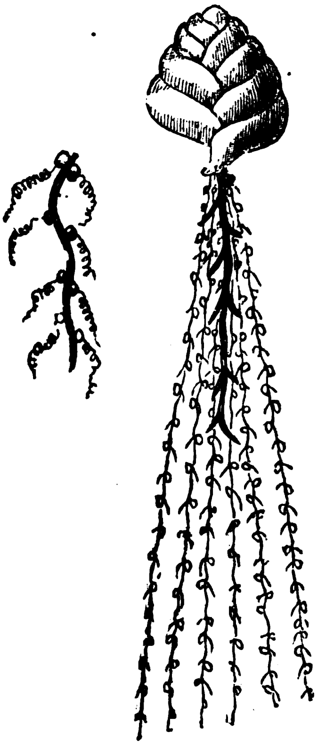
Generic Character.—Body in general very much elongated, cylindrical, vermiform, covered throughout its extent, except in the lower median line, with squamous natatory organs, full and dispersed in transverse bands, between which come forth, and especially inferiorly, long, very much diversified cirrhiform productions, mingled with the ovaries. Orifices of the intestinal canal terminal. (De Blainville.)

Example, *Stephanomia Amphitrides*, Péron et Lesueur (*Voyage aux Terres Austr.*, p. 45, pl. 29, *fig.* 5).

Protomedea

Generic Character.—Body free, floating, cylindrical, fistulous, very long, provided above with an imbricated assemblage of gelatinous bodies (on two alternate rows) which are full and hippopodiform, and throughout the rest of its length with filamentous, cirrhous, diversiform productions. Mouth proboscidiform, at the extremity of a sort of vesicular stomach.

Example, *Protomedea lutea.*



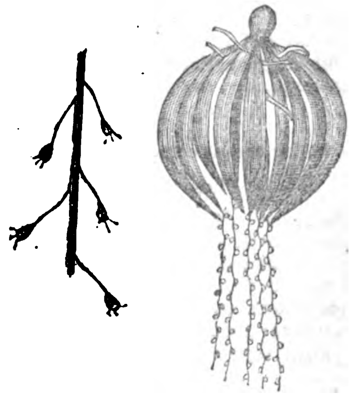
Protomedea lutea.

Rhodophysa.

Generic Character.—Body short, cylindrical, fleshy, swollen above into an aëriferous bladder, and provided below with a variable number of gelatinous bodies, which are full, costiform, forming a single transverse series, and with a variable number of filamentous diversiform productions. Mouth and anus terminal. (De Blainville.)

Example, *Rhizophysa Helianthus.*

These animals form Cuvier's second order of Acalephans, under the name of *Hydrostatic Acalephans*. He characterises them as being recognised by one or two ordinary vesicles filled with the air, by whose means they are suspended in the water. Appendages singularly numerous and varied in form, some of which probably serve as suckers, others perhaps as ovaries, and some, longer than the others, as tentacula, are joined to these vesicular parts to compose the whole apparent organization of the animal. Cuvier adds that it is not observed whether they have a mouth well distinguishable as such. (*Règne Animal*, 1830.)

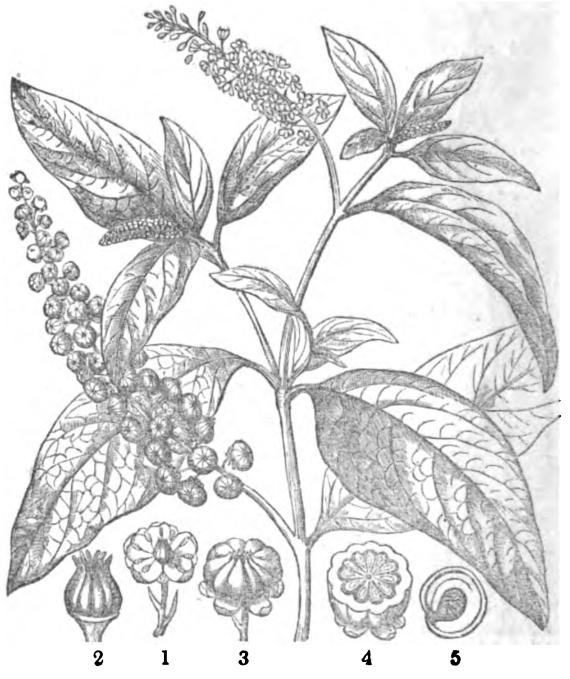


Rhodophysa Helianthus.

PHYSSO'PHORA. [Physograda.]

PHYTO'CRINUS. [Encrinites, vol. ix., p. 391.]

PHYTOLACCA, a genus of tropical or subtropical herbaceous plants, with erect or occasionally twining stems, a thickish turnip-shaped root, alternate undivided broad leaves, and leafless erect racemes of flowers succeeded by deep purple fruits. They have a five-parted calyx, no corolla, from five to thirty stamens inserted into a fleshy disk, and the pistil consists of several unilocular distinct carpels united at the base or along the whole inner angle. The fruit is an umbonate depressed berry, with solitary seeds whose embryo is turned round mealy albumen. *Phytolacca decandra*, a species found wild in Virginia, where it is called Pocan, whence the vulgar name of Poke applied to this species, has a root which acts as a powerful emetic, but its exhibition is attended with narcotic effects: its berries are also reported to possess the same quality; they stain an intense purple colour, and are said to be employed in Portugal as a means of improving the appearance of inferior red wines. Notwithstanding the acridity of its leaves, this plant, when very young, is said to be eaten in the United States as asparagus; and Dr. Royle relates that he found *P. acinosa*, a Himalayan species, employed in the same manner in the north of India, to be very palatable when boiled.



Phytolacca decandra.

1, an expanded flower; 2, the pistil; 3, a ripe fruit; 4, the same, cut through transversely; 5, a vetical section of a seed.

PHYTOLACCA'CEÆ form a small natural order of plants, named after the subject of our last article, but whose limits and position in a natural series are unsettled. According to most writers they are regarded as apetalous plants and allies of the Chenopodiaceous and Polygonaceous orders, from which their distinct ovaries chiefly distinguish them. But Endlicher, in his recent arrangement of plants, probably influenced by the form of their embryo, and by the plurality of the carpels, considers them as related on the one hand to the Caryophyllaceous, and on the other to the Malvaceous orders. Notwithstanding the apparent difference between these two stations, it is probable that both are correct, and that Phytolaccaceæ are really plants connecting Chenopodiaceæ and Caryophyllaceæ. If so, they furnish a new proof of the badness of the fundamental divisions proposed for Exogens by both De Candolle and Jussieu. With the exception of Phytolacca, no plants of this order appear to be of much importance to man; their properties seem to be generally acrid.

PHYTOSAU'RUS, Jaeger's name for a genus of fossil Saurians. Two species are recorded, *Phytosaurus Cubicodon*, and *Ph. Cylindricodon*, both from the dolomitic sandstone (Keuper formation).

PHYTO'TOMA. [MUSOPHAGIDÆ, vol. xvi., p. 28.]

PHYTOTOMI'NÆ. [MUSOPHAGIDÆ, vol. xvi., p. 28.]

PHYTOZOA'RIA. This is the general term employed by M. Ehrenberg to include the numerous species and genera of minute animals living in water, for which by other writers the titles of Infusoria and Microzoaria are preferred. There are two grand divisions, or classes as Ehrenberg calls them, of the Phytozoaria, viz. Polygastrica and Rotatoria or Rotifera; and as, judging from some examination, and in accordance with many modern writers, we consider these classes to be really and widely distinct, so as to deserve to be placed in very different parts of the scale of animal organization, we treat the subject under those terms respectively. [INFUSORIA; MICROZOARIA; POLYGASTRICA; ROTATORIA.]

PHYZE'LIA, one of the divisions of the *Terebelles* of Savigny (*Amphitrite*, Cuv., part; *Annelides Tubicoles* of Cuv.).

PIA MATER. [BRAIN.]

PIACENZA (*Placentia*), a town in the duchy of Parma, and the second in importance in that state, is situated about half a mile from the southern bank of the Po, and two miles east of the confluence of the Trebbia with that river, in a fine plain bounded on the south by well cultivated hills. The town is surrounded by walls and ditches, and has a citadel, which, according to a stipulation of the Congress of Vienna of 1815, is garrisoned by Austrian troops. The streets are wide and straight. The principal square in front of the ducal palace is adorned with two equestrian bronze statues of dukes Ranuccio and Alessandro Farnese. Piacenza abounds in fine buildings, the principal of which are—1, the ducal palace, commenced after the design of Vignola, but not finished; 2, the Podesteria, or town-house, a Gothic building of the thirteenth century; 3, the cathedral, a handsome Gothic structure of the twelfth century, with fresco paintings by Guercino and Luigi Caracci; 4, S. Sisto, a handsome church, richly adorned; 5, the fine church of S. Agostino; 6, Santa Maria di Campagna, which belongs to the Franciscan friars, has some fine paintings. The town library contains 30,000 volumes; the new theatre, and the school of design and architecture, are also worthy of notice.

Piacenza contains 25,000 inhabitants, who carry on a considerable trade in the agricultural products of the country. The establishments for public instruction consist of a superior school, or lyceum, with professors of law and medicine; a secondary or grammar school, the college Alberoni for boarders, a school of the fine arts, an institution for the education of young ladies, and several elementary schools for boys and girls.

Placentia is first mentioned as being a Roman colony, settled at the same time as Cremona, in the country conquered from the Gauls, in the year 224 B.C. (Livy, *Epitome*, xx.) In the second Punic war it was besieged unsuccessfully by Hasdrubal while on his march to join his brother Hannibal; but after the end of that war it was taken and destroyed by a band of Ligurians and Gauls, headed by Hamilcar, a Carthaginian officer, who had remained behind after the defeat of Hasdrubal, and had succeeded in organising the mountaineers of the Ligurian Apennines, and leading them against the Romans. (Livy, xxxi. 10.) After the defeat and death of Hamilcar by the Roman prætor L. Furius Purpureus, the colony of Placentia was restored. Tacitus (*Histor.*, ii. 21) mentions Placentia as being gallantly defended by Spurinna, a captain of Vitellius, against the attack of Cæcina, one of Otho's generals, on which occasion a splendid amphitheatre, which stood outside of the walls, was destroyed. It was near Placentia that the Roman troops under Aurelianus were defeated in a great battle by the Marcomanni, who had invaded Upper Italy, but Aurelianus afterwards defeated and exterminated the invaders, A.D. 271.

In modern history Piacenza is mentioned as one of the independent Lombard cities. It afterwards had its lords or tyrants of the families of Pelavicino or Pallavicino, Scotti, and Landi. It next fell under the dominion of the Visconti dukes of Milan. After the death of Filippo Maria Visconti, A.D. 1447, and the establishment of an ephemeral republic at Milan, the citizens of Piacenza revolted against the Milanese, and placed themselves under the protection of Venice. But Francesco Sforza, being appointed commander of the Milanese, retook Piacenza, in December, 1447, when the town was given up to pillage. The soldiers of Sforza committed all sorts of violence and cruelty, sparing neither age nor sex; even the churches were not respected. The Milanese historians Corio and Simoneta fully relate those atrocities. From that time Piacenza never recovered its former prosperity: it remained subject to the Sforza dukes of Milan, was taken by the French under Louis XII., and retaken from the French by pope Julius II., after which it remained subject to the popes, together with Parma, until 1545, when pope Paul III. gave it to his son Pier Luigi Farnese. From that time it has formed part of the duchy of Parma.

Piacenza has produced many distinguished men: the scholar Valla, pope Gregory X., Cardinal Alberoni, Gio. Battista Porta, the economist Gioia, the philologist Giordani, and others who are noticed by Poggiali, 'Memorie per la Storia Letteraria di Piacenza,' 2 vols. 4to., 1778; and in the 'Memorie Storiche della Città di Piacenza,' by the same writer. A description of the buildings and other objects worthy of notice was published in 1828: 'Descrizione dei Monumenti e Pitture di Piacenza,' 8vo.

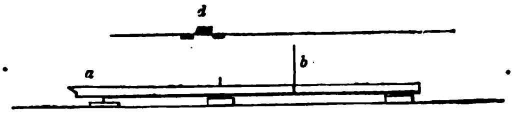
PIAHAU, or PIAUHAU, the name assigned to certain *Cotingas* (*Ampelis*, Linn.), whose bill is more strong and more pointed than the ordinary *Cotingas*. The *Piauhaus* are so called from their cry, and are very insectivorous. Vieillot has distinguished them by the generic name of *Querula*. [MUSCICAPIDÆ, vol. xvi., p. 11.]

PIANO-FORTE, a keyed musical instrument, variously formed and under different denominations, such as *grand*, *square*, and *upright*. The first notion of the square piano-forte was taken from the clavichord by a German mechanic of the name of Viator, about ninety or a hundred years ago; but, for want of friends or funds, he never became known as a maker. The invention however was followed up by other musical instrument makers of the same nation, who all left their clavichords and harpsichords for the new instrument, the piano-forte. Thus we have Zumpe, Tabel, Schudi, Kirkman, Broadwood, Stodart, Schoene, Buntebart, Pohlman, Pether, Beck, Garcha, Ganer, and a host of others.

The grand piano-forte is supposed to be of earlier date than the square piano-forte, and is said to have been the invention of a German musician of the name of Schröder, or, as others say, of Christofali, a harpsichord-maker of Padua. The first maker at all known in this country was a German of the name of Backers, but we are not aware that success attended his exertions with the solid advantages which were enjoyed by his contemporary Zumpe, who realised an ample fortune, and retired. The place of his retirement we well remember, and have heard good report of his cheerful glass and well-filled pipe, without which, in those days, a German did not acknowledge that he lived. The grand piano-forte retains the shape of the instrument from which it was taken, the harpsichord; and although that shape has been much condemned, we have never been able to see any other objection to it than its largeness; it is the natural outline of the instrument, and we do not think that a better form for it will ever be devised.

The square piano-forte, we have said, was taken from the clavichord, but it retains only its shape, with the same disposition of the strings and keys; their actions have no similarity. The action of the clavichord was simply a piece of brass pin wire, which was placed vertically at a point where it could be struck or pressed against its proper string, the right-hand division of which was free to vibrate, whilst the left-hand was muffled by a piece of cloth, the object of which was to damp or stop the string, which it did the instant the finger was taken off the key. The touch of the clavichord was peculiar, partaking both of the harpsichord and the organ; in other words, both *struck* and *pressed*, and the pressure could be so varied as to produce a kind of tremblant effect. The tones were feeble, soft, and melancholy, and better suited to the student, the composer, or the solitary, than any purposes of social amusement.

Fig. 1.



a, Key. *b*, Brass pin wire. *c*, String. *d*, Cloth woven between the strings as a damper.

The action of the square piano-forte, on its first introduction, consisted of a *key*, a *lifter*, a *hammer*, and a *damper*. The key was the same as that of the clavichord. The lifter was a brass wire, with a piece of hide leather as a head, which was covered with a piece of soft leather as a finish. This lifter, when in motion, struck the hammer against the string, and thus produced the tone of the instrument. The damper followed the performer, and stopped the vibrations as quickly as the finger was removed from the key. (See *fig.* 2.) The tone of this piano-forte was thin and *wiry*, the hammer having only one slight covering of sheep-skin leather upon it.

Fig. 2.

This rude idea of a piano-forte continued in use for many years, and the first improvement upon it was introduced by Longman and Broderip, who brought out a patented invention having two additional parts in the action, namely, the *hopper* and the *under-hammer*, as they were called (see *fig.* 3). This patent was followed by another introduced by Clementi and Co., the burden of which simply was an improvement on the damper. It was called the *Irish patent*, from its having been the invention of an Irishman of the name of Southwell; but it had simplicity only to recommend it, was found inconvenient, and shortly afterwards was superseded by what is now called the *crank* damper. We cannot give the name of the inventor of this improvement; it became so instantaneously general, that the inventor was lost sight of in the crowd of makers who adopted his invention. It is still in use, and is acknowledged to be a good and sufficient plan. The damper used by Messrs. Broadwood previously to the introduction of the crank damper was made in brass (see *fig.* 2), but by whom invented we do not know. We now come to the last addition which has been made to the action of the square piano-forte, the *check*. This member was borrowed from the grand piano-forte, and is so acknowledged by the name given to those square piano-fortes which have it; for they are always called, par excellence, *grand-square piano-fortes*. The check certainly is a most important part of a piano-forte, and the best of actions is nothing without it. The check is placed behind the hammer, nearly at the end of the key; where, after the blow has been given, it catches the tail of the hammer, and holds it till another blow is required (see *fig.* 3). For further information as to the square piano-forte, we refer to the diagrams, which we hope will be found sufficient for any information that may be required. As an instrument, we think less of the square piano-forte than any other: it has neither the touch, the tone, nor the appearance of either the grand or the upright.

Fig. 3, *exhibiting all the Varieties of the modern Square Piano-forte as respects the Action.*

Fig. 3.

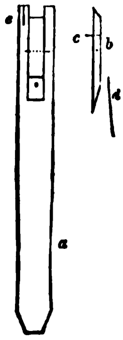
The grand piano-forte, as above observed, was the invention of Schröder or Christofali, manufactured by Backers, and retains the shape of the instrument from which it was taken, the harpsichord. Here again we have two instruments alike in *form*, but unlike in almost every other circumstance; for their action, their tones, and the style in which they are played upon, are all entirely different. The action of the harpsichord was simply a key and what was called a *jack*, which was a piece of pear-tree with a small moveable tongue of holly, through which a cutting of crow-quill was passed to touch the string when the jack was in action; the tone produced by this contrivance was a kind of *scratch* with a sound at the end of it (see *fig.* 4).

Fig. 4. *Harpsichord Jack.*

Fig. 4.



a, Jack. *b*, Tongue. *c*, Quill. *d*, Bristle spring. *e*, Cloth damper.

The action of a grand piano-forte consisted of a *key*, a *lever*, a *hammer*, a *button*, a *check*, and a *damper*, with rails and sockets to connect them. By this combination of parts, every musical intention known or desired at that time was perfectly attainable, and with admirable effects by Mozart, Haydn, Cramer, and others (see *fig.* 5). But we have now new and more severe judges to encounter: former actions are no longer sufficient; new effects are to be given, and new powers are called for. Fortunately, these things have been accomplished, for new actions have risen up in abundance, and we have only to choose between them. The more or less of excellence will, doubtless, occasionally puzzle the amateur, but some ready-fingered friend or acquaintance may be called in, and the difficulty is instantly removed by a single cadence on the instrument desired; whether major or minor is quite immaterial.

No musical instrument is so universally admired as the piano-forte. Its compass, whether six octaves, six and a half, or seven, is sufficient for all purposes of musical composition, and may really be considered a miniature orchestra. The smaller instruments have generally only six octaves, the grands have six octaves and a half; seven octaves we have not yet learned to admire. The strings of the early piano-fortes were partly of steel and partly of brass, the treble notes of steel, and the lower notes of brass, a few of which, in the bass, were over-lapped or covered, rather open, with plated copper-wire to give them more gravity according to the length attainable in the instrument. But modern piano-fortes have steel wire throughout, with about an octave in the bass closely lapped with unwashed copper wire. The strings which are now used in piano-fortes are considerably larger than those which were formerly used; the advantages of which are durability and firmness. The steel-wire now in use is the manufacture of Mr. Webster of Penns, near Birmingham, and is greatly superior to the once-famed German wire, now no more in esteem with English manufacturers, from the bad quality of the metal and the very imperfect manner in which it was drawn: when perfectly round, which it ought always to be, it was generally too soft; and when sufficiently hard, it was scarcely ever well manufactured, from which circumstance it was constantly false in vibration. Stops and pedals are more or less adopted in different countries. Stops can scarcely be said to be used at the present day; they properly belong to the middle age of piano-forte making, and were placed in the instrument on the left hand of the performer. The damper-stop and the buff-stop were the most common; the damper-stop raised the dampers from the strings, which gave continuation to the tones, and the buff-stop raised a piece of soft buff leather up to the strings, and gave the instrument somewhat the tone of the harp. Pedals are much esteemed by some performers and little by others; in foreign piano-fortes we find many pedals, but in the English we have scarcely ever more than two—one for piano effects, and the other for forte. This pedal, the forte, is an effective pedal, and not at all injurious to the mechanism of the instrument; we cannot say as much of the piano pedal, for, by passing the action to one string, it is not only straining to the centres of the hammers, but is also very apt to disturb the tuning of the unisons, by which an instrument is often unfairly tested as regards its standing, and a more frequent application to the tuner is required. In lieu of this pedal, some makers have introduced a soft substance, wool or leather, between the hammers and the strings, by which something like the buff-stop is accomplished, but with more delicacy and vibration in its effects. The foreign name for this pedal is *jeu céleste*, and to us it is more agreeable, and is certainly less injurious to the action of the instrument than the more frequent piano pedal.

We will here give, in alphabetical order, a few diagrams of grand actions. Their merits we must leave to those who have occasion for them, reserving only the right to make a few brief remarks that may be necessary for the purpose of this article. They are the works of living manufacturers.

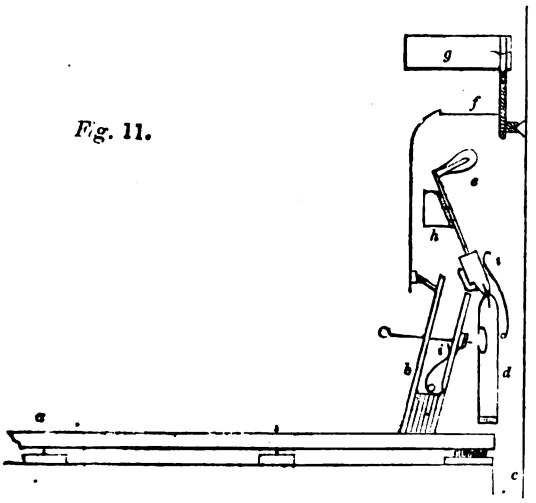
The upright piano-forte was, doubtless, taken from the upright harpsichord, and we have always understood that it was the invention of an Englishman of the name of Hancock, a musical instrument maker resident in some part of Westminster. He was a man of much ingenuity, and produced several varieties in keyed instruments; amongst which we find the *organised piano-forte,* the *portable grand* piano-forte, and an instrument, also a piano-forte, in the shape of a *spinnet.* The portable grand, in its day, was a successful and desirable instrument, but has long since been superseded by instruments of the kind called *kit* grands, *boudoir* grands, *pocket* grands, and *semi* grands. The next novelty was the invention of John Isaac Hawkins, who constructed an upright instrument with a detached sound-board in an iron frame, and the whole was so arranged as to be able to meet the atmosphere with compensating powers. In the bass, it had spiral or helical strings, by which length was gained; and, in the treble, three octaves of equal tension were accomplished by a uniform size of wire. It was patented, but did not take with the public sufficiently to come into notice. Following Hawkins we had William Southwell, who patented an improvement in upright piano-fortes, and gave it the name of the *cabinet piano-forte*. The name still remains amongst us, but the invention has long since been superseded and laid aside. The unique piano-forte was introduced about thirty years ago by Messrs. Wilkinson and Wornum, and was the invention and patent of the latter. This instrument met the taste of the day for instruments of *little altitude;* it did not stand higher than *three feet three inches*, and the strings were all placed *diagonally* towards the floor; the action was simple and effective, but it is not now under manufacture.

Fig. 11. *Mr. Wornum's Patent Unique Action.*

Fig. 11.



a, Key. *b*, Hopper. *c*, String. *d*, Hammer rail. *e*, Hammer. *f*, Damper and wire. *g*, Damper rail. *h*, Ruler. *ii*, Springs.

Numerous inventions and improvements appeared about this time, some of which were patented, and some not; but we cannot say more concerning them than that they were productions with scarcely a difference, and calculated merely to gratify their several makers with a variety of their own; for their powers and peculiarities were all much to the same effect under the finger of a performer: indeed we had no decidedly new thing until the double or Piccolo action appeared. This was the invention of Mr. Wornum, and patented by him some ten or twelve years ago; it is applicable to both upright and horizontal instruments, and is now extensively manufactured in Europe and America.

For delicacy, promptness, and firmness of touch, it has not yet been equalled.

There are many things relating to the piano-forte which we have not touched upon. There are also some foreign actions to which we have not given much attention, especially those called *down-striking* actions: we have seen these, but are decidedly of opinion that they never will receive sufficient approbation to come into general use: they are much lumbered with parts, and all have a bad touch, which, in the present age of performers, whose effects are so delicate and so rapid, is alone enough to condemn them. Other inventions too, such as Mr. Litherland's patent helical springs to preserve the tuning, Mr. Riley's transposing instrument, Mr. Mott's sostinente, Mr. Kirkman's octave string, and Mr. John Trotter's alternated key-board, have all given place to other things, and are no longer known to the present generation of musical people. Mr. Litherland's plan was a well-tempered *helical spring*, which was to be attached to the loop of the string; thus, as the string contracted the spring gave way, or as it expanded the spring collapsed, by which the pitch of the string was retained and the tuning consequently preserved. It was never adopted to any great extent, but had its admirers: a want of firmness in the tone was perhaps its greatest defect. Mr. Riley's plan for *transposition* was simply a double set of keys, one sliding under the other, by which music might be played from the same scale a note or notes *higher* or *lower*. It was purchased by Messrs. Broadwood, and is now laid aside. It never was calculated to be of service to the practice of music; neither did it introduce any new or valuable idea to the mechanic. Mr. Mott's *sostinente* was an application of a cylinder and silk loops to an upright piano-forte. The loops were attached to the strings, and the cylinder, which was moved by the foot, as it were *bowed* them, and the tones came forth somewhat like the tones of the seraphine. Under Mr. Mott's fingers, this instrument was capable of most pleasing effects, but without such aid, we never esteemed the invention. Mr. Kirkman's *octave string*, was applied as the third string of a grand piano; this string was an octave higher in pitch than the other two, and was somewhat in effect like two diapasons and a principal in an organ, but not so marked in character. It pleased for a time, but is now no more thought of. Mr. Trotter's *alternated key-board* was completed about fifteen years ago. Its peculiarity was that of alternating the keys: thus the octave came within seven white keys; the black keys too were passed *under* the *white*, and finished in front of them *below* with *broad heads;* by which arrangement a black key could be taken by either the *thumb* or the *finger*, at the option of the performer. This instrument was called by Mr. Trotter a *transposing piano-forte;* and he went so far as to promise a *new notation* for it, which notation he seemed to think would do away with the present altogether. That he did not live to perform his promise we much regret; for certainly double sharps and double flats, with all their accidentals, are anything but agreeable to those who cannot devote their whole lives to the study of music.

There is one other point to which we would draw attention, and that is what is called the *bracing* of piano-fortes. Our inquiries have led us to this subject, and we find that in flat instruments, especially grands, there is a difficulty in giving strength to the bracing. Some makers are for iron, and some for wood; but wood, it seems, is inconvenient, and iron is therefore mostly adopted. That strength is important, and very important, is quite clear, when we know that the strings of a grand piano-forte pull equal to a weight of *six tons*. Iron as a substance, doubtless, has the greater strength, but may not wood be so applied as to be strong enough? That wood is more sonorous than iron, there has never, we believe, been a question, and we will yet hope that sooner or later it will be allowed to be a better material. The ingenuity and capital now employed in this interesting branch of manufacture give us some promise that the day is not far distant when a more uniform and successful practice will be adopted in the construction of the piano-forte. If this can be accomplished, what may not be expected from future Hummels and Thalbergs?

PIAPEC, the name of a bird from Senegal, forming the genus *Ptilostomus* of Swainson, intimately related, according to M. Temminck, to his *Corvus gymnocephalus*. This form is placed by Mr. Swainson among his subfamily *Glaucopinæ*, *Wattle* or *Rasorial* crows, in his family *Corvidæ*.

PIASTRE. [MONEY.]

PIAZZA, a term adopted in its original form from the Italian, but with a great change of its meaning; for while in that language it signifies merely an open place, it is employed by us to denote a covered ambulatory, whether formed by columns or arches, in the lower part of a building, such cloistered walks being very common in the *piazze* or public squares of Italian cities, as that of St. Mark's at Venice, &c. Yet, although we have borrowed the term, it has been rather as a distinct name applied in a few particular cases than as a general denomination; for excepting Inigo Jones's arcade, on the north and part of the east side of Covent Garden, which is expressly called the 'Piazza,' we have scarcely another instance in London, such projecting colonnades as those of the Opera House and the Quadrant being different in architectural character, as may instantly be perceived by comparing the last-mentioned with the small piazza beneath the County Fire-Office adjoining to the Quadrant. Though for a different reason, such an arrangement has quite as much to recommend it in this country as in Italy itself; at least for principal thoroughfares and trading streets; because if not required as a protection against the sun, it is desirable as affording dry and sheltered walks and clean pavement in all weathers in those parts of the town where, owing to the crowd and constant traffic, rain and dirt are most annoying to foot-passengers. Accordingly, in his plans for rebuilding the City after the Great Fire, Sir C. Wren proposed to carry piazzas beneath the fronts of the houses of the principal streets; but prejudice or something else determined otherwise; nor has such a highly convenient mode of building, as regards public accommodation, been since adopted in any of the improvements and new streets formed in the vicinity of New London Bridge.

PIAZZA, Town of. [SICILY.]

PIAZZI, JOSEPH, was born at Ponté in the Valteline (Switzerland), July 16, 1746. His education appears to have commenced at Milan, where he assumed the habit of the Théatins, and became an inmate of the convent of St. Anthony. Here and at Turin he studied the classics and mathematics under Tiraboschi and Beccaria, and at Rome under Lesueur and Jacquier, the editors of the Jesuits' edition of the 'Principia.' He began to teach philosophy at Genoa; but having expressed himself too openly on certain theological points, he was threatened with the persecution of the Dominicans, from which he escaped by accepting the professorship of mathematics in the new university of Malta, conferred upon him by the grand-master Pinto. Upon his return to Italy, he became professor of philosophy and mathematics in the College of the Nobles at Ravenna; but here again his religious opinions made him many enemies. Soon after the publication of two philosophical theses, which were deemed 'too bold for so young a divine,' he found it expedient to retire, first to Cremona, and thence to Rome, where he was for some time reader of dogmatic theology at S. André della Valle. In 1780, at the recommendation of Jacquier, he was appointed professor of the higher mathematics in the Academy of Palermo, where, with the co-operation of the viceroy, he founded an astronomical observatory. In 1787 he visited Paris, where he made the acquaintance of Lalande, Jeaurat, Pingré, Delambre, and Bailly; also of John Cassini, Mechain, and Legendre, who were at that time occupied in determining the difference of longitude between the observatories of Paris and Greenwich. He next visited England, where he became intimate with Maskelyne, Herschel, Vince, and more particularly with Ramsden, to whom he confided the construction of the instruments for his new observatory. Much of his time during his stay in England was passed at the observatory of Greenwich. Here, with Dr. Maskelyne, he observed the solar eclipse of June 3, 1788; and the year following he communicated a paper to the Royal Society (*Phil. Trans.*, vol. 79, p. 55), containing the observations of that eclipse by twelve other astronomers, and the consequences thence deduced by himself relative to the longitudes of the several observatories. At that time the longitude of the Dublin observatory was taken at 24^{m} 58^{s}; Piazzi gives 25^{m} $13{\cdot}4^{s}$, and expresses his confidence that this is within two seconds of the truth: the longitude now given in the 'Nautical Almanac' is 25^{m} 22^{s}. This paper is understood to be his earliest production as an astronomer. Having after much importunity obtained the completion of his instruments, he returned with them to Sicily in the latter part of the year 1789, and very soon after became one of the most active and accurate of modern observers. The observatory of Palermo was at that time the most southern in Europe, that at Malta having been recently destroyed by fire. In the course of the first ten years he determined the positions of no less than 6748 stars. His first catalogue was published in 1803, under the title of 'Stellarum Inerrantium Positiones,' which was deservedly honoured by the Academy of Sciences of Paris, and acquired for its author the esteem and admiration of astronomers. It was while thus occupied that he discovered, January 1, 1801, the first of the four planets now known to be situated between the orbits of Mars and Jupiter, and to which he gave the name of Ceres Ferdinandea, out of compliment to his patron the king of Naples. [CERES.] Ferdinand would have commemorated the event by circulating among the astronomers of Europe a gold medal bearing the effigy of Piazzi; but the latter suggested that the money would be more usefully applied in the purchase of an equatorial, of which the observatory was in need.

In 1817 he was called to Naples to put into activity the new observatory erected by Murat on the heights of Capo di Monte. He was succeeded in the observatory of Palermo by M. Cacciatore, to whom he had previously confided the difficult task of re-examining Maskelyne's thirty-six principal stars. The observations of Cacciatore, which were extended to 120 stars, form the basis of Piazzi's second Catalogue of 7646 stars, published in 1814. Speaking of this catalogue, the council of the London Astronomical Society remark, in their seventh annual Report, that 'it exceeds everything of the kind which preceded it, and shows more powerfully than words can express what may be effected by the talents and assiduity of one individual.' Piazzi was a member of the principal scientific societies of Italy, France, and Germany. Of the Royal Society of London he was elected a fellow in 1804, at the same time with Baron Zach and Professor Gauss. He died at Naples, July 22, 1826. His library and instruments he bequeathed to the observatory of Palermo, and a liberal annuity in perpetuity, to be appropriated in succession to the education and maintenance of young men who evince a marked partiality for astronomical science.

The preceding notice is chiefly drawn from an article in the 'Bulletin des Sciences' for 1826, drawn up by De Angelis under the eye of the Baron Zach. A more detailed account of Piazzi's life and labours has long been expected from the pen of his friend Colonel Visconti, the present director of the geographical engineers at Naples. The published works of Piazzi mentioned in different numbers of the 'Bulletin des Sciences' are collected and appended to a translation of the above article in Brewster's 'Journal' for 1827 (vol. vi., p. 193). They are as under:—

1, 'Discourse on Astronomy,' Paler., 1790.

2, 'Description of the Observatory of Palermo,' in 9 books, of which four were published in 1792 and five in 1794.

3, 'On the Discovery of the Planet Ceres,' Palermo, 1802.

4, 'Observations on the Obliquity of the Ecliptic,' 1804. (*Mem. Soc. Italiana*, tom. xi.)

5, 'On the Precession of the Equinoxes,' 1804. (*Ephem. de Milan.*)

6, 'On the Parallax of some of the Fixed Stars.' (*Mem. Soc. Italiana*, xii.)

7, 'On the Measure of the Tropical Year.' (*Id.*, tome xiii.)

8, 'On the Proper Motion of the Fixed Stars.' (*Mem. de l'Inst. Nat. Ital.*, tome i.)

9, 'The Metrical System for Sicily,' 1812.

10, 'Lessons in Astronomy,' 1817.

11, 'On the Observed and Calculated Solstices.' (*Mem. de l'Inst. de Milan*, tome ii.)

12, 'On the Italian and European Clock.' (*Giorn. de Scienze par la Sicilia*, Aug., 1824.)

13, 'On the Progress of Astronomy.' (*Giorn. de Soc. Lett. et Arti par la Sicilia*, April, 1824.)

14, 'Description of the Meridian of the Cathedral of Palermo, established by Piazzi in 1798,' by M. Cacciatore. (*Id.*, August, 1824.)

PIBROCH, in Scottish music, the march or battle-tune of the Highland clans.

PICA. [CORVIDÆ, vol. viii., p. 68; MAGPIE.]

PICAMAR, a peculiar compound obtained by Reichenbach from wood-tar.

Its properties are—that it is nearly colourless, limpid, and transparent; it has the consistence of a thickish oil; to the touch it is greasy; its smell is not very strong or disagreeable, but it is peculiar; the taste of picamar (*in pice amarum*) is intolerably bitter, and at first burning, but afterwards cooling, like peppermint. Its specific gravity is about 1·10. At common temperatures oxygen has no sensible action on picamar; even when it has been long exposed to the air, it becomes only slightly yellowish, but when boiled in contact with it, it becomes gradually brown; its boiling point is about 545°. In water, whether cold or hot, it dissolves sparingly, and the solution has no effect either on litmus or turmeric paper.

It dissolves in acetic acid, and the bitterness of pyroligneous acid is derived from its presence. Alcohol, æther, pyroxylic spirit, and creosote dissolve it readily. It dissolves sulphur, phosphorus, and selenium, and, when hot, caoutchouc also, but this is deposited as it cools. In cold sulphuric acid it dissolves without decomposition, but this takes place when they are heated together. By nitric acid it is decomposed, and a reddish brown mass is formed, but without any oxalic acid.

Picamar combines with ammonia, soda, lime, and barytes, and with potash it forms a crystalline compound which is nearly insoluble in alcohol; but when it is diluted and heated, it takes up a large quantity of this compound, which on cooling separates in white brilliant crystals.

It has not been analyzed, and has not as yet been applied to any useful purpose; but it has been suggested that it may be usefully employed in preventing steel instruments from rusting.

PICARD, JEAN, was born 21st July, 1620, at La Flèche in the present department of the Sarthe, and became priest and prior of Rille in the same department. Scarcely anything is known of his early history. Even the names of his parents appear to have been forgotten, as they are not mentioned by Lalande, who visited his birth-place. Pezenas, in his 'Critical History of the Discovery of the Longitude,' referred to by Delambre, speaks of one Picard, a gardener of the duke of Crequi, whom the astronomer Le Valois instructed so successfully in the use of astronomical instruments, that he became one of the most celebrated observers of his age. As the subject of this article is the only Picard who is known to have acquired any celebrity as an astronomical observer, it may be conjectured that he was the humble individual here alluded to. The earliest event with which his name is associated, and of which the date is recorded, is the solar eclipse of 25th August, 1645, which he observed with the astronomer Gassendi, whom he succeeded, in 1655, as professor of astronomy in the College Royal of France. He was one of the eight individuals selected by Colbert, in 1666, to originate the Academy of Sciences. The following year he made his first application of the telescope to the measurement of angles; which alone, observes Delambre, would entitle him to the esteem and remembrance of astronomers. Prior to this, plain sights only had been used, with which not only are distant objects frequently altogether invisible, but of those which can be seen the outline is seldom distinctly defined, while in some cases, as in the fixed stars, they have an apparent magnitude which they do not really possess. According to Lahire however the merit of this great improvement (which was eagerly adopted by every astronomer of note, Hevelius excepted) is divided between Picard and Auzout, who were in partnership, though, from Picard's description of his invention, in his work entitled 'Figure de la Terre,' it would appear to be exclusively due to himself. Soon after this he introduced an entirely new system of astronomical observation, wherein the pendulum, then recently invented by Huyghens, is first brought into use in determining the right ascension of the stars by noting the instant of their passage across the meridian. [TRANSIT INSTRUMENT.] This method, observes Delambre, which is adhered to at the present day, 'insures to those two authors, Huyghens and Picard, an incontestible superiority over all the astronomers of the time without a single exception.' In the memoir wherein these views are more fully developed, and which he read before the Academy of Sciences, in April, 1670, he urges the necessity of forming more correct tables of the sun and fixed stars, as also tables of refraction, which he regarded as the chief foundation of all sound practical astronomy. For this purpose he solicited the erection of a mural quadrant, which after many years of needless delay was finally adjusted in the plane of the meridian, not however till Picard was upon his death-bed. In 1671, with a view to give astronomers greater confidence in employing the observations of Tycho Brahé, Picard visited the island of Hoëne in order to determine the position of Uraniberg. Scarcely a vestige of the observatory remained; sufficient however to enable him to detect an error of one minute in the latitude and several minutes in the longitude, as given by Tycho, which confirmed the suspicions previously entertained by astronomers. While absent on this occasion he met with Röemer, then a young man, with whose mathematical talents he was so well pleased that he brought him to Paris and introduced him to the academy. The observatory of Paris, the plan of which had been furnished by Picard, was completed in 1671, when it was immediately occupied by Dominic Cassini, who, at Picard's recommendation, had been invited by Colbert to take up his residence in France. It was not till two years later that inferior accommodation within the same building was allotted to Picard. 'He saw,' says Delambre, 'all his projects neglected or their execution deferred; all expenditure and encouragement lavished upon objects of less utility, though to the eye of the vulgar of a more brilliant character, such as the rotation of the three planets, and the four new satellites of Saturn; while telescopes of great cost were imported from Italy to verify these discoveries, which, though certainly very curious, were and always will be useless.' The astronomical ephemeris entitled 'La Connaissance des Temps,' originated with Picard in 1679, and was continued by him till his death. The same year he was nominated with Lahire, by the king, to conduct certain surveys along the coast of Gascony, the result of which sufficiently indicated the necessity of constructing an entirely new map of the country. For this purpose he proposed the extension of the arc of the meridian passing through the Paris observatory as far as the extremities of the kingdom: a proposal which has since been carried into effect. As an observer, he was no less industrious and accurate than, as a philosopher, he was enlightened. His observations from 1666 to 1682, collected and published by Lemonnier in 1741, under the title of 'Histoire Céleste,' are a sufficient proof of his activity; while his perseverance for ten years in observing the minute variations which, from causes then unknown, are continually taking place in the altitude of the polar star, is equally conclusive as to his zeal and the perfection which astronomical observation attained in his hand.

What Picard is however now chiefly remembered for, is his measurement of an arc of the meridian of Paris between Amiens and Malvoisine. This was begun in 1669, and forms the subject of his work entitled 'Mésure de la Terre,' Paris, 1671, a large folio of 30 pages. The base extended along a paved road from Villejuive to Juvisy; it was twice measured, the results being $5662\frac{5}{6}$ and $5663\frac{1}{6}$ toises, the mean of which was taken. The difference between the latitudes of Amiens and Malvoisine he found to be 1° 22′ 55″, and the length of the intermediate arc 78,850 toises; whence it followed that the length of one degree between those latitudes was 57,057. The toise employed was that of Chastelet. 'Lest,' says Picard, 'this toise should share the fate of those employed in former surveys, of which only the name remains (it has since been lost), we will connect it with a measure which, being taken from nature herself, *must be invariable and universal.*' He then states that he determined with great care the length of the pendulum vibrating seconds (which he supposed was constant for all latitudes), and which at Paris he found to be 440·5 lignes, according to the toise of Chastelet. (*Mésure de la Terre*, p. 4.) The most accurate determinations which have since been made do not differ from this result by so much as the $\frac{6}{100}$ of a ligne. (Francœur, *Géomorphie*, p. 256.) At the date of this survey the law of refraction was imperfectly known, and its effects were neglected. The effects arising from what have since been termed aberration and nutation [ABERRATION; PRECESSION AND NUTATION] had been felt, but astronomers then, and for more than half a century afterwards, knew not how the requisite corrections should be applied. These were therefore sources of error which vitiated the observations of Picard in common with those of all other astronomers of that time; and in addition an error of six toises was committed in the measurement of the base. The whole of the operations have since been repeated by Lemonnier (*Degré du Meridien*, Paris, 8vo., 1740) and Lacaille, and still more recently by Delambre. The final result gives 57,074 toises for the length of the degree, which differs from Picard's by 17 toises (35·6 English feet); and, thus rectified, this measurement is one of those on which the greatest reliance is now placed. The care with which the whole of Picard's operations were conducted, and the superiority of his instruments and methods over those employed in any previous survey, naturally produced considerable confidence in his result. Astronomers would not indeed have been justified had they regarded the results of former surveys in any other light than rough approximations which enabled them to assign the limits within which the true dimensions of the earth would one day be found, but which were useless in determining what its dimensions and figure really were. Newton, in 1666, failed to establish the truth of his theory of gravitation by employing an erroneous measure of the earth's radius, and did not resume its consideration till he heard of Picard's survey, by which it was confirmed. Norwood's measurement of the arc of the meridian between London and York, which took place in 1633, gave results which have since been shown to be correct, and were doubtless known to Newton. But his measurement differed too considerably from those which preceded it to be admitted on the strength of the imperfect apparatus employed by him. Norwood's measure is called by Delambre a great piece of good fortune. [Norwood.]

Picard died at Paris, 12th July, 1682 (Delambre): according to other authorities, his death took place in 1683 or 1684. Besides the works already mentioned, the following are inserted in the 'Memoirs' of the Academy of Sciences. The numbers refer to the volume:—

vi. De la Pratique des Grands Cadrans par le Calcul: De Mensuris; De Mensurâ Liquidorum et Aridorum; De Proportione Aquarum Effluentium; Fragments on Dioptrics; Treatise on Levelling. All but the last are in the 'Divers Ouvrages,' &c., fol., Paris, 1693.

vii. Measurement of the Earth; Astronomical Observations made in Denmark; Astronomical Observations made in various parts of France (4 papers).

x. Immersion and Emersion of Jupiter's Satellites observed at Paris in 1668; Observation of the Lunar Eclipses of 7th July, 1675, and 11th January, 1676, by Cassini, Picard, and Roemer (2 papers); Experiments relative to the Phenomenon observed in the Vacuum of the Barometer; Occultation of Saturn by the Moon, observed by Cassini, Picard, Roemer, and De La Hire.

(Delambre, *Astronomie Moderne*, and *Biographie Universelle*; Lalande, *Biographie Astronomique*; Condorcet, *Eloge de Picard*; Fontenelle's *Eloge de Picard*; Montucla, *Hist. des Mathématiques*, &c.)

PICARD, LOUIS BENOIT, member of the French academy, and one of the most talented and successful dramatists of his age, was born at Paris, in 1769. His first production for the stage (in writing for which he was guided at the outset by the advice and instructions of his friend Andrieux, the author of 'Les Etourdis,' and several other popular pieces) was 'Le Badinage Dangereux,' which was followed by a very long succession of comedies, displaying novelty in their subjects, faithful and well hit off portraitures of contemporary manners, playfulness of dialogue, and clever traits of satire; to such degree indeed that by some he has been styled the Molière of his day. Not only were his productions eminently popular at home, but many of them were either translated or remodelled by Iffland, Hell, and other German writers. Among his pieces in verse, 'Mediocre et Rampant,' 'Le Mari Ambitieux,' and 'Les Amis de Collège,' are generally considered his best; while the 'Contrat d'Union,' 'La Petite Ville,' and 'Les Marionettes' are regarded as his master-pieces among those in prose. Besides their literary merits and the strong comic talent they evince, it is not the least recommendation of Picard's dramas that they have for the most part a useful moral aim and tendency. Numerous as are his productions of this class, they by no means constitute the whole of his literary compositions, for he likewise wrote the 'Gil Blas de la Révolution,' and several other novels which obtained considerable vogue. Among these, 'L'Honnête Homme' has been translated into English under the title of 'The Novice, or Man of Integrity;' and although exaggerated in the chief character, it contains several striking and well-drawn scenes replete with latent satire. In addition to these various labours with his pen, Picard was at one time a performer at the Théâtre Louvois, and from 1801 director of that theatre. He was afterwards successively manager of the Opera and the Odeon theatre, which latter post he continued to hold when that house was rebuilt after being burnt down in March, 1818. He died December 31st, 1828.

PICARDIE (LA), a maritime province of France, constituting one of the military governments into which, before the Revolution, that kingdom was divided. It was bounded on the north-east by Artois and Flandre Française (French Flanders), on the east by Champagne, on the south by the Île de France, on the south-west by Normandie, and on the west and north-west by La Manche, or the English Channel. Its form was very irregular. The part south of the river Authie had its chief extension from west to east, about 145 miles from the mouth of the little river Bresle (which divided Picardie from Normandie) to the neighbourhood of Rocroy in Champagne; but the breadth of this portion from north to south was in no part greater than 60 miles, and generally was much less. A narrow strip of the province projected from this southern part along the coast, about 50 miles northward from the Authie, but not having in any part a much greater extension inland from west to east than 20 miles.

The province above described was sometimes distinguished as Picardie Septentrionale (Northern Picardie), in order to distinguish it from the districts of Beauvaisis, Valois, Soissonnais, Laonnais, and Noyonnais, to which, though included in the military government of the Ile de France, the name of Picardie Méridionale was sometimes given. The etymology of the name Picardie, and the time when it first came into use, are uncertain: there is no evidence that it was employed before the twelfth or perhaps the thirteenth century. This province had no feudal unity, and therefore no history to be recorded here; a brief notice of the changes to which it has been subject will be found under the departments into which it is now divided. [Pas de Calais; Somme.]

Picardie was divided into Haute and Basse, Upper and Lower. Haute or Upper Picardie (in which Picardie Méridionale was included), comprehended the districts of (1) Amiénais, chief town Amiens (population 45,001); (2) Santerre, chief town Péronne (population 3802); (3) Vermandais, chief town St. Quentin (population 17,686); and (4) Thiérache, chief town Guise (population 3072). The districts of Picardie Méridionale are mentioned above. Amiénais, Vermandais, Beauvaisis, and Soissonnais preserve respectively the designations of the Belgic nations by which they were inhabited; the Ambiani, the Veromandui, the Bellovaci, and the Suessiones. Basse or Lower Picardie comprehended the three districts of Le Calaisis, Le Boulonnais, and the county of Ponthieu, of which the capitals were respectively Calais (population 10,437), Boulogne (population 20,856), and Abbeville (population 19,162); Le Calaisis was sometimes designated Le Pays Reconquis on account of its recovery (A.D. 1558) from the English, by whom it had been long held. Le Boulonnais was sometimes divided into Haut and Bas, the former having Etaples for its chief town, the latter Boulogne. Le Ponthieu was subdivided into Ponthieu, properly so called, chief town Abbeville; the county of Montreuil, chief town Montreuil (population 4083); the district of Marquenterre, chief town Quend-le-Jeune; and the district of Vimeux, chief town St. Valery-sur-Somme (population 3265) A small part of the eastern extremity of Picardie is included in the department of Aisne.

The population given above is that of the communes, from the census of 1831.

PICCI'NI, NICOLO, was born at Bari in the Neapolitan dominions, in 1728. His father, a musician, intended him for the church, but the predilection of the son for his parent's profession was too strong to be overcome, and at the age of fourteen he was entered at the Conservatorio *Santo Onofrio*, where he completed his studies under Leo and Durante. The first marked proof of his genius for composition was evinced in his serious opera *Zenobia*, produced at the theatre *San Carlo* in 1756. This led to his being invited to Rome, where he brought out *Alessandro nell' Indie*, which was eminently successful. Four years after appeared, in the same city, his comic opera, *La buona Figliuola*, the drama by Goldoni, founded on Richardson's *Pamela*, which was, and ever will be, considered as Piccini's masterpiece, and be admired for the originality, the beauty, and the appropriateness of its airs, as well as for the judicious manner in which the accompaniments are written, simple as they are, compared with those of a later age. It saved the manager of the *Teatro delle Dame* at Rome from ruin, and excited a degree of enthusiasm amounting to extravagance: dresses, wines, nay buildings, took the name of the principal character in the piece, *La Cecchina;* and during several years the fireworks displayed on the festival of the patron saint of the city exhibited scenes from the opera, which was the favourite of all ranks. This was given in London in 1766, with an effect but little less than it had produced at Rome. Next year saw his *Olimpiade,* in which is the aria 'Se circa, se dice,' a chef-d'œuvre. He now was applied to from all quarters in Italy to furnish the various theatres with operas, and he composed many, most of which were very successful, though now forgotten, a circumstance which ought to excite no surprise, as we are informed by M. Ginguené that in the short space of a few years he had produced one hundred and thirty-four operas, besides a vast number of masses, cantatas, and detached pieces.

Piccini having received a pressing invitation to Paris, arrived there in 1776, and prepared himself to compose for the *Académie Royale de Musique.* His first difficulty was an utter ignorance of the French language; but Marmontel, by becoming his instructor, soon removed this impediment. He next had to contend against national prejudices, and also very formidable rivals, namely Gluck, and afterwards Sacchini. For some account of the musical feuds in Paris to which his visit gave rise, we must refer to our notice of GLUCK. His *Roland*—a drama by Quinault—by which he introduced himself to a Parisian audience, met with every possible success, and though it led to a furious war among the connoisseurs as well as amateurs of all degrees, the composer was, by its means, firmly established in the French capital, and chosen as director of *L'Ecole de Chant,* having previously been appointed singing-master to the queen.

The Revolution drove Piccini back to Naples, after losing nearly all his property. He was at first received with smiles by his own sovereign, but having carried with him to his native country political opinions not likely to be pleasing to the ears of an absolute monarch, and which he had the imprudence to pour into them, he was disgraced, proscribed, and placed under the surveillance of the police. In 1798 he contrived to return to Paris, where his friends obtained for him a pension of 5000 francs, besides a gratuity of 2400 more from the society *Des Encouragemens Littéraires,* with the addition of apartments in the Hôtel d'Angivillier. His various anxieties however brought on a paralytic affection, from which he recovered, and was received with kindness by the First Consul, who appointed him inspector of the *Conservatoire de Musique.* But shortly after, oppressed by domestic afflictions, he experienced a return of his former attack, under which he finally sunk in 1800, and was interred at Passy, where a handsome tomb is erected to his memory.

PICCOLOMINI FAMILY. [PIUS II.]

PICCOLO'MINI, ALEXANDER, born at Siena in 1508, died 1578. He was titular archbishop of Patras, and coadjutor of the archbishop of his native place. No events of his life are particularly worth recording, but the wide extent of his writings, and the esteem in which they were held by his contemporaries and immediate followers, make his name remarkable. He was moreover of an original turn, and his writings are almost all in Italian, so that he is among the earliest of those who endeavoured to raise the character of vernacular literature, by treating all branches of knowledge in modern tongues. His commentaries on Aristotle were prized for their good sense and for their abandonment of most of the scholasticisms which have since procured for that philosophy an undeservedly bad reputation. He advocated (in 1578) the reformation of the Calendar, which was afterwards adopted. In his book on the fixed stars and the sphere, he adopts the mode of designating the stars by letters; a small matter, but one which makes the greater part of the immortality of Bayer, and to which the diagrams of Piccolomini establish his prior claim. His works are of a most miscellaneous character—astronomy, physics, comedies, sonnets, morals, divinity, and commentaries on Aristotle. De Thou speaks in strong terms of the rare union of diversity and depth which his acquirements presented.

PICE'NUM. [MARCA D'ANCONA.]

PICHEGRU, CHARLES, a general of the French republic, was born of humble parents, in 1761, at Arbois in Franche-Comté. He studied at the college of Brienne, enlisted as a common soldier, and accompanied his regiment to America. On his return he was promoted to be serjeant-major. He embraced the principles of the revolution, and in 1793 commanded the army of the Rhine. In the following year (1794) he succeeded General Hoche in the command of the army of the North, which was in a state of great disorder. M. Thiers says of him—'He possessed spirit and resolution, but his military genius did not rise above mediocrity.' Be that as it may, he restored order and discipline in the army, and when the French went into winter-quarters, they were masters of the whole country to the line of the river Wahl, excepting Nimeguen, the isle of Bommel, and Breda. The winter proved exceedingly severe, and as soon as the ice was sufficiently strong to bear artillery, Pichegru made a simultaneous and completely successful attack on the above places, and crossed the Wahl in January, 1795. The English were obliged to embark, the prince of Orange abandoned his army, and recommending the states to make no more resistance, fled to England, and nothing remained for the French but to take possession of the entire country. The plan of the early part of the campaign is said to have been traced out by Carnot, but Pichegru deserves the reputation that he gained by the energy and foresight he displayed in this winter campaign. On his return to Paris, he was appointed general of the army of Paris during the insurrection of the fauxbourgs in April, 1795, and, by the confidence with which his presence inspired the troops, he mainly contributed to restore tranquillity. He then joined the army of the Rhine, where he entered into correspondence with the prince of Condé, with a view of restoring the Bourbons to the throne. His treason being shortly suspected, he was superseded in the command of the army of the Rhine by Moreau, in 1796. The embassy to Sweden was offered to him and declined, and he retired to Jura, for which department he was elected in 1797. Thiers says 'he had too much tact and was too prudent to conceive any project of counter-revolution at this time; but he received the royalists' money, and gave in return plenty of promises.' He next became president of the Council of Five Hundred, and being detected in a conspiracy to overthrow the republican party, he was arrested September 4, 1797, sent to the Temple, and, with Barthelemy, Willot, and several more, immediately transported to Cayenne. After eight months he made his escape to England, where he was well received as a partisan of the Bourbons. In 1804, Pichegru and Georges Cadoudal were employed with several of the Vendean leaders to organise a plot to overthrow the government of the First Consul. Being detected by the police, Pichegru was arrested at Paris on the 17th February, and sent to the Temple. While a process was being commenced against him, he was found, on the morning of the 6th April, 1804, strangled. An attempt was made to affix the stigma of his murder on Bonaparte, but there do not seem to be grounds sufficient to establish this charge. (Thiers, *Hist. de la Revolution; Biog. Universelle.*)

PI'CIDÆ. [WOODPECKERS.]

PICO. [AZORES.]

PICO, GIOVANNI DELLA MIRA'NDOLA, born in 1463, was the son of Giovanni Francesco Pico, count and sovereign of the little state of Mirandola and Concordia, which now forms part of the Modenese territory. [MODENA, DUCHY OF.] He was a precocious youth, and gifted with a prodigious memory; he studied almost every branch of learning which was then taught, philosophy, law, philology, general literature, and poetry. He learned Latin, Greek, Hebrew, Chaldaic, and Arabic. With regard to philosophy, he followed the Platonic, or rather the Neo-Platonic, or Alexandrine school. He travelled through France and Italy, and sustained public scholastic disputations in several universities. He was pleased to argue on both sides of a question, and he thus acquired a wonderful reputation for learning. When twenty-three years of age he went to Rome, where he drew up nine hundred propositions on all kinds of subjects, logic, ethics, physics, metaphysics, theology, mathematics, astrology, and the cabbala, inviting all the learned of Europe to argue with him upon each and all of them. This challenge was accepted in some instances, in which he is said to have come off victorious. But this display of erudition was not without danger, especially in that age. Out of the 900 propositions, 13 were picked out by officious persons which savoured of heresy, or incredulity, or something of the kind, and were denounced to Pope Innocent VIII., who ordered a strict inquiry upon so grave a subject. Pico wrote his defence, which was drawn up with great modesty, and in which he professed his submissive orthodoxy. In conclusion the pope condemned the propositions, but acquitted the author of any heretical intention. One of these propositions referred to the eternity of punishments in the next world. Pico maintained that sin, being finite, could not be subject to an infinite penalty, but he afterwards modified his proposition by saying that ‘sin includes two offences, one the gratification of a passion, which is finite, and another, the contempt of the grace of God and eternal happiness, which are infinite, and therefore may on the second account deserve an infinite punishment.’

At last Pico chose Florence for his residence, being attracted thither by the renown of Lorenzo de' Medici and his friends. (Machiavelli, *Stor. Fiorent.*, vi.) He there disputed and wrote upon the Platonic philosophy, which he strove to reconcile with the scriptures. He also wrote a work against astrology, in 12 books, which is perhaps the best of his writings, and likewise a dissertation on antient mythology, and a commentary on the book of Genesis. His works have long since been forgotten. He died at Florence, in November, 1494, at the age of thirty-two, on the very day that Charles VIII. of France entered that city. His nephew Gian Francesco Pico wrote his biography.

PICROLITE, a mineral which occurs massive, with a thin fibrous radiated structure. Colour leek or yellowish green. Fracture splintery. Hardness 3·5 to 4. Opaque, or translucent on the edges. Lustre slight, but somewhat pearly. Before the blowpipe it colours borax green, the colour disappearing on cooling. This mineral is found at Taberg and Nordmorken in Sweden, traversing beds of magnetic iron-ore. It is stated also to have occurred at Reichenstein in Silesia. Analysis by Klaproth:

Silica	40·04
Carbonic acid . . .	4·70
Magnesia . . .	38·80
Protoxide of iron . .	8·28
Water	9·08
	100·90

PICROSMINE, a mineral which occurs crystallized and also massive.

Primary form a right rhombic prism. Fracture indistinct, uneven. Hardness 2·5 to 3. Nearly opaque. Lustre dull; vitreous. Colour greenish white, or sometimes dark green or even blackish. Streak white and dull. Specific gravity 2·58 to 2·66.

Before the blowpipe it gives out water, but does not melt; it becomes black, and then white and opaque, and acquires a hardness = 5.

Massive Varieties.—Structure thin, fibrous; fracture splintery; granular to compact.

Found in the iron-mine of Englesburg near Presnitz in Bohemia. According to Magnus, it consists of

Silica	54·88
Magnesia . . .	33·34
Protoxide of iron . .	1·39
Protoxide of manganese .	0·42
Water	7·30
	97·33

PICROTOXIN, the principle to which *cocculus indicus* owes its deleterious properties. It is extracted by the action of water and alcohol, and eventually crystallized.

The properties of picrotoxin are, that its crystals are usually acicular, but sometimes filamentous, in plates and in hard granular crystals. It is intensely bitter, is soluble in 150 times its weight of cold water, and 25 times when boiling. Alcohol of specific gravity 0·810 dissolves one-third of its weight, and sulphuric æther of the specific gravity of 0·7 takes up two-fifths of its weight; in oils it does not dissolve.

It does not act upon test papers, thus evincing the properties neither of an acid nor an alkali, though it was once supposed to possess those of the latter. The acids do not appear to increase its solubility in water, but the alkaline bodies do possess this property, to a considerable extent, and it is precipitated from them by the addition of acids.

According to Pelletier and Couerbe, it consists of—

Hydrogen . .	6·00
Carbon . . .	60·91
Oxygen . . .	33·09
	100·

PICTOR, FABIUS. [Fabius Pictor.]

PICTS, an antient people of North Britain, whose origin and history are singularly obscure, and have furnished matter for endless speculation and controversy. The name does not occur in the enumeration of the British tribes given by Ptolemy in the beginning of the second century; nor are the Picts noticed by his successors Dion Cassius and Herodian, the latter of whom wrote about A.D. 250, any more than they are by his predecessors Julius Cæsar and Tacitus. This has not prevented some writers from maintaining that the Picts were settled in Britain before Cæsar's invasion; that is, for instance, the opinion of Pinkerton; but it is certainly at least in the highest degree improbable that they should have been passed over by Ptolemy if they were here in his time. The earliest mention of them by any antient writer occurs in an oration addressed by the rhetorician Eumenius to the emperor Constantius Chlorus, on his return from his victory over the usurper Allectus, in the year 296. [Constantius I.] Eumenius there speaks of the Britanni in the time of Julius Cæsar (according to the best reading of the passage) as ‘Solis ... Pictis modo et Hibernis adsueti hostibus’—having been used only to the Picts and Irish as enemies. All however that we can infer from this expression is, that the name of the Picts was familiar to Eumenius at the end of the third century; it would be demanding far too much historic precision from a mere declaimer to assume on such authority that it was equally well known to Cæsar three hundred and fifty years before. The same Eumenius, in another panegyrical oration addressed to Constantine the Great, the son of Constantius, in 310, again mentions the Picts, and this time seems to use the word as the generic name for all the northern British tribes; ‘non dico Caledonum, aliorumque Pictorum, silvas et paludes,’ are his words. This expression has principally led the majority of inquirers to the conclusion that the Caledonii (or Caledones, as they are here called) were really the same people with the Picts. As Pinkerton, who himself adopts this opinion, observes, ‘Buchanan, Camden, Lloyd, Innes, Whitaker, the Macphersons, O'Conor, D'Anville, though differing widely in other points, all join here.’ But this again appears to be attributing to a rhetorical sentence-maker a great deal too much weight as an historic authority. Besides, the words Eumenius uses would imply, not that the Picts were the same with the Caledonians, but that the Caledonians were in fact only a tribe of Picts—although both Tacitus and Ptolemy, who were well acquainted with the former, appear to have been entirely ignorant of the existence of the latter. In truth, all that can be safely deduced from this passage of Eumenius is merely that the Caledonians and Picts were then the most distinguished among the barbarous tribes inhabiting the woods and marshes of North Britain.

After the time of Eumenius we have frequent mention of the Picts in the Roman writers. Ammianus Marcellinus, under the year 360, speaks of the invasion of the borders of the Roman province in Britain by those wild nations the Scots and Picts—‘Scotorum Pictorumque, gentium ferarum.’ Again, in 364, he enumerates the ‘Picti, Saxonesque, et Scotti, et Attacotti,’ as harassing the Britanni with incessant attacks. We may just observe that the Scoti or Scotti mentioned in these two passages were in all probability not yet inhabitants of any part of Britain any more than were the Saxones. But the most important passage in Marcellinus relating to the Picts, although it refers to another probably still more important, which is unfortunately lost, occurs in his annals of the year 368, where he says that, in relating the actions of the emperor Constans (A.D. 337-350), he had already described as well as he could the situation of Britain, and that therefore it is necessary for him only to observe now, that at that time ‘Picti, in duas gentes divisi, Dicaledonas et Vecturiones, itidemque Attacotti, bellicosa hominum natio, et Scotti per diversa vagantes, multa populabantur.’ It thus appears that about the middle of the fourth century the Picts were understood to be divided into two tribes, the Dicaledonæ, or Dicaledones, and the Vecturiones. These two names have however occasioned much perplexity. The Vecturiones, or Vecturones, indeed, are mentioned by Richard of Cirencester, whose work however is possibly nothing more than a modern forgery; but the name Dicaledones occurs nowhere but in this passage of Marcellinus. It has been conjectured that the true word was probably Deucaledones, and with this emendation an interpretation of both names has been given which is at least ingenious and plausible. 'The term *Caledonii*,' says a late writer, 'is evidently *Caoilldaoin*, men of the woods, modified by Roman pronunciation. The term *Deucaledones* is attended with no difficulty. *Duchaoilldaoin* signifies, in the Gaelic language, the real or genuine inhabitants of the woods. *Du*, pronounced short, signifies black, but pronounced long, signifies real, genuine; and in this acceptation the word is in common use: *Du Erinnach*, a genuine Irishman; *Du Albinnach*, a genuine Scotsman. The appellation of *Deucaledones* served to distinguish the inhabitants of the woody valleys of Albinn, or Scotland, from those of the cleared country on the east coast of Albinn, along its whole extent, to certain distances westward towards the mountains in the interior parts of the country. These last were denominated, according to Latin pronunciation, *Vecturiones;* but in the mouths of the Gael, or native inhabitants, the appellation was pronounced *Uachtarich*. . . . That a portion of the country was known in antient times by *Uachtar* is evinced by the name of the well-known range of hills called *Druim-Uachtar*, from which the country descends in every direction towards the inhabited regions on all sides of that mountainous range.' (Grant's *Origin of the Gael*, pp. 276, 277.) Although however Marcellinus thus appears, as well as Eumenius, to regard the Caledonians as only a tribe of the Picts, it is probable that this is a mistake, arising naturally enough merely from the ascendency in the country that had been acquired by the latter. The Vecturiones in all probability were the only true Picts; the Dicaledones were another race altogether.

It is very doubtful indeed in how far we are to understand the Roman writers as meaning at all the same people we now call the Picts by their term *Picti*. That term seems always to have been used by them in the sense simply of painted men, rather than as the name of any particular people. At least this notion, which we find Claudian indicating in his 'nec falso nomine Pictos' (*De Text. Cons. Honorii*), and in other passages, seems always to have been suggested to them by the name, and to have therefore induced them to apply it loosely to all the wild inhabitants of the north of Britain who were in the habit of painting their bodies, or rather among whom they supposed that practice to exist. If any one of the North British nations, more especially if any one distinguished above the rest, bore an appellation somewhat resembling this term *Picti*, the Romans, with their usual carelessness as to such matters, would readily enough employ *Picti* as their translation of the native name, and, even although the people particularly indicated in the first instance might be remarkable among their neighbours for their superior civilization and for *not* painting their bodies, would still retain in that application the popular sense of the epithet, and would soon come to extend it as far over other tribes, no matter how different in real character and origin, as that notion would seem to justify. We believe this to be the actual history of the use of the term Picti in the Roman ethnography of Britain.

That there was in early times a people settled in North Britain bearing a name of which the Latin *Picti* was intended as the representative, may be pronounced to be a fact only to be disputed by that sort of scepticism which is not less hostile to the investigation and establishment of historic truth than the weakest credulity. They are mentioned under the name of Picti not only by Eumenius, Marcellinus, Claudian, and other Roman writers, but by Gildas, Nennius, Bede, and Paul Warnfrid (Paulus Diaconus), all of whom lived while the Pictish kingdom still subsisted in the country now called Scotland; Bede even gives a history of the first settlement of the Picts in North Britain, which may be correct or not, or partly truth, partly fable, but which agrees in some remarkable points with the accounts both of the Irish and of the Norwegian or Icelandic annalists; the Saxon Chronicler and other contemporary writers of that nation speak of them under the names of *Peohtas, Pyhtas, Pihtum,* and *Pehiti;* the Welsh historical fragments call them *Phichtjaid;* the Icelandic writers, *Pets;* the antient Irish annalists, *Cruithne*—a name which, differing as it does from the others that have been enumerated, is sufficiently ascertained to indicate the same people: and popular tradition in Scotland still remembers them under the name of *Pechs* (pronounced with a deep and prolonged guttural intonation), which is probably as near their true name as any of the other forms.

The main dispute with regard to the Picts, as with regard to the Caledonians, with whom they have been sometimes identified, the Scots, the Cimbri of antiquity, and the Cymry or modern Welsh, the Belgæ and the Irish Firbolgs, has been, whether they were a Celtic or a Teutonic people. Their Teutonic lineage is maintained by Usher, Stillingfleet, and Pinkerton; that they were Celts is the opinion of Camden, Bishop Lloyd, Father Innes, George Chalmers, Ritson, and others. The historic evidence that bears upon the point does not amount to much; all that can be said is, that the various old legendary accounts all make them to have come to Britain from Scythia or from Scandinavia. But the most curious and valuable fact that we possess in relation to this matter is, that their language appears to have nearly resembled the Welsh. One Pictish word only has been expressly mentioned by any old writer. *Peanvahel*, Bede tells us, was the Pictish name of the place at which the wall of Antoninus terminated on the Forth, and which Nennius says was called in Welsh *Pengaaul* (Pengual?), and in Scotch (*Scotice*) *Cenail*. It is still in fact known by the name of Kinneil. *Cen*, or *Cean*, is the Irish or Gaelic word for a head, and Cenail in that dialect would mean the head of the wall; and that is also the signification of the Welsh name, with which the Pictish is evidently identical.[*] And generally it appears that the antient names of places in those parts of Scotland formerly occupied by the Picts are Welsh, as was long ago pointed out by Camden, and has been since more fully established by the late George Chalmers, in his 'Caledonia.' On the other hand, it is remarkable that the most antient names of places in Wales are not Welsh, but Irish. This was stated by Humphrey Lhuyd nearly three centuries ago, and is, we believe, generally admitted by Welsh antiquaries. These two facts put together would lead to a suspicion, which is not uncorroborated by other circumstances, that the same people which formerly occupied Pictland in North Britain, or a people of the same race, are now the occupants of Wales, where they had displaced or supervened upon a previous population speaking the same language with the Celts of Ireland and the Highlands of Scotland; in other words, that the modern Welsh are a remnant of the Picts. This was the opinion of the judicious Camden. If the Welsh, who have always called themselves *Cymry*, are the Cimbri of the antient Cimbric Chersonese, now Jutland, this lineage would account for the Scandinavian or northern origin assigned to the Picts by the uniform testimony of the Saxon, the Irish, and the Icelandic annalists.

The greatest diversity of opinion has also prevailed as to the extent of the territory occupied by the Picts in the north of Britain. Pinkerton, who considers the Picts to be the same people with the Caledonians, holds them to have occupied not only the Orkney Islands and the Hebrides, but the whole of Scotland to the north of the Frith of Forth and Clyde, and to have extended their conquests on the east coast as far south as to the Humber. There is every reason indeed to believe that they were at one time in possession of a considerable territory to the south of the Forth. Bede expressly states that in his time the English held possession of the Pictish province in which stood Aebbercurnig, now Abercorn, in West Lothian, the seat of one of their bishops. Here too was Peanfahel, now Kinneil; and Edinburgh, farther to the east, on the same side of the Forth, is also described by old writers as having been at one time within the dominion of the Picts. But, at least during the greater part of the time that it subsisted, the Pictish kingdom appears to have been bounded by the Frith of Forth to the south, and to the west by the mountainous range still separating the Lowlands from the Highlands of Scotland. The kingdom of Strath-Clyde, or Cumbria, however, or Reged (that is, the kingdom, by way of pre-eminence), as it was usually designated by the Welsh, which comprised the south-west of Scotland, and perhaps also the county of Cumberland (if that did not form a separate state), must be regarded as having also been Pictish on the hypothesis which assumes the Picts to have been the same people with the Welsh, the latter being admitted on all hands to be of the same race with the people of Strath-Clyde.

The history of the Pictish kingdom established in the north-east of Scotland is, as may be supposed, exceedingly scanty and obscure. The Scottish and Irish chronicles however supply five different lists of the Pictish kings, no one of which evidently has been copied from another, although they all agree substantially, with the exception of such variations as tend to establish the independent authority of each. From these lists Pinkerton has framed a Pictish chronology, which he divides into two portions: the first, which he entitles Poetical, extending from the foundation of the monarchy by Cruthen, or Cruidne (whence the Irish name for the Picts), about A.D. 28, through a succession of thirty-six kings, ending with Talorc I., A.D. 414; the second, styled Historical, extending from the accession of the successor of Talorc, Drust the Great, through forty princes more, to the subversion of the monarchy in A.D. 843, in the reign of Brudi VII. Besides the succession of the kings, a few events of Pictish history are also recorded by the Irish and Icelandic, as well as by the less antient Scottish chroniclers. These consist chiefly of the foundations of a few towns, and of battles fought with the Scots, or Irish colonists of the north-west of Scotland, with whom the Picts appear to have been almost constantly at war from the first establishment of these new settlers in the country about the beginning of the sixth century. Bede and Ailred state that the Southern Picts were converted to Christianity by St. Ninian about the year 412; but it may be doubted whether these were the Picts living between the Forth and the Grampians, as Bede affirms, or the people of Strath-Clyde, among whom it is known that Ninian was established as bishop of Whithern, now Whitehorn, in Wigtonshire. The conversion of the Northern Picts is attributed to St. Columba, about the year 565.

---

[*] It is remarkable that in Angus, and the other counties on the north east coast of Scotland where the Picts were longest established, the popular speech is still characterised by the peculiarity of the substitution of the element *f* for *w*, or *wh*, or *gw*. Thus, for *what* the people of that district all say *fat*, just as their Pictish ancestors for Pengual said Penfahel or Penfal.

No passage of the obscure story of the Picts is involved in greater darkness than the sudden catastrophe which appears to have put an end to their dominion in their principal seat, the north-east of Scotland. The common account of the Scottish historians is, that the Pictish kingdom was conquered in the year 843 by the Dalriadic or Scottish king Kenneth II., who thus, for the first time, united the whole of North Britain into one monarchy. The oldest authorities for this account are the Chronicon Regum Pictorum, written apparently about the beginning of the eleventh century (it comes down to the year 992), and first published by Father Innes in 1729; and the Register of St. Andrews, written about 1130. On the other hand it is extraordinary that no allusion should be made to any revolution as having taken place in Pictland about this time, either by Nennius, who wrote about 858, and who expressly states that the Picts then continued to hold a third part of Britain; by Asser, the biographer of King Alfred, who wrote before the end of the same century, and who speaks of the Danes ravaging the Picts in 875; by the Saxon Chronicler, by Ethelwerd, or by Ingulphus, who, in the tenth and eleventh centuries, all continue to speak of the Picts as an existing people; by the Irish annalist Tighernac, who wrote about 1088, and who continues a regular chronicle of the Pictish kings, among whom he reckons Kenneth himself, down to the death of his son Constantine II., in 875; by the Welsh annalists, who, in like manner, style Kenneth simply king of the Picts; or finally, by the singular genealogical poem, commonly called the Gaelic or Albanic Duan, belonging to the reign of Malcolm III. (1056-1093), which indeed does not mention the Picts at all, but passes over the reign of Kenneth II. without any remark. It thus appears that neither the Irish, the Welsh, nor the Saxon annalists who lived nearest to the time, ever heard of this subjugation of the Picts by the Scots, which the later Scottish chroniclers would have us believe amounted to the entire destruction of the Pictish nation, and indeed to the utter extirpation of that people from the soil of Scotland. Nevertheless, the fact remains unquestionable and undisputed, that Kenneth II., or Kenneth Macalpin, as he is commonly called, having been originally king of the Scots, or Dalriads, became king of the Picts about the date assigned to his conquest of that people; and the probability therefore seems to be that this Dalriadic king had a claim by descent to the Pictish throne, and that the contest in which he proved victorious was in fact not a war between the Scots and Picts, but merely a dispute between him and a rival claimant for the crown of Pictland, which terminated in its acquisition by Kenneth, and consequently in the union of the two kingdoms under one sceptre. Kenneth, we may here notice, appears to have followed up this success by a course of policy having for its aim the ultimate incorporation with his own dominions of the adjoining (perhaps Pictish) kingdom of Strath-Clyde; and that object was in fact accomplished, and the whole of what is now called Scotland brought (nominally at least) under one rule, in the year 973, in the reign of his great-great-grandson Kenneth III. Even down to a considerably later date than this however, a great part of the north-east of Scotland appears to have been actually held by Norwegian princes, who did not acknowledge the sovereignty of the descendants of Kenneth Macalpin; and even some of the great Highland chiefs of the west long continued to maintain almost as substantial if not as openly avowed an independence.

Certain singular architectural remains found in some parts of Scotland are still popularly known there by the name of Picts' houses: and the Picts, or Pechs, live in the traditions of the country as a people of almost superhuman strength and dexterity. This would seem to indicate the possession by that race of a more advanced civilization than belonged to the other races by whom they were surrounded. Many carvings on stone, of a very remarkable character, the prevailing emblems being a serpent with a zigzag line passing through it, and two or sometimes three circles united by double parallel lines, are scattered over the whole of the tract which once formed the dominion of the Picts; but these curious monuments have not yet received the investigation they deserve, and whether they are Pictish or Norwegian remains doubtful.

(An account of all the principal works relating to the Picts and the other antient inhabitants of Scotland which had appeared down to the date of its first publication, is given in the Introduction to Pinkerton's *Enquiry into the History of Scotland preceding the reign of Malcolm III.*, 2 vols. 8vo., London, 1789, and 2nd edit., Edin., 1814. Among the works upon the same class of subjects that have since appeared, the following are the most important: 'Caledonia, or an Account, Historical and Topographic, of Great Britain,' by George Chalmers, Esq., 3 vols. 4to., London, 1807-1824; 'Rerum Hiberniarum Scriptores Veteres,' edidit C. O'Conor, D.D., 4 vols. 4to., Buckingham, 1814-1826; 'Memoirs of the Celts, or Gauls,' by Joseph Ritson, Esq., 8vo., London, 1827 (but written before 1803), in the appendix to which is a Bibliotheca Celtica, or catalogue of books on Celtic Antiquities, extending to above 200 titles; 'Annals of the Caledonians, Picts, and Scots, and of Strath-clyde, Cumberland, Galloway, and Murray,' by the same, 2 vols. 8vo., Edinburgh, 1828 (also written before 1803); Dr. Pritchard's 'Researches into the Physical History of Mankind,' 2 vols. 8vo., 1826, and 2nd edition, 1837, and his 'Eastern Origin of the Celtic Nations,' 8vo., 1831; 'Thoughts on the Origin and Descent of the Gael, with an Account of the Picts, Caledonians, and Scots,' by James Grant, Esq. of Corrimony, 8vo., London, 1828; Sir William Betham's 'Gael and Cymbri,' 8vo., Dublin, 1834; 'The History of Ireland,' by Thomas Moore, Esq., vol. 1, 12mo., London, 1835; 'Britannia after the Romans,' 4to., London, 1836; and 'The Highlanders of Scotland, their Origin, History, and Antiquities,' by W. F. Skene, 2 vols. 8vo., London, 1837.)

PICTURE. [PAINTING.]

PICTURESQUE (in Italian *Pittoresco*, painter-like or picture-like, and therefore expressed in German by the word *Mahlerisch*, which is of exactly the same import) is that quality which peculiarly recommends objects for pictorial representation. Consequently, in order to ascertain wherein this quality consists, it is necessary to consider what it is that independently of other things contributes to the general effect of a picture, and recommends more particularly certain classes of objects as suitable for the pencil. A picture is a representation upon a plane surface of bodies in relief, described as they appear to the eye, by means of form and colour, and their accompanying light and shade, which degree of relief or illusion will generally be in proportion as the objects themselves are favourable to artistical execution on account of the apparent diversity and variety which they present to the eye, and with which they must accordingly be represented in painting, although in themselves, or taken separately, they may appear monotonous. Hence, provided any object presents that variety to the eye which the artist requires in order to display the *artifice* of his pencil, it matters not how unpicturesque it may be when otherwise viewed, or though it should possess in itself none of those qualities which are commonly insisted upon as essential to the picturesque. 'The ideas of *neat* and *smooth*,' says Gilpin, who is generally referred to as an authority upon this subject, 'instead of being picturesque, *disqualify* the object in which they reside from any pretensions to picturesque beauty.' Yet such theory ought to be upset and disqualified in turn; for how can we reconcile it with fact when we observe that many things which are remarkable for the very *smoothness* here objected to as a disqualification, are selected by the artist as being admirably suited for his pencil? Smoothness is one quality of satin and velvet; and the idea of smoothness, it may be presumed, and generally of uniformity of colour also throughout the material, is excited in the beholder; but then, in order to produce such appearance in painting, the artist must employ a great number of tints and colours; some of them quite different from the local or positive colour of the object itself, in order faithfully to express all the various modifications which the actual colour of the object receives from light, when seen as it is intended to be represented in the picture. For instance, in painting white satin, there will be comparatively little pure white—only on the high lights—but chiefly the middle tints, half shadows, reflexes, and full shadows, so that if that part of the canvas were cut out, it would appear only a rough blotched surface, like the stains on a weather-beaten wall, than which it is no less picturesque, and for the same reason, namely, on account of the variety and irregularity it presents to the eye in the breaking of the colours: and it is this kind of variety, not roughness or rudeness or irregularity in the thing itself, that, as far as colour is concerned, qualifies objects for pictorial representation.

Another opinion, which appears equally incorrect, is that the picturesque is something distinct from and opposed to beauty, whereas this is very far from being the case; for although there is an extensive class of objects which are disagreeable, and some of them almost disgusting in reality, and which yet become attractive in representation, where they are divested of all that renders them physically repulsive (such as beggars, hovels that seem the abode of penury and filth, &c.), there are likewise numerous others which, while they are beautiful in themselves, are far from being deficient in picturesque quality. It is true there are also not a few that are eminently delightful or beautiful in nature, yet become insipid in representation; but that is because they are deficient in that variety of colour and form which painting demands. A level well-kept lawn presenting a uniform surface of rich verdure is beautiful, that is, excites lively pleasurable emotions, but it is so far from picturesque that it is generally made use of as an argument to prove that neatness and smoothness are incompatible with picturesqueness. Such an object undoubtedly, when transferred to the canvas, does not produce a good effect, inasmuch as it then shows only as a monotonous surface of nearly unbroken green colour: this however is only true when no diversity is produced by treating the subject *picturesquely*. If we break its uniformity of surface by figures, by shadows, by gleams of light, by gradations of hue, though it will still convey the idea of being a level piece of grass, it will be divested of its monotony, and may even become picturesque, if it should produce a good contrast to other parts.

The same theory holds true with respect to *form*, it being by no means correct that objects are picturesque in proportion as they are irregular and devoid of symmetry. To say therefore, as Gilpin has done, that if we introduce a piece of regular architecture into a picture without any of the disfigurements occasioned by accident or decay, 'it immediately becomes a formal object and ceases to please,' is either a very erroneous or a very imperfectly expressed idea. Most undoubtedly, if it be shown merely in elevation, a structure which is symmetrical will produce a formal appearance: but then there is no occasion for its being so exhibited; on the contrary, by means of judicious foreshortening or perspective, of shadows thrown upon it so as to break up the too great equality of its masses, and by means of figures and other accidents, it may be made to present an agreeable species of irregularity to the eye, at the same time that it suggests to the mind the idea of the most perfect symmetry. If for instance we view a colonnade in front or parallel to the picture, it will undoubtedly be formal and monotonous, but if it is shown obliquely and from a near station, so as to be considerably foreshortened, though we still perceive that it is precisely the same as before, the columns all equidistant and equal in height, the representation is produced by unequal spaces and unequal heights; the horizontal lines vanish obliquely, the farther parts are diminished, and many are partially concealed or indicated only by those which are shown; besides which the whole may be so broken by shadows falling upon the object, that the contrast of the masses of light and shade is alone sufficient to remove whatever monotony might else exist. Therefore, although the term picturesque is applied, by way of distinction, to that class of objects which are well suited for painting, but possess qualities more or less disagreeable in themselves, and so far implies something distinct from if not absolutely opposed to beauty, it comprehends also another class, which, while they are beautiful in themselves, are accommodated to pictorial representation, inasmuch as, in order to produce their images upon canvas, there must be great contrasts and irregularities both in respect to form and colour. Surfaces perfectly smooth and of uniform colour in themselves, such as those of highly polished marble or metal, must be expressed by a variety of colours, and by sudden lights and shadows perfect regularity of form, by a distorted image of the object according to the laws of perspective; while the uniform hue of local colouring is variously modified, according to the position and distance of the object, by aerial perspective, and by light and shadow and reflected light: and in proportion as they afford scope for displaying the effects of both linear and aerial perspective, and the contrasts and changes of form and colour arising from them, will objects partake of the picturesque.

PICUMNUS, M. Temminck's name for a genus of birds placed by Mr. Swainson in his subfamily *Buccoinæ*, or *Barbuts*, in the family Picidæ. The form has, according to Mr. Swainson, the habit of *Asthcnurus*, Sw.; but the rictus is bristled, and the tail very short, and not projecting beyond the wings.

Example, *Picumnus abnormis*.

Locality.—Tropical Asia.

PICUS. (Ornithology.) [Picidæ.]

PIEDMONT, PIEMO'NTE, or PIE' DI MO'NTE, which means a country at the foot of mountains, is the old name of a district of North Italy which forms part of the Sardinian States. Piedmont Proper is bounded on the east by Monferrato, west by the Cottian Alps, which separate it from Dauphiné, south by the former marquisate of Saluzzo, and north by the Val d'Aosta. [Aosta; Monferrato; Saluzzo.] It has the title of a principality, and the eldest son of the king of Sardinia is styled Prince of Piedmont. But Piedmont is no longer an administrative denomination, that tract of country being included in the division of Turin, which is subdivided into the provinces of Pignerol, Susa, Turin, Biella, and Ivrea, which are described under those heads in this work.

The name of Piedmont however was also and is still occasionally used as a general denomination for that part of the continental territories of the king of Sardinia which is situated on the Italian side of the Alps, and between the Alps and the Ligurian Apennines, as distinguished from the other great divisions of the monarchy, namely, the duchy of Savoy, the county of Nice, and the duchy of Genoa. In this larger sense Piedmont includes a fine and extensive tract of country 120 miles long from north to south, from the Pennine Alps to the Ligurian Apennines, and between 90 and 100 miles in breadth. It forms a distinct geographical region, having natural boundaries and a peculiar physical character. It comprises the western or highest part of the basin of the Po, from the sources of that river to where it emerges from the hills of Monferrato and enters the great plain of Lombardy, including its numerous and large affluents, the Tanaro, the Stura, the Bormida, the two Dora, &c. It is a country of hills and valleys, being occupied by numerous offsets of the Alps and of the Ligurian Apennines, except towards the eastern borders, where it merges into the plain of Lombardy, on the side of Vercelli and Mortara.

During the middle ages this fine country was parcelled out into several feudal principalities and lordships, under a nominal allegiance to the German emperors as kings of Italy, namely: 1, the principality of Piedmont Proper; 2, the duchy of Aosta; 3, the duchy of Monferrato; 4, the marquisate of Saluzzo; 5, the county of Asti; 6, the marquisate of Ceva; 7, the lordship of Vercelli. In course of time the dukes of Savoy became possessed of all these districts, either by conquest or inheritance, the houses of the former lords having become gradually extinct. The possession of these provinces by the House of Savoy was acknowledged by treaties and by diplomas from the German emperors. (Agostino della Chiesa, *Corona Reale di Sa-*

voia.) In the last century the House of Savoy became possessed also of the extensive district called Novarese, which was formerly part of the duchy of Milan. [NOVARA.]

The country of Piedmont, generally speaking, is one of the most fertile, healthy, and pleasant in Italy. It produces corn, rice, Indian corn, wine, fruits in abundance, timber-trees, excellent pasture for cattle, hemp, and silk. Oil is not a produce of Piedmont. The system of irrigation has been long practised in Piedmont, and it is carried to considerable perfection wherever the slope of the ground and the vicinity of running water afford the opportunity.

The population of all Piedmont amounts to nearly two millions and a half, being about three-fifths of that of the whole monarchy, the island of Sardinia included. In no part of Italy is there so great a proportion of considerable towns containing from 3000 to 10,000 inhabitants. For further statistical details, see SARDINIAN STATES.

The inhabitants of the various districts included under the general name of Piedmont, although possessing shades of character, have many common traits of resemblance which characterise them as a nation distinct from their neighbours of Savoy, Genoa, and Lombardy. They all call themselves Piedmontese, and at times also Subalpini. They are generally a well-made race of men, spirited, warm-hearted, brave and highly susceptible of milit[illegible] discipline, and have long enjoyed the reputation of [illegible] the best soldiers in Italy. They are also loyal, frank, attached to their country and their sovereign, though by no means servilely disposed; they are religious, and the lower orders even superstitious. The country population is much under the influence of the clergy. The nobility, who are very numerous, consist chiefly of landed proprietors with a moderate rental, most of whom live in their respective provinces. The Piedmontese are susceptible and hasty; they are fond of conviviality, and are less distinguished for sobriety than the rest of the Italians, but they are also industrious and hospitable. Less poetical than the other Italian nations, they are more disposed to the positive and practical sciences, as well as to the mechanical arts. Piedmont has produced many men of science, mathematicians, engineers, good generals, natural philosophers, historians, classical scholars, and philologists. In our own times, Alfieri, Denina, Botta the best historian of modern Italy, the poet Silvio Pellico, the orientalist Peyron, the mathematician and astronomer Plana, and several others, deserve mention.

The Piedmontese dialect, which is the spoken language of the whole country, with some shades of difference in the various districts, is one of the most remote from the written Italian. It is in a great measure an offspring of the Romance language which prevailed in Southern Europe during the dark ages, and has considerable affinity to the Languedocien and other dialects of the south of France. The pronunciation is a mixture of French and Italian; it has the French sounds of the *u* and the *eu*, which Alfieri disliked so much; but at the same time the Piedmontese retain the Italian sound of the *c* and of the *j*, and when they speak French they find a difficulty in pronouncing the *ch* and the French *j*. The Piedmontese is also a written dialect, and is well adapted for poetry. Calvo and others have written poems in it, and Brofferio has lately published a volume of Canzoni (*Poesie Piemontesi del Medico Edoardo Calvo*, Torino, 1816; *Canzoni Piemontesi di Angelo Brofferio*, Lugano, 1839). A Piedmontese vocabulary, by Zalli di Chieri, was published at Carmagnola, 3 vols. 8vo., in 1815; and a more compendious one has been published by Michele Ponza, Torino, 1827.

PIEPOWDER COURT. [PIPOWDER COURT.]

PIER (from the French *pierre*, stone) the general name for the solid spaces between a series of openings in a wall, whether windows or arches; but in its technical meaning the term is more particularly applied to the pillar-like masses of masonry or brick-work from which arches spring, rising from what is termed the *impost* capping the pier, and which generally consists of a series of mouldings, although sometimes it is merely a platband, and occasionally the impost is omitted altogether, especially in rusticated basements. For the relative proportion between the breadth of the piers and the width of the arches, no rules either can or need be laid down, because it must be more or less regulated by circumstances, and we accordingly find very great differences in this respect in examples of equal authority, and consequently far greater diversity of architectural character is thus attainable than if any one fixed standard were constantly adhered to. Besides which, the bulk or breadth and thickness of piers must depend in a great measure upon the solidity required for the building and the weight they have to support. Still, as far as architectural beauty is concerned, the breadth of the piers should never be much less than one-third of that of the arches (supposing the latter to be open ones), otherwise the effect will be meagre and deficient in solidity of appearance; and in architecture excess of solidity even approaching to heaviness is generally a lesser defect than the contrary one. Much also depends not merely upon the width, but the proportions of the arches themselves, for if very wide, or less than twice their width in height, greater breadth is required in the piers than when the openings between them are of lofty or narrow proportion. In the external arcade or piazza [PIAZZA] of the old Royal Exchange, London, the piers were exceedingly narrow or slender compared with the arches, so much so as to be little more than square pillars or insulated pilasters with arches springing from them. It would be better therefore in similar cases to treat them altogether as such, converting their imposts into pilaster or antæ caps, as is occasionally done; for instance, in the arcade or loggia of the Southampton Railway Terminus at Vauxhall, where, but for such expedient, the piers would look offensively meagre.

Piers are frequently decorated with either pilasters or engaged columns, in which case their breadth must be such that the archivolt mouldings of the arches will fill up the space between the openings and the columns. In many instances columns are substituted for piers, placed either singly or in pairs; and the arches spring either immediately from their capitals or from an entablature over them. There are again many examples in which both piers and a lesser order or sub-order of columns are employed, the latter being insulated on each side of the pier, and their entablature forming the impost from which the arches spring. Palladio's Basilica, or Palazzo di Ragione, at Vicenza, affords an example of the kind, in which the faces of the piers themselves consist of a larger order in half columns, so that the whole composition resembles a series of what are termed arched Venetian windows entirely filling up the spaces between the larger columns. Besides these and other modes of decoration, niches are occasionally introduced as ornaments to piers.

In Gothic architecture (where open arches seldom occur except singly, in the exterior of buildings, as in gateways and porches), the insulated piers supporting what are distinguished by the name of pier-arches are not rectangular in plan, but splayed off or turned diagonally; and their splayed sides are broken into small attached pillars, or else moulded shafts, which latter are sometimes a continuation of the mouldings forming the arch, carried down without any interruption by capitals or horizontal mouldings to the shafts, yet sometimes terminating below in moulded bases; at others *dying into* or uniting with the plain surface forming the footing or general base of the pier.

The term pier is also applied to the solid masses supporting the arches of a bridge; with the exception of the extreme ones, which are distinguished by the name of abutments. [ABUTMENTS.] The piers of bridges have no impost mouldings, and they are carried quite through the structure, their depth being equal to the breadth of the bridge itself from the parapet on one side to that on the other.

Pier is likewise the name given to a mole or jetty carried out into the sea, whether intended to serve as an embankment to protect vessels from the open sea, or merely as a landing-place; for which latter purpose suspension chain-piers are now frequently employed.

PIE'RIA. [MACEDONIA.]

PIERRE, BERNARDIN DE ST., born in 1737, after studying at Paris, entered the department of civil engineers under the government, or 'ponts et chaussées,' as it is styled in France. A reduction however, which took place some time after, left him unemployed, and he entered the army as military engineer; but having quarrelled with his superior, he was dismissed from the service. He went to Malta with the promise of a commission, but found himself disappointed. He next visited Russia, where he found some friends who obtained for him a situation as engineer in the Russian service, in which he remained some time, and executed several surveys. He had drawn up the project of a colony of foreigners, to be established on the eastern bank of the Caspian Sea, with a republican government, under the protection of Russia. He presented his plan to the favourite Orloff, who told him coldly that such plans could not suit the policy of Russia. Becoming weary of that country, he went to Poland, with the intention of fighting against the Russians, but a love intrigue which he had at Warsaw detained him there for about a year without doing anything. From Poland he went to Dresden and Berlin, and at last returned to France, when the Baron de Breteuil procured him a commission as engineer in the Isle of France, or Mauritius, on the understanding that he was to proceed to the island of Madagascar to endeavour to realise there his favourite plan of a republican colony. While on the voyage he found out that his companions, instead of being intent on establishing liberty on the Madagascar coast, were proceeding thither for the purpose of procuring a supply of slaves. He quarrelled with them, and having landed in the Isle of France, he lived two years there, after which he returned to Paris, where he became acquainted with D'Alembert, Mademoiselle d'Espinasse, and other literary characters, who encouraged him to publish a narrative of his voyage. From that time his career as a literary man began. He afterwards wrote his pretty story of 'Paul and Virginia,' one of the best works of its kind in the French language, and which has established his rank among French writers. His other works are—1, 'Etudes de la Nature;' 2, 'La Chaumière Indienne;' 3, Harmonies de la Nature;' 4, 'A Narrative of his Journey to Russia;' 5, 'Essais sur J. J. Rousseau,' besides several plays. He had a situation under the government, when the Revolution broke out and again reduced him to poverty. The principles of the Revolution were however in accordance with his own theories of government, but when the reign of terror came he was in some danger, especially as he ventured publicly to profess his belief in God, which, in 1794, was considered by some of the ruling men as a ground of suspicion. At last he found a protector in Joseph Bonaparte, brother of the victorious general of the army of Italy, who generously assigned him a pension. Napoleon himself showed him kindness; he gave him the cross of the Legion of Honour, with a pension, and placed his son in a lyceum and his daughter in the Imperial school of Ecouen.

Bernardin de St. Pierre died in 1814. He was a kind of visionary for the greater part of his life, and his writings bear the stamp of his character. His works have been collected and published in two volumes, 4to., with his biography: 'Oeuvres de J. H. Bernardin de St. Pierre, mises en ordre par L. Aimé Martin,' Paris, 1836.

Bernardin de St. Pierre must not be confounded with Charles Abbé de St. Pierre, a philanthropist of the early part of the eighteenth century, known for his project of a perpetual peace, which he laid before the diplomatists assembled at Utrecht: 'Projet de Paix Perpetuelle,' Utrecht, 1713; also a 'Projet pour perfectionner l'Education,' and numerous other works, which Cardinal Dubois used to call the dreams of an honest man, but some of which however have been since acknowledged to be susceptible of being realised.

PIETISTS, the name given in the seventeenth century to a kind of German Methodists or Evangelicals, who, being members of the Lutheran Church, were dissatisfied with the cold dogmatism of the generality of its clergy, and felt the want of a revival of religious feeling and of practical piety and charity. Without separating themselves from the church, they instituted meetings called 'Collegia Pietatis,' from which the denomination of Pietists was derived. Philip Jacob Spener, a divine of the Lutheran Church, who was preacher at Frankfort and afterwards at Dresden and Berlin, was the chief promoter of these meetings, which began about 1670. He wrote several ascetic works, and died in 1705. [METHODISM.] A spirit similar to that of the Pietists of Germany has arisen in our own times in the Swiss and French Protestant churches, and the promoters of it, after suffering considerable annoyance from the less religious part of the community, have succeeded in effecting a revival of evangelical doctrines and practice. They have been styled in derision 'Momiers' (from *momerie*, mummery), a name which the great majority of them are far from deserving.

PIETRA MALA. [TUSCANY.]

PIGAFE'TTA, ANTONIO, born at Vicenza in the latter part of the fifteenth century, of a patrician family, applied himself to the study of mathematics and geography. Being highly interested in the discoveries which were then being made by Spanish and Portuguese expeditions, he set out for Spain in the suite of the papal nuncio to that country. Finding that an expedition was going to set out from Seville under the direction of Magalhaens, he asked and obtained of the emperor Charles V. permission to join it as a volunteer. The expedition sailed from S. Lucar in September, 1519. [MAGALHAENS.] Pigafetta, being a volunteer on board, and having no obligatory duties to perform, wrote day by day a journal of the voyage. Being gifted with a robust frame and healthy constitution, he bore the hardships and escaped the diseases which destroyed most of the crew. He was present at the landing on the Philippine Islands, where Magalhaens lost his life, and was wounded in the affray. He returned to Spain in the admiral ship Victoria, the only one that remained out of the five which had sailed together. He landed at Seville in September, 1522, having performed in the course of three years the first voyage round the globe. After repairing to church with his travelling companions in solemn procession and barefooted to thank God for their safe return, Pigafetta went to Valladolid, where he presented a copy of his journal to Charles V.

Pigafetta afterwards returned to Italy, and, at the request of Pope Clement VII., he wrote a more elaborate narrative of his voyage, with a description of the strange coun[illegible] he had visited, and short vocabularies of the languag[illegible] the Philippine and Molucca Islands. This narrative he dedicated to the grand-master of Rhodes, L'Isle Adam, and he sent a MS. copy to the Princess Louisa of Savoy, from which a French abridgment was made by a certain Fabre, and published at Paris without date. Of this abridgment, Ramusio inserted an Italian translation in the first volume of his 'Raccolta di Navigazioni e Viaggi,' fol., Venice, 1550. At last Amoretti discovered in the Ambrosian Library at Milan a complete copy of Pigafetta's original narrative, which he published, 'Primo Viaggio intorno al Globo,' 4to., Milan, 1800, with plates, drawn from the maps and sketches which accompanied the MS. Pigafetta's was the first account that Europeans had of the islands in the Pacific Ocean. Of Pigafetta's personal history after his return to Italy nothing is known, except that he was made a knight of the order of St. John. His house was still seen lately in his native town of Vicenza.

PIGEON PEA is the seed of the plant called, by Linnæus, Cytisus Cajan, and by De Candolle, Cajanus bicolor and flavus. It is a kind of pulse highly esteemed by all classes of the natives of India, and is by them regarded as holding the third rank among such articles of food. Cattle are said to be fond of the tender parts of the plant, whether green or dry. These two species, or varieties, form bushes resembling shrubs, but, according to Roxburgh, they seldom live more than two or three years, even if treated with the greatest care. The natives consider them annual, because they do not bear well the second year, and after collecting the first crop they pull the plants up for firewood. Cajanus bicolor grows from six to eight feet high, ripening its seeds in about nine months from the time they are sown, and producing about 600 fold; the other is much smaller, and yields in three months, but not more than 100 fold. The Telinga name of the first is Pedda Candi, and of the grain Pedda Kandiloo. (Roxb., *Fl. Ind.*, iii. 325.)

PIGEONS. [COLUMBIDÆ.]

PI'GHIUS, STE'PHANUS VINAND, born in 1520, at Kempen in the province of Overyssel, in the Netherlands, was nephew, on his mother's side, of Albert Pighius, a learned controversialist of the sixteenth century, who lived at Rome, and wrote against the Lutherans. Stephen Vinand, after studying in his native country and at Cologne, entered the ecclesiastical profession, and repaired to Rome, where he was well received on account of his uncle's reputation (his uncle being then dead), in honour of whom he added the name of Pighius to his paternal name of Vinand. He spent 8 years at Rome in studying antiquities, examining monuments, and copying inscriptions, &c. This labour was preparatory to the great work which he afterwards wrote on the Roman annals. On his return to the Netherlands he was made librarian to Cardinal Granvelle, after whose death he was appointed by the duke of Cleves preceptor to his son, with whom he travelled through Italy about 1575. The young man however died at Rome, and Pighius returned to his native country, and retired to the town of Xanten, of which he was a canon. He died in 1604, after publishing the first volume of his great work 'Annales Romanorum,' leaving the MS. of the remainder to the Jesuit Andreas Schott, who published the two following volumes. The full title of the work is 'Annales Magistratuum et Provinciarum S.P.Q.R. ab Urbe Condita, ex Auctorum Antiquitatumque variis Monumentis suppleti; in queis Reipublicæ Mutatiônes, Potestatum ac Imperiorum Successiones, Acta, Leges, Bella, Clades, Victoriæ, Manubiæ atque Triumphi, necnon inlustria Stemmata Familiarumque Propagines ad Annos et Tempora sua reducuntur,' 3 vols. folio, Antwerp, 1615. Pighius gives a chronicle of Rome year after year, from the building of the city, to the death of Vitellius, A.D. 69, the names of the consuls, tribunes, censors, ædiles, quæstors, prætors, proconsuls, proprætors, and other governors of the provinces, wherever their names can be ascertained from antient writers or monuments. He also notices briefly the principal events of each year, carefully quoting his authorities. Wherever an inscription bears upon a fact, he transcribes it. He also mentions the titles of the principal laws and senatus consultus, under their respective years. It is altogether a work of vast research and erudition, which cost the author more than twenty years' labour. His chronology has been found faulty, as most Roman chronologies are. (See Fortia d'Urban, in the French edition of Tacitus, by Dureau de Lamalle.) Pighius also published a good edition of Valerius Maximus, with valuable notes, Antwerp, 1585.

PIGMENTUM NIGRUM. [EYE.]

PIGNERO'L, or PINERO'LO, a province of the Sardinian states, bounded on the east by the province of Turin, on the south by that of Saluzzo, on the north by the province of Susa, and on the west by Mount Genèvre, which divides it from France. It is a mountainous region, being covered by offsets of the Alps, which form several valleys, through which flow the Chisone and other affluents of the Po. A road which crosses Mount Genèvre leads from Briançon in France to the town of Pignerol. A part of this province is occupied by the district of the Valdenses, consisting of three or four elevated valleys at the foot of Mount Genèvre. [VALDENSES.] The population of the province of Pignerol is estimated at 111,600 inhabitants, distributed among sixty-nine communes. (Serristori's *Statistica d'Italia*, 1835.) The principal towns are the following: 1, Pignerol, once considered a strong place, and still a garrison town, is a bishop's see; it has several churches and convents, a handsome cathedral, a large hospital, several manufactories of silk, woollens, and leather, and about 11,500 inhabitants. 2, Villafranca di Piemonte, situated in a fertile country near the confluence of the Chisone with the Po, contains 7600 inhabitants. 3, Cavour, with 6400 inhabitants. 4, Fenestrelle, in the valley of Pratgelat, at the foot of the high Alps, is a small town with about 800 inhabitants: it is only remarkable for its fortress situated on a bleak mountain, which was one of Napoleon's state prisons, and of which a full account is given by Cardinal Pacca, in his 'Memorie Storiche,' 2 vols., 1830. The cardinal was confined in the fort, together with numerous other state prisoners of various conditions, from August, 1809, to January, 1813, for his fidelity to Pope Pius VII. 5, Cumiana has 5000 inhabitants.

The province of Pignerol produces good wine, silk, and some corn; it also abounds in cattle. Chestnuts are plentiful in the mountains. The chamois, the wolf, and bear are found in the high Alps. (Neigebaur; *Calendario Sardo.*)

PIGNOTTI, LORENZO, born in 1739, at Figline in the Val d'Arno, studied medicine at Pisa, where he took his degree of doctor of medicine. After practising for some time at Florence, he was made professor of natural philosophy at Pisa, where he spent the greater part of his life, and died in 1812. His principal work is the history of Tuscany: 'Storia della Toscana sino al Principato, con diversi Saggi sulle Scienze, Lettere, ed Arti,' 9 vols. 8vo., which was published after his death. He begins his history with the antient Etruscans, and continues it through the long period of Roman dominion. He describes the vicissitudes of the Tuscan cities after the fall of the Western Empire, the glorious period of the independence of Florence, Pisa, and Siena, and concludes his work with the fall of the Florentine republic and the assumption of supreme power by the second house of Medici. Galluzzi has written the latter part of the history of Tuscany: 'Istoria del Gran Ducato di Toscana sotto il governo della Casa Medici,' 5 vols. 4to., Florence, 1787. Pignotti came late for his historical subject, after numerous and able writers who had treated the same matter either wholly or in part, and the historical portion of his work may be considered rather a compilation than an original composition, yet he contributed to it something new by means of his own researches into the archives and libraries. But the essays which he has added in distinct chapters appended to the political narrative, on the Italian language, on the art of war in the middle ages, on the revival of sciences, letters, and the arts, and on the commerce of the Tuscans, are all entirely his own. His sentiments are liberal in the genuine sense of the word; he is no party man; he always avoided controversial politics, and maintained his own independence of opinion. It is reported that the poet and improvisatore Gianni one day observed to Pignotti with a sneer, that the university of Pisa reckoned several asinine doctors among its members. 'That may be,' retorted Pignotti, 'we have heard of Caligula making his horse a senator.' The repartee consists in this: Napoleon had just made Gianni a senator of the kingdom of Italy, and the enemies of Napoleon used to nickname him Caligula, on account of some fancied resemblance between him and the medals of that emperor.

Pignotti wrote also a series of fables or apologues in Italian verse, which have been often reprinted. Pignotti is acknowledged to be one of the best Italian fabulists. He also wrote some odes and other poetical compositions: 'Poesie di Lorenzo Pignotti,' Florence, 1820.

Pignotti was buried in the Campo Santo of Pisa, where a monument has been raised to his memory.

(*Elogio di Lorenzo Pignotti*, by Antonio Benci, in the Florence *Antologia*, 1821.)

PIKE, the English name for a fish belonging to the order Malacopterygii, section Abdominales, family Esocidæ, and genus Esox. The pike tribe were regarded by Linnæus as forming a genus, but in modern works on ichthyology they constitute a family. They have no adipose fin, as in the Salmonidæ, and are distinguished by the upper jaw being formed chiefly by the intermaxillary bones: the maxillary are destitute of teeth, and concealed by the lips; the dorsal and anal fins are almost always opposite each other, and their intestine is short and without cæca. To this family belong the genera *Esox* (or pikes proper), *Galaxias*, *Alepocephalus*, *Microstoma*, *Stomias*, *Chauliodus*, *Salanx*, *Belone*, *Scomberesox*, *Hemiramphus*, *Exocetus*, and *Mormyrus*.

In the genus Esox the snout is broad and depressed; the intermaxillaries form about two-thirds of the upper jaw, and are furnished with small pointed teeth, as well as the lower jaw, the vomer, palatines, tongue, pharyngeans, and branchial arches; there is one dorsal fin, and that is placed opposite the anal fin. The *Esox Lucius*, or common pike, is found in the fresh waters of most parts of Europe, and Cuvier moreover states that it also occurs in North America, where however two other species are met with. Mr. Jenyns states that the common pike is probably indigenous, though usually supposed to have been introduced into England during the reign of Henry VIII. It spawns in March and April, and occasionally attains a weight of thirty, forty, or even sixty pounds. The pike is one of the most voracious of fishes, and, it is said, will even eat those of its own species.

The genus *Galaxias*, founded by Cuvier on the *Esox alepidotus* of Forster, and *Esox truttaceus*, Cuvier, differs chiefly from *Esox* in having nearly the whole edge of the upper jaw formed of the intermaxillaries; the body is apparently destitute of scales, the mouth slightly cleft; moderate and pointed teeth are observable in both of the jaws and also in the palatines, and there are a few strong hooked teeth on the tongue.

The genus *Alepocephalus*, founded upon a fish found in the Mediterranean, differs from the last genera in having the body covered with broad scales; the mouth is small, and the teeth minute and crowded; the eyes large, and the branchial rays eight in number.

Alepocephalus rostratus of Risso is caught at great depths in the sea before mentioned.

Microstoma is also founded upon one species, and that an inhabitant of the Mediterranean. It is the *Serpe microstome* of Risso; has a very short snout; the lower jaw projects beyond the upper one, and is furnished, as well as the small intermaxillaries, with very minute teeth; it has three large and flat branchiostegous rays; the eye is large, and the lateral line is furnished with a series of strong scales; there is but one dorsal fin, and that is placed a little behind the ventrals.

The genus *Stomias* contains two species, both of which are found in the Mediterranean, and are remarkable for their black colour with series of silvery spots; they have the muzzle very short, the mouth very deeply cleft, the opercula reduced to little membranous laminæ, and the maxillaries fixed to the cheek; the maxillaries, intermaxillaries, palatine bones, and tongue are all furnished with long and curved teeth; the body is elongated, and the ventrals are placed far back.

Chauliodus differs chiefly from *Stomias* in having two teeth in each jaw, each pair crossing with the opposite when the mouth is shut; the dorsal fin (which has the first ray elongated into a filament) is placed opposite the space which intervenes between the pectorals and ventrals.

Only one species of this genus is known; it is fifteen or eighteen inches in length, and of a deep green colour. This species, which is the *Chauliodus Sloani* of Schneider, is found at Gibraltar.

The species of the genus *Salanx* (Cuv.) are distinguished by their depressed head, the opercula folding beneath; four branchiostegous rays; the jaws short and pointed, and furnished with hooked teeth; the lower jaw somewhat elongated at the symphysis, and bearing a small appendage which is furnished with teeth—no teeth either on the palate or tongue.

Belone.—This genus is established by Cuvier upon the *Esox Belone* (Garfish) of Linnæus, and some other species differing from the true pikes in having the jaws much elongated and slender; the entire margin of the upper jaw is formed of the intermaxillaries; both jaws are furnished with small teeth, but there are no teeth in the other parts of the mouth; those of the pharynx are like paving-stones; the body is much elongated, and furnished with scales, which however are indistinct except on the lateral line. [GAR-FISH.]

Scomberesox.—In this genus (which is instituted by Lacépède), as in *Belone*, the body is elongated and the snout very long and attenuated, but the species may be distinguished by the dorsal and anal fins being divided, and forming as it were a series of small fins situated on the upper and under side of the body near the tail. The Saury Pike, or Skipper (Scomberesox Saurus, of Flemming), belongs to this genus.

The species of the next genus (*Hemiramphus* of Cuvier) have the body elongated and slender, the lower jaw slender and much elongated, as in *Belone*, but the upper jaw is remarkably short; both upper and lower jaws, so far as they are opposeable, are furnished with small teeth. One species of this curious genus has been found on the British coasts, and is described by Mr. Yarrell in the 'Magazine of Natural History,' for October, 1837; a figure and description is also given by the same author in the 'Supplement to the History of British Fishes.'

Genus *Exocetus*, Linn.—The species of this genus are at once distinguished from other *abdominales* by the enormous developement of their pectoral fins, which are formed like wings, and enable these fishes to support themselves for a short time in the air, a circumstance which has given rise to the name of flying-fishes. Their head and body are covered with tolerably large scales, and a longitudinal ridge, formed by carinated scales, is observable on each side of the belly; the head is flat above, and the muzzle is very short and obtuse. [FLYING-FISH.]

Mormyrus, Linn.—The fishes of this genus have the body oblong, compressed, and covered with scales; the head is covered by a thick skin which envelopes the opercula and branchial rays, leaving no opening in the latter but a mere vertical fissure; the opening of the mouth is small; slender teeth emarginated at the end, are observable on the intermaxillaries and lower jaw.

These fishes inhabit fresh water, and several species are found in the Nile and some other rivers of Africa.

PILASTER. [COLUMN.]

PILATE, PONTIUS, is chiefly known by the part which he occupies in the New Testament history. Nothing is recorded of his extraction. Some of the early Christian writers have dwelt upon the etymology of his names, and have supposed them descriptive of his character, but, as Bishop Pearson says, 'in vain.' They appear to be simply the nomen and cognomen of the Romans, as Pontius Aquila, Pontius Herennius, and Julius Cæsar. Pilate was a man of the equestrian order, and he was appointed governor of Judæa by Tiberius, A.D. 26. By the variety of terms used to designate Pilate in this office, it seems difficult to understand precisely the nature of his governorship. Tacitus calls him procurator; Philo Judæus and the Greek fathers *ἐπίτροπος*. In the Greek Testament he is called *ἡγεμὼν*, and in Josephus both *ἐπίτροπος* and *ἡγεμὼν*. In the Vulgate he is named praeses, which Wiclif, translating from that version, renders 'the justice.' Tyndale translates the Greek *ἡγεμὼν*, *the debite.* In King James's translation he is called governor, and so also in the Rhemish translation. Dr Campbell calls him procurator, and probably this is the best word to point out the office of Pilate, though it is evident that the power of life and death, which he had over the Jews, exceeded that which procurators usually possessed.

The character of Pontius Pilate is sufficiently developed in the New Testament. Philo Judæus and Josephus represent him in a similar light, as a self-willed, avaricious, and hard-hearted man. Josephus states moreover that the Samaritans, having been treated by Pilate with great barbarity, made a complaint to Vitellius, governor of Syria, who ordered him to Rome, to give an account of his conduct to the emperor. This was after he had been procurator of Judæa ten years. Before he arrived at Rome, Tiberius was dead; but Eusebius and others relate that Pilate was banished to Vienne in Gaul, and that, unable to endure his disgrace, he killed himself with his own hand, about the year 38.

(Philo Judæus, *De Legat. ad Caium;* Josephus, *Antiq.* and *De Bello Jud.*; Eusebius, *Hist.*, b. i., c. 7, with the note of Valesius; Pearson, *On the Creed.*)

PILÂTRE DE ROZIER. [BALLOON.]

PILCHARD. [CLUPEIDÆ.]

PILCHARD FISHERY. [FISHERIES.]

PILCOMAYO. [PLATA, LA, River.]

PILE'OLUS. [TROCHOIDEA.]

PILEO'PSIS, Lamarck's name for a genus of mollusks (*Capulus* of De Montfort, which name has the priority whose place in the system was long doubtful.

The form was arranged by Linnæus under his genus *Patella*, with the name of *Patella Ungarica.*

Lamarck divided his genus *Pileopsis* into two sections the first consisting of those species whose shell was without any known support (*Pileopsis*, Lam., *Capulus*, Montf.); the second consisting of those species whose shell had a known support (*Hipponyx*, Defrance).

Mr. G. B. Sowerby, when treating of *Hipponyx* (*Genera*, No. i.), differs from Defrance, who first proved that the shell consisted of two parts, but still considered it as a univalve which had the property of making a support for the purpose of raising itself above the shells or stones to which it is attached. Mr. Sowerby states (*loc. cit.*) that he sees nothing in the nature of *Hipponyx* different from other bivalves; on the contrary, the numerous observations which he had made appeared to him only to strengthen the evidence in favour of a relation between this genus and the genera *Orbicula*, *Crania*, and *Terebratula;* and he adds, that he suspects that the animal has, in common with those genera, two fringed arms or tentacula. The same author, in his description of *Capulus* (*Pileopsis*, Lam.), (*Genera*, No. xxxviii.), observes that this genus may be regarded as a remarkable instance of the importance of a correct knowledge of the animal which forms it, as well as of the characters of the shell itself. He states that he had long entertained the opinion that the animal must be a gastropod, and consequently very different from that of Defrance's *Hipponyx*, which, in his opinion, is a truly bivalve shell. 'It may here be observed,' continues Mr. Sowerby, 'that in the bivalve mollusca the mantle envelopes the animal and lines the inside of the shell, depositing testaceous matter on its whole internal surface; the *Hipponyx* is therefore a true bivalve, for its animal must be wholly enveloped in its mantle, or testaceous matter could not be deposited on all sides; but in the present genus, which has been very erroneously united to *Hipponyx* by Defrance and Lamarck (on account, no doubt, of their general resemblance in form), there is a distinct head, with tentacula and eyes, and the branchiæ are arranged in a single row behind the head: there is moreover a small nearly circular foot, by which it is usually found adhering to oysters and other shells, stones, &c.; all which circumstances prove that it cannot produce a second valve, and that it is not therefore even related to *Hipponyx*. The shell itself also differs from the upper valve of *Hipponyx*, for in *Capulus* it is obliquely conical and curved backwards, uncinate, and somewhat spiral; in *Hipponyx* however, though it is obliquely conical, it is not recurved, nor is it in the least spiral. We are fully aware that in full-grown specimens of some of the *Capuli* the beak is not recurved; but we observe that in the young shells of the same species it is distinctly so. It is somewhat singular that, although the *Capuli* are gasteropods, they do not appear to remove from the spot to which they were at first attached, but, like several of the *Patellæ*, they seem to form, probably by a chemical action,* a more or less deep cavity in the surface to which they adhere; this circumstance alone should, as we think, be sufficient to distinguish the *Capuli* from the *Hipponyces*, for it is evident that an animal with a mantle capable of depositing testaceous matter cannot at the same time erode the spot to which it is affixing such calcareous deposit. But there is a circumstance in the peculiar form of the impression made by the foot of the *Capulus*, which, it appears, is difficult to understand; for the margin of this impression is sometimes more or less raised in a somewhat horse-shoe form, apparently corresponding to the muscular impressions in the lower valve of *Hipponyx*. We think this peculiar form may be caused by the contraction and expansion of the nearly circular foot in raising and depressing the shell, in order to permit the entry and egress of the sea-water.' There is much in this worthy of consideration; and we should remember that the author was not aware of the discoveries of the French voyagers, which have led to such a different conclusion, and, in short, to a confirmation of the original views of Defrance and Lamarck as to the relative place of *Pileopsis* and *Hipponyx* in the system.

M. Deshayes, in the last edition of the *Animaux sans Vertèbres*, remarks, that in treating of the *Pteropoda*, he had pointed out the error of Lamarck in considering them as intermediate between the *Acephalous Mollusks* and the *Mollusks properly so called*. M. Deshayes thinks, in accordance with the opinion of M. de Blainville, that if there exists a passage between these two classes of *Mollusca*, it is to be looked for in the genera *Pileopsis* and *Hipponyx*. The greater proportion of students in conchology, he observes, who for the first time compare the genera *Crania* [BRACHIOPODA, vol. v., p. 314] and *Hipponyx*, find a great relationship between them, and have a tendency to approximate them in arrangement. But the relations which exist between the shells not being continued in the animals which inhabit them, it becomes necessary for them to abandon this supposed approximation, on the ground that one of the genera (*Crania*) belongs incontestably to the *Brachiopoda*, whilst the *Hipponyces* are true acephalous mollusks. When the organization of the *Hipponyces* is compared with that of the *Acephala*, the observer finds with surprise that the strongest relations exist in reality between these two classes of animals.

The short description, continues M. Deshayes, given by Cuvier, in the *Annales du Muséum*, of *Pileopsis*, is the only one known at present; and this description teaches us that the animal, attached to its shell by a muscle in the shape of a horse-shoe, is provided with a foot comparable with that of the *Patellæ*; that it has a rather large cervical cavity containing a pectinated branchia comparable with that of the *Crepidulæ*; and finally, that it has a proboscidiform head, with two tentacles with eyes at their base. Observation has long demonstrated that the true *Pileopsides*, though they live after the manner of the *Patellæ*, are still more sedentary than the latter; for there may be seen, in certain individuals of the *Pileopsis Ungarica*, irregularities proceeding from the body on which it has lived when young continuing exactly the same to adult age—irregularities whose traces may be observed on the lines of growth, and which prove, in the opinion of M. Deshayes, that during its whole life the animal has never changed its place. This mode of existence approaches closely to that of *Hipponyx*. The latter genus, established by Defrance, was considered by Lamarck to be merely a section of the *Pileopsides*. Other zoologists, M. de Blainville among them, resting on new facts, adopted the genus of Defrance, and placed it in the neighbourhood of *Pileopsis*. M. Deshayes however thinks that it will nevertheless be possible, after a close examination of the two genera, to return to the opinion of Lamarck, and thus supports it.

The *Hipponyces* have a shell resembling that of the *Pileopsides*, but their delicate foot assumes the properties of the mantle, and becomes a secreting organ, producing a more or less thick calcareous support, on which the animal is attached by the same horse-shoe-shaped muscle which is inserted in the shell. The animal of *Hipponyx* then remains necessarily attached, after the manner of the *Oysters* and *Craniæ*, to submarine bodies. This manner of life in a cephalous mollusk, and the property which it possesses of secreting a support, gives it a resemblance to a bivalve shell without a hinge. This support, which is very thick in some species, diminishes insensibly in others, and sometimes becomes very delicate. M. Deshayes states his knowledge of certain species which, instead of secreting a support, attach themselves to other shells, and thereon hollow out to some depth the place on which they live. This impression offers exactly the same form and the same accidents as the more or less thick support above noticed. Between these species and those which live sedentary, without leaving any trace on the body which has served them for a resting place, there exists but very little difference; and it is to be presumed that there is no considerable discrepancy in the organization of the animals. Thus, in his opinion, the passage between *Pileopsis* and *Hipponyx* is established, and the opinion of Lamarck justified.

M. Deshayes goes on to state that the discovery of living *Hipponyces* having a support* is due to MM. Quoy and Gaimard, and that M. de Blainville, to whom these scientific voyagers, on their return from their first expedition, had sent some small individuals preserved in spirit, gives some interesting details relating to the organization of these animals. Afterwards M. Quoy, during his second voyage, had an opportunity of observing larger species, and he found that the *Patella Australis* of Lamarck was a true *Hipponyx* attached upon a very delicate calcareous support. In the highly interesting work published by M. Quoy at the conclusion of the voyage, that zoologist has given very complete details concerning the animals of this genus, which prove most evidently the great analogy which exists between the *Hipponyces* and the *Pileopsides*. The animal is comprised between two fleshy disks, one of which is formed by the mantle and the other by the foot, and when it is entirely detached, it resembles an acephalous animal enveloped in the two lobes of its mantle. But *Hipponyx* differs from the *Acephala* in many points: its head is slightly prolonged into a proboscis, and the mouth is armed with a short tongue, roughened as in the *Patellæ*. The œsophagus is surrounded by a nervous collar, bearing more resemblance to that of the Mollusks properly so called than to that of the Acephalans. These animals are completely hermaphrodites, which incontestably approximates them to the *Lamellibranchiata*;† but the branchial organ is very different, for it is pectinated and formed of straight and rigid lamellæ contained in a cervical cavity and directed from left to right. The *Hipponyces* have, as well as the *Pileopsides*, in front of the foot, vesicles which are more or less numerous, in which the *ova* are deposited, protected by the shell of the mother, and undergoing for a period, the duration of which is not known, a sort of incubation. As the *ova* increase in size, the vesicles diminish in number, but are augmented in volume. Such are the results of the observations made by M. Quoy.

M. Deshayes calls attention to the fact that many of the so-called *Patellæ*—*Patellæ Galathea* and *tricostata*, for example, should be placed among the *Pileopsides*; and that *Patella Australis* should be arranged with the *Hipponyces*.

Mr. Garner seems to be also of opinion that Lamarck has assigned its true place to *Hipponyx*. 'The Patella,' says the former, in his valuable paper *On the Anatomy of the Lamellibranchiate Conchifera* (*Zool. Trans.*, vol. 11), 'when sticking to a rock often forms a hole an inch in depth, and this by the action of its ciliated *branchiæ*; the hole cannot be made by the shell, as it fits exactly in it, and is of such a figure that no rotation can take place. The *Hipponyx*, another Gasteropod, forms cavities in the *Patella* and other shells to which it adheres.'

Mr. Swainson (*Malacology*, 1840) places both *Pileopsis* and *Hipponyx* under his tribe *Scutibranchia*, or *Limpets*.

---

* *Quære tamen*; and bear in mind the agency of currents of water produced by the action of *cilia*. [LITHOPHAGIDÆ, PHOLAS, &c. See also post, p. 155.]

* But note. The suspicions of Defrance that *Hipponyx* had a valvular support were confirmed not only by his finding the two valves together on the outside of a *Cerithium* (*C. Cornucopia*), but also by the discovery of an attached valve of *Hipponyx mitrata*. Mr. G. B. Sowerby states that about the same time he was almost persuaded of the same fact by an examination of the upper valve and a comparison which he instituted between it and some specimens of *Orbicula* and *Crania* which had just then fallen into his hands.

† It is now satisfactorily made out that most, if not all of these, with the exception of *Cyclas*, are diœcious.

He makes the genus *Hipponyx* succeed the genus *Emarginula*, and gives *Hipponyx* and *Pileopsis* as subgenera of the former.

Hipponyx. (Defrance.)

Generic Character.—*Animal* oval or subcircular, conical or depressed; *head* globular, carried at the extremity of a sort of neck, on each side of which is a tentacle convex at its base, and terminated by a small conical point; *eyes* placed on the tentacular convexity; *mouth* with two small labial tentacles; foot very delicate, thickened towards its borders, which lessen and enlarge like those of the mantle, to which it bears a complete resemblance; *branchiæ* situated above the origin of the back; *anus* at the right side of the cervical cavity; *oviduct* terminated in a large tubercle at the root of the right tentacle.

Shell conoid or depressed, the apex not spiral; *aperture* with irregular edges; cavity deep, with a muscular impression in the form of a horse-shoe; a rounded lamellar *support*, or an impression on the body serving as the resting place of the animal, presenting also a muscular impression of a horse-shoe shape. (Rang.)

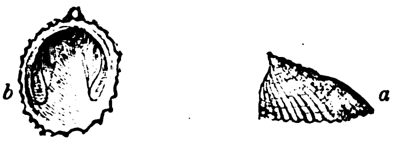
The number of living species given by M. Deshayes in his tables is six; in the last edition of Lamarck the number is three. These are *Hipponyces acuta*, *foliacea*, and *suturalis* of M. Quoy; the first from the seas of New Holland and the two last from the island of Guam in the archipelago of the Marianne islands. To these, according to his own showing, *Patella Australis* should be added; and also the *Patella mitrata* of Linnæus.

Habits, &c.—The genus is marine, and has been found attached to stones and shells at depths varying from the surface to sixteen fathoms.

Example, *Hipponyx acuta.*

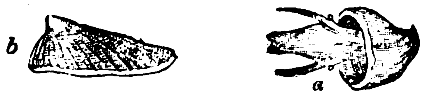
Description.—*Shell* solid, ovate, thickly striated longitudinally, the margin crenulated, violacescent; the vertex long, acute, and straight; white internally.

Locality.—The seas of New Holland.



Hipponyx acuta.

a, the upper valve in situ: *b*, inside view of the same.



Hipponyx acuta, var.

a, the animal; *b*, the shell in situ.

Pileopsis. (Lam. Capulus, Montf.)

Generic Character.—*Animal* conical, slightly spiral at the summit, furnished with a distinct *head* which has a proboscis terminating the *mouth;* in front of the anterior border of the *foot* is a double membrane forming numerous folds; the *tentacles* are nearly cylindrical, stout, obtuse, and carry the *eyes* on small convexities a little above their external base; *foot* large, but very anterior and delicate; *mantle* simple and without ornament; *branchial cavity* open anteriorly; *branchiæ* composed of many narrow and longitudinal laminæ, which adhere by a single transversal line to the *plafond;* orifice of the *anus* towards the right side of that cavity.

Shell irregular, conical, with the apex more or less inclined or spiral, directed backwards; aperture rounded, with simple, irregular, and continuous borders; cavity deep, offering a muscular impression in form of a horse-shoe, open anteriorly. (Rang.)

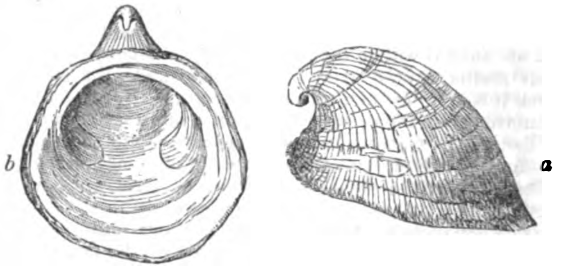
Habits, &c.—This genus, like *Hipponyx*, is entirely marine, and has been taken adhering to shells and stones at depths ranging from the surface to twenty fathoms. The Pacific, the East and West Indies, and the coasts of Europe, are the localities principally known.

The number of living species recorded by M. Deshayes in his tables is seven, and of these one, *Pileopsis Ungarica*, is noted as recent and fossil (tertiary): the number given in the last edition of Lamarck is six, to which, as we have seen, *Patellæ Galathea* and *tricostata* are to be added.

Example, *Pileopsis Ungarica.*

Description.—Shell conico-acuminate, striated; the vertex uncinate and revolute; aperture rather wider transversely; rosy within. The epidermis is somewhat horny, thick, and velvety.

Locality.—The Mediterranean and the shores of the Atlantic. Abundant on our own coasts. One of the best figures we know is given by Mr. G. B. Sowerby, in his *Genera* (No. xxxviii.).



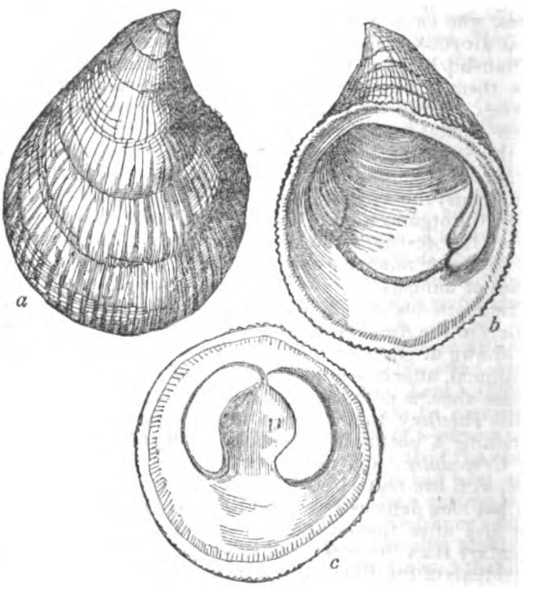
Pileopsis Ungarica.

a, the shell in situ; *b*, inside view of the same.

Fossil Hipponyces and Pileopsides.

Hipponyx. Lamarck has described some fossil species among the *Patellæ* under the name of *P. Cornucopia* and *P. dilatata;* and Mr. G. B. Sowerby (*Genera*) states that all the species known are from the calcaire grossier: (but see below).

The number of fossil species (tertiary) recorded by M. Deshayes in his tables is twelve, and a 'new species' is noted as both living and fossil (tertiary). The localities for these fossils are Sicily, Italy (Subap.), Bordeaux and Dax, Touraine and Turin. Paris is given as the locality for eight. In the last edition of Lamarck six is the number recorded, including *Hipponyx Cornucopia.*



Hipponyx Cornucopia.

a, external view of the upper valve; *b*, internal view of the same; *c*, inside of lower valve.

Pileopsis. Mr. G. B. Sowerby states that he is not acquainted with many recent species, but that several are common among the fossils of the tertiary beds. M. Deshayes, in his tables, gives the number of fossil species (tertiary) as six, *P. Ungarica* being both recent and fossil (tertiary, Baden); the other localities being Sicily, Italy (Subap.), the English Crag, Bordeaux and Dax, and Touraine.

Professor Phillips records *Pileopsis ? trilobus*,* *P. tubifer*, *P. striatus*, *P. neritoïdes*, *P. vetustus ?* and *P. angustus*, from the mountain-limestone formation of Yorkshire and other districts. (*Illustrations of the Geology of Yorkshire*, part ii.)

Mr. Murchison, in his catalogue of the shells of the middle Ludlow rock, records the only imperfect specimen yet obtained from the Aymestry limestone: the aperture appears less expanded than in the *Pileopsis vetusta* of the carboniferous limestone. (*Silurian System.*)

---

* Pileopsis is generally considered to be feminine,

PILES, ROGER DE, who belonged to one of the best families in that part of France of which he was a native, was born in the year 1635, at Clamecy, in the province of Le Nivernois, which is now the department of La Nièvre. His parents neglected nothing to give him a solid education, but as he evinced a most decided inclination for the art of painting, he was allowed to follow the bent of his genius. Circumstances however prevented him from devoting himself exclusively to his art. Having been engaged by president Amelot, in 1662, as tutor to his children, he accompanied young Amelot to Italy, and on his return published some essays on painting. He was an intimate friend of Alphonse Dufresnoy, whose Latin poem on painting he translated into French, with explanatory notes. Amelot de la Houssaye, his pupil, having been appointed ambassador to Venice, De Piles was employed as his secretary of legation. He also accompanied him on some other missions: thus he went to Lisbon in 1685, and to Switzerland in 1689, and had the honour to be the bearer to Louis XIV. of the treaty of Neutrality, which his ambassador had just concluded with the thirteen cantons. The reputation which he had acquired both in the arts and public affairs, induced Louis to send him to the Hague, under the pretext of following his profession as a painter, but in fact to enter into secret negotiations with a party in Holland which was desirous of peace. Being discovered, he was arrested by order of the Dutch government; and during his confinement he wrote his 'Lives of the Painters.' When he returned to France, a pension was granted him. Amelot being appointed ambassador to Madrid, De Piles accompanied him, but, his health being very indifferent, the climate of Spain did not agree with him, and he was obliged to return to Paris, where he died on the 5th of May, 1709.

Though his diplomatic occupations prevented him from devoting himself to the study of his art, he had acquired principles which in some measure compensated for want of practice. He was profoundly skilled in chiaroscuro, and there exist several of his portraits which are much esteemed, especially those of Boileau and Madame Dacier. His printed works are distinguished by a clear and unaffected style and refined taste; but his predilection for the Flemish school has sometimes rendered him partial in his judgments. His admiration of Rubens, in particular, was such, that he is said to have preferred him to Raphael. Besides his 'Lives of the Painters,' which have been translated into English, he wrote several other works on painting. A collection of the whole was published at Paris, in 1767, in 5 vols. 12mo. He likewise composed 'Abrégé de l'Anatomie accommodé aux Arts de la Peinture et de Sculpture,' Paris, 1667, fol., with plates, all after Titian. (*French Biographical Dictionary.*)

PILGRIM is the name given to a person who travels for the purpose of visiting the shrines or tombs of holy men, and the act itself is called Pilgrimage. The words pilgrim in English, *pellegrino* in Italian, *pèlerin* in French, are all corruptions of the Latin 'peregrinus,' which means a stranger or foreigner. Pilgrimages to Jerusalem, Bethlehem, and other places which were the scenes of the Saviour's life and death, and which are included in the general name of the 'Holy Land,' began at an early period, probably about the time of Constantine. We are told by Eusebius and others that Helena, Constantine's mother, proceeded on a pilgrimage to Palestine, and built the church of the Holy Sepulchre. The practice became common about the end of the fourth century, and we find it noticed as such by the fathers of the church, Jerome, Augustin, and others. Gregory of Nyssa, in one of his epistles, reproves the indiscriminate custom of pilgrimages, especially by women, who, he observes, were particularly exposed during a long and toilsome journey through countries like Syria, notorious for licentiousness of manners. He adds, that 'pilgrimages are not enjoined by the Scriptures; that the grace of God is not more abundant at Jerusalem than elsewhere; that grace is obtained by faith, and not by change of place; that were grace so plentiful at Jerusalem as people seemed to fancy, the inhabitants of that city would be strangers to sin; instead of which, all kinds of sin were common among them, and especially murder and lasciviousness.' He observes that he himself had once been to Palestine, but it was on a mission of his ministry to the churches of that and the neighbouring country of Arabia, and that he had a conveyance provided by the Imperial officers for him and his attendants; but, he adds, 'I found that my faith was neither increased nor diminished by the sight of Bethlehem and of the Mount of Olives. As I believed before in the mysteries of the Revelation, so I still believed after my visit.' There is much sober sense and sound religion in this letter, which is quite in accordance with the general character of Gregory of Nyssa. Some however have endeavoured to throw doubts on its authenticity; but the letter is quoted among the works of Gregory by Lippomanus, bishop of Methone, in his 'Lives of the Saints:' it is found among the other works of Gregory in an old codex in the Royal Library at Paris; and this account of Gregory's mission to Jerusalem is the same that is mentioned by him in another epistle to Olympius on the death of his sister Macrina. (*Gregorii Episcopi Nyssæ de euntibus Ierosolyma Epistola,* with a Latin translation by Stephanus, Paris, 1606; and again with notes, by P. Molineus, 1607.)

The opinions concerning pilgrimages contained in this epistle are in accordance with those expressed by other fathers of the church. St. Augustin says:—'The Lord did not say, Go to the East to seek justification; or, Sail unto the furthest West in order to obtain forgiveness. But he said, Forgive thine enemy, that thou mayst obtain forgiveness: I ask nothing of thee which is not within thee.' (Sermo III., *de Martyribus.*) Chrysostom, in his Homily I. to Philemon, says:—'In order to obtain forgiveness of our sins, it is not necessary to disburse money; it is not required to travel to distant lands, nor to undergo bodily labours and dangers; but an act of sincere will alone is required.' And Jerome, who was rather an advocate for visiting the Holy Land, yet observes, in his letter to Paulinus:—'The glory of Heaven can be attained from Britain as well as from Jerusalem. Anthony and the other holy monks of Egypt, Mesopotamia, and Armenia, have never visited Jerusalem; and the blessed Hilarion, although a native of Palestine, only visited Jerusalem once in his life. It is not according to places, but according to the internal faith that men are judged.'

In the course of time the practice of pilgrimage increased, and extended to other places besides Palestine. People resorted to the shrines of St. Peter and St. Paul at Rome, to that of St. Iago de Compostella in Spain, of St. Gregory of Tours in France, to the monastery of Einsiedlen in Switzerland, to our Lady of Loreto in Italy, to the tomb of Thomas à Becket at Canterbury, and to several other places.

The use of pilgrimages appears to have been introduced into the Spanish Peninsula about the eleventh century. The pilgrims went to the shrine of some saint, always on foot, and usually in the garb of penitence.' 'The most antient pilgrimage was to the shrine of St. Iago, to which hundreds of thousands from all parts of Europe resorted. The second religious journey was to Rome, to visit the sepulchre of St. Peter, and was then called "Romeria," a custom which may be referred to the eleventh century. The pilgrim to the holy city of Jerusalem, a journey undertaken by few in Spain, except those who wished to atone for some heavy crime, was called a 'palmer,' from the palm-leaf he bore in his hat, just as the pilgrim who had been to Compostella bore the scallop shell. It is doubtless to the influx of so many strangers from all parts that Spain is indebted for some of her numerous legends, and for the chief part of her chivalric lore.' (Dunham, *History of Spain*, b. iii., ch. 4.)

The pilgrimage to the Holy Land was the remote origin of the wars of the Crusades. [CRUSADES.]

In the west, the celebration of the Jubilee perpetuated the custom of pilgrimages to Rome. The institution of the Roman Jubilee is due to Boniface VIII. At the beginning of the year 1300, a report was spread at Rome that all those who should visit the church of St. Peter that year would obtain a plenary indulgence, and that every centenary year enjoyed the same privilege. Pope Boniface searched the antient records for the grounds of this report, and he interrogated a man 107 years old, who told him that in the year 1200 his father, a labouring man, had gone to Rome to get the indulgence, and had advised him, if he should live to the next centenary, to follow his example. Some other old men in France and Italy confirmed this tradition. After con suiting the College of Cardinals, Boniface issued a bull, stating that 'as according to the faithful report of the elders great indulgences are granted to those who visit the church of the prince of the Apostles every hundredth year, we confirm them, and grant plenary indulgence to all those who have confessed, and, being duly repentant, shall visit the churches of the Apostles during the present year, 1300, and every other centenary year after.' This is the origin of the festival which was afterwards called jubilee. Fifty years later, Clement VI. reduced the period of its recurrence to half a century, and styled it jubilee in commemoration of the jubilee of the Jews, which was celebrated every forty-ninth or fiftieth year, when all slaves became free, and all lands returned to their original owners. (*Leviticus*, xxv. 10, et. seq.) This jubilee began at Christmas, 1349, and it was attended by a prodigious concourse of people from all parts of Europe; it is said, more than a million at a time. Petrarca, who went to Rome on that occasion, speaks with wonder of the concourse of pilgrims. The crowd diminished during the heat of the summer, but increased again towards the fall of the year 1350, at which time the nobility, and especially the great ladies, from distant parts came. It appears that these ladies came by the road of the March of Ancona, where Bernardino da Polenta, lord of Ravenna, one of those robber barons of the middle ages, and his men, lay in wait for them, and ravished some of them, and obliged the rest to pay ransom. The chronicler who relates this adds, that 'had they remained at home, such mishaps would not have happened to them;' and that 'indulgences and pilgrimages are not suited to young ladies.' (P. Azar, *Chronica*, fol. 359.) Similar misfortunes are reported to have befallen those ladies who in former ages resorted to Palestine, when pilgrims were exposed to insults and even violence.

Many of the numerous foreigners who resorted to Rome in 1350, not knowing any language except their own, could not confess themselves, and were obliged to employ interpreters. In order to avoid this abuse the popes established the 'Penitentiarii,' or confessors who understand the principal European languages, and who are stationed in the church of St. Peter's, and empowered to give absolution in all cases, even in those generally reserved to the pope. The historian Matteo Villani (b. i., ch. 55), says that on the occasion of the jubilee of 1349, all the Romans had become innkeepers, that they charged enormously dear for everything, and that there was great scarcity, which added to the fatigues undergone by the poorer pilgrims, and the heat of the summer season thinned their numbers to a fearful extent. The cardinal Ceccano, legate of the pope from Avignon, wishing to shorten the stay of the pilgrims, abridged the time allotted for the performance of their devotions, but the people of Rome were so irritated against him for diminishing their chance of gain, that they obliged him to run away from Rome, and he died on the road to Naples, it was said of poison. (*Vita di Rienzi*, fol. 167; Matteo Villani, b. i., ch. 86.)

The period of the recurrence of the Jubilee has been altered several times; some popes reduced it to twenty-five years, in order that each generation should have the advantage of it. The last jubilee was celebrated at Rome in the year 1825, under pope Leo XII. There are foundations at Rome for receiving and feeding the poorer class of pilgrims who resort thither at jubilee time; one of these institutions or hospitals is called la Trinitá dei Pellegrini. The fashion of devotional pilgrimage however has very much decreased in our time. The popes granted to several monasteries the privilege of holding jubilee, with the indulgencies attached to it, every fifty years; among others to that of Canterbury. Concerning former pilgrimages, many notices are found in the antient chroniclers, especially those of the Crusades. Chaucer, in his 'Canterbury Tales,' has given sketches of the pilgrimage to Thomas à Becket's shrine. Henry Watson wrote 'Instructions for Pilgrims to the Holy Land.' Timberlake wrote the 'Travels of Two English Pilgrims to Jerusalem, Gaza, &c. For other particulars see COMPOSTELA; LORETO.

The Mohammedans have also their pilgrimages. According to a precept of the Koran, every Mussulman who possibly can, ought once in his life to visit the tomb of the prophet at Mecca and the Holy Kaaba. [MOHAMMED.] The ceremonies performed by the pilgrims at Mecca are related at length by Burckhardt, Ali Bey, and Planat. (*Histoire de la Régénération de l'Egypte sous Mehemet Ali.*) There are also sanctuaries for the Mohammedans of the sect of Ali at Mushed in Khorassan, and Koom in Irak Ajemi, which contains the tomb of Fatima, the sister of Iman Reza, which are visited yearly by numbers of Persian pilgrims

The Hindus also have their places of pilgrimage, the most celebrated of which is that of Juggernaut or Jagathnatha, on the coast of Orissa in Coromandel, where extensive buildings are allotted for the idol and his priests. The statue of the idol is brought forth at certain periods, and mounted upon an enormous car sixty feet high, which is dragged along by the devout multitude amidst crowds of pilgrims who resort thither from every part of Hindustan. The procession is attended by dancing girls and dissolute young men, who perform acts of obscenity, while fanatics throw themselves under the wheels of the car to be crushed to death. The whole scene, of which Buchanan and other writers give a full account, is a frightful compound of superstition, cruelty, and lust. The revenue derived from the tax on pilgrims is said to be trifling.

The Japanese also are said to have their pilgrimages to the temples of Xinto or Xaca, of which accounts are given by Thunberg and other travellers.

PILING OF SHOT, an instance in which a process of pure mathematics, the summation of series, becomes of immediate application. Three shot, or spherical balls of equal size, placed together on the ground, will support a fourth, and four will support a fifth. Not more than four can be placed together so as to touch each other and support one more. Hence arise two distinct methods of piling shot, the triangular and the rectangular.

In a triangular pile the base is an equilateral triangle, with one shot at the vertex, two adjoining, three in the next row, and so on. The number of shot in the base (supposed to have n rows) is therefore $1+2+3+\ldots\ldots+n$, or $\frac{1}{2}n(n+1)$. The number of interstices in which other shot can lie is $1+2+3+\ldots+n-1$, or $\frac{1}{2}(n-1).n$. If such a pile be completed until one shot stands at the vertex, the pile will be n layers high, and counting from the top, the layers will severally contain $1, 3, 6, 10, \ldots\ldots \frac{1}{2}n(n+1)$, of which the sum

$$\frac{n(n+1)(n+2)}{6}$$

is the number in a complete triangular pile.

Let there be a rectangular base, say of 16 by 11 The number of interstices is 15 by 10, and when the second layer is put on, the number of interstices is 14 by 9, and so on; whence the eleventh layer is a single row of 6. If a and $a+b$ be the numbers in the longer and shorter sides of the rectangular base, the number in the complete pile is

$$\frac{a(a+1)(2a+1+3b)}{6}$$

If the base be a square, $b=0$, and the number in the pile is

$$\frac{a(a+1)(2a+1)}{6}$$

PILLAR. [COLUMN.]

PILLAU, a seaport in the circle of Fischhausen in East Prussia, in 54° 33′ N. lat. and 19° 52′ E. long., was founded in 1772, and has only 3000 inhabitants besides 1000 in the fortress. It is situated at the extremity of a tongue of land or peninsula between the Baltic and the Frische Haff. [FRISCHE HAFF.] It is a place of considerable importance, for as the Haff is too shallow to allow large or heavily laden ships to go up to Königsberg and Elbing, they are either lightened of part of their cargo, or remain at Pillau, and the goods are conveyed to those ports by lighters (here called *Bordinge*), which also bring back the return cargoes. In the year 1839, 1420 ships cleared inwards, and 1439 outwards. Near to the town there is a strong fortress, which defends the entrance of the Frische Haff. Besides the employment afforded by the maritime commerce, Pillau derives great advantages from its fisheries, especially of sturgeons, from the roe of which caviare is prepared. About five miles from the Haff there is a fine forest of hornbeam, which is called the Prussian Paradise. To the north-west of the town begins what is called 'the Amber Coast,' this circle producing a greater quantity of amber than any other part of Prussia. In this circle too is the Kapora heath, where elks are still found. The winds on this coast often tear up the trees and drift the sand into heaps, so that the inhabitants are compelled to remove their habitations from one place to another. Near to Pillau there are two villages—Old Pillau, where there is a lighthouse 100 feet high, and Wogram, where there is a large building for preparing caviare. (Stein's *Handbuch*; Müller's *Wörterbuch*.)

PILLNITZ is a celebrated country-seat of the kings of Saxony, the usual summer residence of the court, near the village of the same name, and situated in a beautiful country on the right bank of the Elbe, about five miles from Dresden. Pillnitz was formerly an old castle. In 1693, the Elector John George IV. purchased it of Heinrich von Bünau, and made a present of it to his mistress, the countess of Rochlitz, on whose death it reverted to the crown. Frederick Augustus I. (Augustus II. as king of Poland) gave it, in 1705, to the countess of Cosel. It was afterwards the summer residence of field-marshal Rutowski. Augustus II. however chose to reside there himself, and built two palaces, which were magnificently fitted up, and were afterwards inhabited during the summer by the family of the king. Since the year 1788, the whole has been much improved, but the mixture of the Chinese, Japanese, and Italian styles of architecture gives it a singular appearance. Four detached pavilions form the four corners of a square, which is bounded on the west by the royal gardens, and on the east by the buildings of the old palace. Between the two southern pavilions stands the Water Palace, and between the two northern what is called the Berg Palace. The old palace, containing the temple of Venus, with the portraits of the beauties of the reign of Augustus II., was burnt to the ground in 1818. A new edifice has been erected on its site, which contains a spacious banqueting-room, adorned with fine paintings in fresco, by Professor Vogel, of Dresden, and partly lighted by a dome supported by twenty pillars. The palace contains also a chapel and a theatre. Behind the village there is a romantic valley called Frederichsthal, leading to the Borsberg, a mountain nine hundred feet high, from the summit of which there is a splendid view of the valley of the Elbe, from Meissen to Köningstein, bounded by the high land of Meissen, Bohemia, and the Erzgebirge.

Pillnitz has become famous in modern times for the congress of princes which met here from the 25th to the 27th of August, 1791, and at which the Emperor Leopold II., King Frederick William II., the archduke afterwards Emperor Francis, the crown-prince (the late King Frederick William III.) of Prussia, the count of Artois (Charles X.), the ex-minister Calonne, and the marquis de Bouille deliberated on the measures to be adopted against the French revolution. The congress did not conclude an offensive alliance against France, but it was resolved to act in common and to oppose any attack on the part of France. The defensive alliance between Russia and Austria, provisionally agreed on at Vienna, on the 25th of July, and definitively concluded at Berlin, on the 17th of February, 1792, was merely a subject of conversation at Pillnitz. The brothers of the king of France received, on the 27th of August, a declaration from Austria and Prussia, which the French considered as the foundation of the coalition against France. (Stein; Cannabich; *Conv. Lex.*; Engelhardt, *Sachsen*.)

PILLORY. The pillory was a mode of punishment for crimes by a public exposure of the offender, used for many centuries in most of the countries of Europe under various names. In France it was called *pillorie*, and, in more recent times, *carcan*; and in Germany, *pranger*. In England it existed before the Norman conquest, and was in frequent use in our criminal law from that period until within the last thirty years. It was finally abolished in the year 1837, by the statute 1 Vict., c. 23. In the laws of Canute (Wilkins's *Anglo-Saxon Laws*, p. 11) it was called *healfange*, or, more correctly perhaps, *halsfang*, *i.e.* catch-neck, a name derived, without doubt, from the form of the instrument used, and the mode in which the punishment was inflicted. Hence also the Latin name of the pillory, *collistrigium* (quasi collum stringens), is said to be taken. (Cowell's *Interpreter*, ad. voc. 'Pillory.') The tumbrel, *trebuchetum*, an obscure punishment, which is said to be the same as the ducking or cucking stool, and was used for women, who were exempted, on account of their sex, from the pillory, is often spoken of in the antient English laws in conjunction with the pillory. In early periods of English history, the right of having a pillory and tumbrel, and sometimes also *furcæ*, or gallows, within their jurisdiction, was claimed and insisted on as a beneficial franchise by lords of leets: in process of time this privilege was converted into a burthen for the public use; and such persons were held to be bound to maintain a pillory and tumbrel as appurtenant to their criminal jurisdiction, on pain of forfeiture of their franchises. (Hawkins's *Pleas of the Crown*, book ii., cap. 11, sec. 5.) In like manner the 'Droits de Carcan et de Pillori' are mentioned in antient French customaries as belonging formerly to seigneurs haut-justiciers. (Vouglans, *Loix Criminelles de France*, p. 66.)

The form of the pillory as used in England in the time of Henry VII., may be seen in a collection of prints published by the Society of Antiquaries. In modern times it was nothing more than a wooden frame or screen, raised several feet from the ground, and behind which the culprit stood, supported upon a platform, his head and arms being thrust through holes in the screen, so as to be exposed in front of it; and in this position he remained for a definite time, sometimes fixed by law, but usually assigned at the discretion of the judge who passed the sentence. The form of the judgment was that the 'defendant should be set *in* and *upon* the pillory.' In a case which occurred in 1759, an under-sheriff of Middlesex was fined fifty pounds and imprisoned for two months by the Court of King's Bench because, in executing the sentence upon Dr. Shebbeare, who had been convicted of a political libel, he had allowed him to be attended upon the platform by a servant in livery, holding an umbrella over his head, and to stand without having his neck and arms confined *in* the pillory. (Burrow's *Reports*, vol. ii., p. 791.)

The pillory was intended 'magis ad ludibrium et infamiam quam ad pœnam;' but serious injury, and, in some cases, loss of life, has occurred where the populace have been much excited against the offender. (Barrington's *Antient Statutes*, p. 56, note.) On the other hand, where the unpopularity of the prosecution or other causes have occasioned a feeling in the public mind favourable to the offender, the execution has sometimes been a species of triumph. This occurred in the case of Eaton, an aged person, who was convicted of an irreligious libel in 1812, at a period of much political excitement; and who, when exposed in the pillory, was received with demonstrations of respect and sympathy, the mob taking off their hats, and individuals offering him wine and refreshments.

The public exposure of the offender as a punishment is liable to many objections, besides the inequality of its operation; and the efficacy of all punishmentss which merely disgrace the offender has been questioned by some of the most distinguished modern writers on criminal law. (Rossi, *Traité de Droit Pénal*, p. 483; Haus, *Projet de Code Pénal Belge*, vol. i., p. 143.) In consequence of the recent direction of the public opinion to this subject, punishments of this kind have been lately withdrawn from most of the modern systems of penal law in Europe. In England the pillory was abolished in 1837, by the statute above referred to; in France, the carcan was discontinued upon the revision of the Code Pénal in 1832; and in the numerous codes and schemes of codes which have appeared in the different states of Germany during the last 10 years, punishments by public exposure of the person or otherwise tending generally to degrade the character have been omitted. (*Entwürfe für Würtemberg*, *Sachsen*, *Hannover*, *Baden*, &c.) It is remarkable that the Bavarian code of 1813, which is generally founded on just and enlightened principles of criminal law, and which formed the commencement of the series of improvements which have since taken place in Germany, contains the objectionable provision that a criminal capitally convicted shall, in certain aggravated cases, undergo a public exposure on the *pranger* for half an hour previously to his execution. (*Strafgesetzbuch für Baiern*, art. 6.)

PILOT. In many maritime countries the name of pilot is applied to a constant officer in a ship, who has the charge of the helm and the general direction of the ship's course; and also to a person who undertakes the special charge of navigating ships in particular rivers, roads, or channels, or in entering and leaving ports, and who is entrusted with such charge independently of the captains or masters, in consequence of his peculiar acquaintance with the navigation within the limits to which his duty is restricted. In France large vessels usually carry several officers of the former kind, who are called *pilotes hauturiers;* the latter description of pilot is called *pilote côtier*, or *lamaneur*.

The antient laws of France contained provisions for the education and regulation of both these kinds of pilots (Merlin, *Répertoire de Jurisprudence*, art. 'Lamaneur et Pilote;' Valin, *Commentaire sur l'Ordonnance de la Maine du Moi d'Aout*, 1681, tom. i., p. 483); but they are not mentioned in the Code de Commerce. In England the term is applied exclusively to officers of the latter description. By the laws of many maritime countries, taking a pilot to navigate a vessel on approaching port has been considered from early times to be obligatory on the master. Thus by the laws of Wisbuy, which were promulgated in the twelfth century, and were incorporated in the marine laws of most European countries, it was compulsory on the master to take a coast-pilot on board, though the merchant or master opposed it. (*Ordonnances de Wisbuy*, art. 44.) A similar provision is found in the *Consolato del Mare*. (Boucher, *Consulat de la Mer*, vol. ii., p. 429.) In this country, pilots are established at several ports for limited parts of the coast, who are appointed and regulated sometimes by acts of parliament, and sometimes by charters of incorporation; and in general the master of a ship engaged in foreign trade must put his ship under the charge of such a pilot, both in his outward and homeward voyage, within the limits of every such establishment. Pilotage in the Thames and Medway, and along the coast, from Orfordness to the Isle of Wight, excepting the jurisdiction of the Cinque Ports, has been for several centuries under the management of the corporation of the Trinity-house, and acts of parliament have been from time to time passed to regulate the Trinity-house and Cinque Port pilots. All these regulations were reconsidered by parliament in the year 1825, and the majority of them were consolidated in the statute 6 Geo. IV., c. 125, which contains also some general provisions respecting pilots in other parts of the kingdom. (Abbott *On Shipping*, p. 173, edit. 1840.)

PILSEN, a fortified town, the capital of a circle of the same name, is one of the principal towns in the kingdom of Bohemia. It is situated in the midst of fertile fields, in a beautiful and extensive valley, at the conflux of the Bradawka and the Beraunka, also called the Mies; in 49° 45′ N. lat. and 13° 25′ E. long. It is on the whole a well-built town, and the houses are mostly of stone. It has three suburbs, and 9000 inhabitants. The most remarkable public buildings are—1, the fine Gothic church of St. Bartholomew (probably built by the Teutonic Knights in 1292), with several fine paintings, and a steeple 180 feet high; 2, the elegant gymnasium; 3, the Gothic town-hall; and 4, the house of the Teutonic knights. Besides the gymnasium, there are a military academy, a philosophical institution, with six professors, and a lyceum. Pilsen has considerable manufactories of cloth and morocco leather. There are four annual fairs, which are much frequented by persons from all parts of the kingdom. The inhabitants carry on an extensive trade in the productions and manufactures of Bohemia, and in cattle, iron, potashes, feathers, wool, leather, cloth, &c. This trade has been much increased by the exertions of a patriotic joint-stock society, which has constructed an iron railway from Pilsen to the gates of Prague, where it divides into two branches, one of which goes to the river Moldau, by which the railway communicates with the Elbe; and as Pilsen is connected by the principal roads with the south and west of Germany, considerable quantities of manufactured goods and merchandise, brought up the Elbe from Hamburg, &c., are conveyed by the railway to Pilsen, where they are forwarded to their ulterior destination. This brisk trade, the fairs, and the presence of a numerous garrison, make this a very lively place. (Hassel; Stein; *Oester. Encyc.*)

PILUMNUS, Dr. Leach's name for a genus of brachyurous crustaceans.

Generic Character.—*External antennæ* setaceous, rather long, slender, inserted in the internal canthus of the eyes; *internal antennæ* situated in the transverse fossets of the *chaperon*. Third joint of the *external jaw-feet* nearly square, subtransverse, notched towards its end and internally. Second, third, fourth, and fifth pairs of feet terminated by simple sharp nails. *Carapace* transverse, truncated posteriorly. *Abdomen* of the females ellipsoïd and elongated. *Ocular peduncles* short and larger than the eyes; a fissure at the bottom of the orbit above and another below.

This genus very much resembles the *Crabs* properly so called; but differs from them principally in the number of pieces in the abdomen of the male, and is removed from them still further by the mode of insertion of the external antennæ.

M. Milne Edwards, who arranges the genus under his *Cancériens Arqués* [PLATYCARCINUS], is of opinion that *Pilumnus* approaches *Xantho* and *Pseudocarcinus* very closely. He divides the species, which are numerous, into several sections, according to the absence or presence of spines on the latero-anterior borders of the carapace, and according to the granular or spiny external surface of the pincers.

Example, *Pilumnus hirtellus*, Leach (*Cancer hirtellus*, Linn.).

Description.—Carapace with four or five dentilations on each of its latero-anterior borders; hands and carpus granulous above and externally; body pale yellowish mixed with brown or red in bands on the feet; both body and limbs bristly with brown stiff hairs. Size rather small.

Locality.—The coasts of England and France; generally found under stones. (Leach, *Malac. Brit.*, t. 12; Penn., *Brit. Zool.*, vol. iv., pl. 6, lower figure.)

PIMENTA, or **PIMENTO**, the produce of *Eugenia Pimenta*, a tree native of the West Indies, but cultivated almost exclusively in Jamaica, thence called Jamaica pepper. The unripe two-seeded berries, which are about the size of a pea, are dried by frequent turning in the sun, by which their colour is changed from green to brown or greyish-brown. Externally they are of a dull appearance, somewhat rough, crowned with the remains of the calyx, and frequently furnished with a little stalk. The shell is very brittle, about the thickness of a card, and encloses two seeds, which are roundish, dark brown, somewhat shining, and having a weak aromatic taste. The shell possesses an agreeable clove-like taste and smell. Two kinds are met with in commerce, English and Spanish, of which the former is the better.

Pimento berries are said to be adulterated with the berries or seeds of the Cocculus Indicus; these are larger, about the size of bay berries, extremely bitter, and, in large quantity, poisonous. This adulteration is scarcely credible, for the latter come from the East Indies, are dearer, and could only be successfully passed off when mixed with the powdered berries of pimento. The fraud may be detected by making an infusion, which, if pure, is not disturbed by tincture of galls or acetate of lime, which cause a precipitate when cocculus berries are present.

The shell appears to be the most efficient part, and to contain more of the active principles.

Bonastre obtained from them 10 per cent. of a heavy volatile oil, 8 per cent. of a green fat oil, an extractive containing tannin, resin, gum, and sugar; also a principle similar to caryophyllin.

By distillation an oil is procured which resembles oil of cloves, and which conducts itself in the same way towards alkalis.

As an aromatic stimulant, pimento stands intermediate between pepper and cloves, for the last of which, on account of its greater cheapness, it may often be substituted.

It is useful in dyspepsia dependent upon atony of the stomach, and in diarrhœa dependent upon a similar cause.

PIMPERNEL is the English name of the *Anagallis arvensis*, a little red-flowered prostrate annual found in cornfields. It is often called the Shepherd's or Poor Man's Hour-glass: it opens its flowers every morning about ten minutes past seven in these latitudes, and closes them a few minutes after two. If rain falls or the air is charged with moisture, the flowers do not open at all.

PIMPINELLA, a genus of umbelliferous plants inhabiting the meadows and mountains of Europe principally, is chiefly interesting on account of its comprehending among its species the Anise of the shops. This plant is an annual, with a smooth stem 1 to 1½ foot high; the lower leaves roundish, cordate, lobed, and both serrated and cut; those of the stems pinnated with wedge-shaped lanceolate segments, and the upper trifid, with the lobes undivided and linear. The flowers are small and white. The fruit is narrow, slender, rather hairy, with 5 filiform ridges to each mericarp. The latter is employed extensively as a carminative medicine, and for the purpose of flavouring liqueurs. The plant inhabits Egypt and the islands of the Grecian archipelago, especially Scio.

Of ANETHUM, formerly referred here by mistake, mention has already been made under DILL.

PIMPINELLA A'NISUM. [CARMINATIVES.]

PIN. This simple and well-known little instrument, when considered as an article of trade, is far from trivial, and its manufacture affords an admirable example of the principle of the 'division of labour,' for which purpose it has been employed by Mr. Babbage, in his introduction to the volume on mechanics, in the 'Encyclopædia Metropolitana,' to which we acknowledge our obligation for several valuable hints upon this subject.

It is not known at what time pins made of metal of the present form were first manufactured in this country, but it must have been some time previous to 1543, in which year a statute was passed (35 Henry VIII., c. 6), intituled 'An Acte for the True Making of Pynnes,' in which, after stating that much deceit had been practised in the making of pins, it was enacted that in future none should be sold but such as were well pointed and had the heads firmly soldered on to the stems, and further that the price charged should not be more than six shillings and eight pence a thousand. No mention is made of them in any previous statute, with the exception of an act of Richard III., which prohibited their importation from abroad, but the pins there alluded to were much larger than those now in use, and were made of box-wood, bone, or silver.

Pins of English manufacture being in great repute abroad, the foreign trade is very considerable, and the number actually made in this country daily has been stated at fifteen millions, an estimate which we are inclined to believe considerably below the actual quantity.

The most profitable mode of producing pins by hand labour seems to be by distributing the operations amongst ten persons, of whom four should be men, four women, and two children. By these means the manufacturer secures exactly the amount of talent requisite for his purpose at the lowest possible cost. The wages earned by these persons vary from 4½*d.* to 6*s.* a day. Now it is evident that a workman who could earn six shillings a day would be unprofitably employed, as regards the master, if he were paid at that rate to perform work of an inferior description, and which could be done as well by another person for smaller wages. Hence arises the necessity of dividing the operations in all manufactures among persons of different capacities, and of employing them in certain ascertained proportion. For pin-making then the number of persons employed should be ten, or any number that can be divided by ten without a remainder.

Ten persons can produce a pound, or about 5500 pins of medium size, in rather less than eight hours, each person taking up the work as soon as the operation preceding that which he or she has to perform is completed, and each being employed about a tenth part of the eight hours.

The cost of labour for producing such pound of pins is less than thirteen pence. The amount paid for labour alone in the production of this article in this country annually cannot be much short of seventy or eighty thousand pounds, to which must be added the cost of the material, carriage, profit, &c.,—an enormous sum considering the apparent insignificance of the article.

Manufacture.—The first thing to be done is to reduce a quantity of brass wire to the requisite size. This, though properly speaking a preliminary operation, is generally done in the pin-factory, as the wire is received of larger diameter than necessary. It is performed in the usual manner of wire-drawing, and the wire is then made up into coils of six inches diameter, and any dirt or crust which may be attached to the surface is got rid of by first soaking the coils in a diluted solution of sulphuric acid and water, and then beating them on stones. The next process is to straighten the wire, which is performed in the following manner:—Two short lines, parallel to and very close to each other, are drawn at one end of a board or table, and seven or nine pins are driven into the wood, at a short distance apart, alternately in the two lines. The end of the wire is placed between these two rows of pins and is thus held in a zig-zag position: it is then drawn between the pins to the other end of the table, and a length of about twenty feet is cut of. This process is repeated until all the wire is straightened and cut into similar pieces. A number of these lengths are then taken together, and by means of a powerful pair of shears, worked by the foot, they are cut up into shorter pieces, each a little longer than six pins. These latter pieces are then pointed at each end, in the following manner — The person so employed sits in front of a small machine, which has two steel wheels or mills turning rapidly. These wheels are usually about six inches in diameter, and their rims or cutting surfaces are about three inches broad. These rims are cut somewhat after the manner of a file, one coarse, for the rough formation of the points, and the other fine, for finishing them. Several of these pieces are taken in the hand, and by a dexterous movement of the thumb and fore-finger are kept continually presenting a different face to the mill, against which they are pressed. The points are then finished off by being applied in the same manner to the fine mill. After both ends of the pieces have been pointed, one pin's length is cut off from each end, when they are repointed, and so on until each length is converted into six pointed pieces. The stems of the pins are then complete. The next step is to form the head, which is effected by a piece of wire called the mould, the same size as that used for the stems, being attached to a small axis or lathe. At the end of the wire nearest the axis is a hole, in which is placed the end of a smaller wire, which is to form the heading. While the mould wire is turned round by one hand, the head wire is guided by the other, until it is wound in a spiral coil along the entire length of the former. It is then cut off close to the hole where it was commenced, and the coil taken off the mould. When a quantity of these coils are prepared, a workman takes a dozen or more of them at a time in his left hand, while with a pair of shears in his right he cuts them up into pieces of two coils each. To prevent them flying off from the shears when separated, the fore-finger of the left hand is applied to the tip of the coil, and the end thus cut off is caught in a bowl placed beneath it. In some factories this is performed by a chisel and gage, instead of the shears, and has the advantage of requiring less dexterity. The heads, when cut off, are annealed by being made hot and then thrown into water. When annealed, they are ready to be fixed on the stems. In order to do this, the operator is provided with a small stake, upon which is fixed a steel die, containing a hollow the exact shape of half the head. Above this die, and attached to a lever, is the corresponding die for the other half of the head, which, when at rest, remains suspended about two inches above the lower one. The workman takes one of the stems between his fingers, and dipping the pointed end into a bowl containing a number of the heads, catches one upon it and slides it to the other end; he then places it in the lower die, and, moving a treadle, brings down the upper one four or five times upon the head, which fastens it upon the stem, and also gives it the required figure. There is a small channel leading from the outside to the centre of the dies, to allow room for the stem. The pins are now finished as regards shape, and it only remains to tin or whiten them. A quantity of them are boiled in a pickle, either a solution of sulphuric acid or tartar, to remove any dirt or grease, and also to produce a slight roughness upon their surfaces, which facilitates the adhesion of the tin. After being boiled for half an hour, they are washed, and then placed in a copper vessel with a quantity of grain tin and a solution of tartar; in about two hours and a half they are taken out, and after being separated from the undissolved tin by sifting, are again washed; they are then dried by being well shaken in a bag with a quantity of bran, which is afterwards separated by shaking them up and down in open wooden trays, when the bran flies off and leaves the pins perfectly dry and clean.

Papering the pins for sale is the longest operation in pin-manufacture, with the exception of shaping and fastening on the heads. This latter operation consumes four hours, and the former more than two hours out of the eight required for producing a pound of pins. When the pins are separated from the bran, as before described, they are thrown into bowls, with their points in all directions, and before papering it is necessary to arrange them all the same way. This is done by laying a number of them upon a sort of comb, between the teeth of which they are caught by the head; they are then placed upon a piece of metal, with as many grooves as there are pins required in a row, and held there by another piece of metal being placed upon them. These pieces of metal are not quite so broad as the pins are long, so that their points project beyond the edge of the metal. The paper is folded into the required shape, and pressed against the points of the pins, which are then relieved from the holder, and the next row is arranged in like manner.

Of these operations, drawing the wire, cutting it into lengths, cutting the heads from the coils, and tinning, are performed by men, and the rest by the women and children. The fixing on the heads of the pins expeditiously and firmly has always been a matter of considerable difficulty, and many means have been resorted to and several machines invented to effect this purpose. Among the machines may be mentioned that of Mr. Rundy, for which a patent was taken out in the year 1809. This machine fixed on the heads in the old manner, but more firmly. Each head was fastened by one blow, and several pins were operated on at the same time. Since that time several other machines have been invented for forming the head out of the stem of the pin itself, by pressing a small part of the end of the stem into a hollow die. A large proportion of the pins now manufactured are made in this way, and are much superior to those made in the old fashion. One objection however has been urged against them. It is stated that to form the head in this manner by pressure, the wire requires to be very soft, and consequently the pins will easily bend. This certainly is a great disadvantage. We have seen some pins of which the heads were formed by curling the end of the stem round upon itself and then shaped by being struck in a die, but these would be open to the objection just mentioned. The only method that occurs to us of remedying this fault is to partly produce the head by an operation similar to that of wire drawing. The stem of the pin being drawn through the plate would be rendered much less liable to bend, and the head being half formed by such operation, but left soft, might be finished in a die as in the present machines. We are not aware that any method of this sort has been tried and therefore we merely throw it out as a suggestion.

We shall conclude by giving a slight sketch of the pin-making machine invented by Mr. Wright, and for which a patent was granted to him in May, 1824.

Motion is given either by manual power or by machinery to a strong axis working in collars. This main axis carries several cams or excentric wheels which put forward at each revolution as many levers or slides at right angles to the main axis. These levers return to their former situation as soon as the cam ceases to operate by means of a strong spiral spring attached to each; at the other ends of these slides the different operations are performed.

A coil of brass-wire of the requisite size is placed upon a reel and spindle, and the end is drawn through a set of zigzag pins as before described for straightening the wire, and placed between the teeth of a strong pair of pincers. This is all that is necessary to be done before setting the machinery in motion.

The first slide then moving forward shuts the pincers upon the wire and instantly carries it forward into a nipping-gauge which closes and cuts off sufficient for one pin. This length can be regulated by the adjustment of a small screw attached to the first slide.

The piece thus cut off is carried by an ingenious little adaptation called a carrier to the next operating slide. These carriers are four in number, mounted on a bar at right angles to the working slides and parallel to the main axis; this bar has a motion given to it in the direction of its length, and moves once for every pin-length of wire cut off by the gauge before mentioned. The carriers themselves are made somewhat in the manner of a pair of pliers, the under chap being kept up to the other by a spring. The juncture of these chaps is exactly opposite to the pin, which is forced between the chaps and carried to the next operation.

The piece of wire is deposited by the first carrier in the centre of a chuck attached to a small mandril, which by a moveable lever clutches the pin; the instant this is done, the frame which supports the mandril is tilted so as to bring the point of the pin down upon a revolving steel mill just below it; a lever or finger then presses the end of the wire upon the mill, and at the same instant the mandril carrying the pin is set in motion and the wire ground to a point; the mandril frame then rises, the mandril itself is brought to rest, the pin released, and conveyed by the second carrier to a finer mill, where the point is completed by exactly the same process as the preceding.

It is then taken by the third carrier to the first heading die, where the body of the pin is firmly held while a steel punch advances against the end of the wire, and forcing it into a hollow in the die, partially forms the head. The last carrier then takes the pin, and placing it in another die, the head is completed by another punch; a small forked lever then draws the finished pin from the die and drops it into a receptacle below. The pins are then tinned in the manner previously described. These operations are carried on by the machine simultaneously, and each occupies the same time; five pins being constantly under operation in the different stages; the machine will produce fifty or sixty pins per minute, and only requires the attendance of one person.

The reader is referred to the 9th volume of the *London Journal of Arts and Sciences*, where he will find a full description of the above machine, illustrated by numerous engravings.

Mourning pins may be made of brass, in the manner above described, varnishing being substituted for tinning; but those made of steel wire, tempered to a deep purple, are much neater as well as stronger.

PIN MONEY. Gifts by a husband to his wife for the purchase of apparel, ornaments for her person, or for her private expenditure, are called pin-money; and such gifts may either be made during marriage, or, what is the more usual case, a sum of money for that purpose may be secured by the husband to his wife by settlement, or by articles executed before the marriage. Perhaps it is only money secured before marriage for the purposes enumerated that is properly called pin-money; for a gift of money by the husband to the wife after marriage is liable to the husband's debts; but a provision for pin-money is not so liable, and the wife is entitled in all cases to such money, and to her savings out of it, and things bought with it.

Several of the questions upon pin-money have arisen after the husband's death when arrears have been claimed by the wife; and it is the general rule that she can only claim arrears of one year's pin-money if she has been supported by the husband with necessaries during the time that such arrears have accumulated, it being presumed from the fact of arrears accumulating, and her wants in the meantime being supplied, that she has waved her claim to pin-money; but she may by evidence rebut such presumption. If it is expressed in the settlement or articles that the pin-money is given for a particular purpose, as for the wife's apparel, and it is proved that the husband provided apparel for the wife, she has no claim after his death to any arrears of pin-money.

If the husband leave a legacy to the wife equal to the arrears of pin-money or more, such legacy, according to the general rule as to the satisfaction of debts by the giving of legacies, will be considered as a payment of the arrears due at the time when the will was made. If a wife elope and live apart from her husband, either in a state of adultery or not, she does not thereby forfeit her right to her pin-money, and she may recover it.

PINA. [PORTUGAL.]

PINCIA'NO. [NUNEZ.]

PINDAR, son of Daiphantus (or, as others say, of Pagondas, or Scopelinus) and Clidice, was born at Cynoscephalæ, a village between Thebes and Thespia, in Ol. 65, 3 (B.C. 518), according to Clinton (*Fasti Hellen.*, iii., p. 609), or in Ol. 64, 3 (B.C. 522), according to Böckh (Pindar, tom. iii., p. 14), and died, according to the former computation, in B.C. 439, according to the latter in B.C. 442, having completed his eightieth year. He was born at the time of the Pythian games (about the beginning of July: Arnold, Thucyd., ii., p. 418), and he speaks himself (*Fragm. incert.*, 102) of 'the festival recurring at the beginning of every five years, at which I was first laid upon the bed in swaddling clothes.' His wife was Megaclea, daughter of Lysitheus and Callina: he seems also to have been married to a woman named Timoxena: he had a son Daiphantus, and two daughters, Eumetis and Protomache.

Pindar's family were hereditary flute-players; their profession was of great reputation at Thebes, though flute-playing did not come much into fashion at Athens till after the Persian war. Accordingly he seems to have applied himself at first to that branch of poetry which was peculiarly adapted to a flute accompaniment, and his first instructor was Lasos of Hermione, a celebrated dithyrambic poet, whose favorite instrument was the flute. (Plutarch, *De Mus.*, c. 29.) But Thomas Magister, in his 'Life of Pindar,' says that his father began to teach him the flute, and finding that his capacity was of a higher order, placed him under Lasos, who initiated him into lyric poetry. It is clear however, from what we know of the style of Lasos, that he could not have had much to do with the formation of Pindar's style as a lyric poet. It is more probable that Pindar, as is expressly stated, profited chiefly by the advice and example of Corinna, the Tanagræan poetess, whose odes were of the same mythical character with those of Pindar, and who was not an imitator of the Lesbian school, but a teacher of choruses, like Pindar himself. Plutarch tells us (*De Glor. Athen.*, c. 4) that Corinna recommended Pindar to introduce mythical narratives into his odes, for that this was the proper business of the poet—the rhythm, music, and ornamented diction being only vehicles of the subject-matter; and that when, in obedience to her suggestion, the young poet composed a hymn full of Theban mythology, she remarked with a smile, that 'he ought to sow with the hand, and not with the whole sack' (*τῇ χειρὶ δεῖν σπείρειν ἀλλὰ μὴ ὅλῳ τῷ θυλάκῳ*). This Corinna frequently contended against her pupil in the musical contests, and gained five victories over him (Pausan., ix. 22; Ælian, *V.H.*, xiii. 24), though she found fault with the poetess Myrtis for doing the same thing: 'I blame the clear-toned Myrtis, I, that she, a woman born, should enter into rivalry with Pindar.' (Apollon. Dyscol., *De Pronom.*, p. 64, B.) He had another instructor, Agathocles, or Apollodorus, of Athens, who allowed him to teach the cyclic or dithyrambic chorus there, while he was a mere boy. Pindar must have commenced at a very early period his career as a professional composer of choral odes for special occasions. At the age of twenty he composed an Epinician ode in honour of Hippocles, or Hippocleas, of Pelinna in Thessaly, who had won the prize at the Pythian games; and this ode, which is still extant (*Pyth.*, x., composed in B.C. 502), exhibits no marks of a want of skill or practice on the part of the author. He soon rose to the highest rank in his profession, and spent his long life in lucrative intercourse with the tyrants and wealthy men of Greece and its colonies. The free states vied with one another in honouring the great lyric poet. He had the *προξενία*, or complimentary franchise at Athens, Ægina, and Opus; and although the people of Ceos had two celebrated poets of their own, namely, Simonides and Bacchylides, they employed Pindar to compose a *προσόδιον*, or procession-ode, for them. At Delphi he had an iron chair to sit upon when he sang the Apollinean hymns (Pausan., x., 24, sec. 4), and, by order of the Pythia, he received a portion of the banquet of the Theoxenia. (Plutarch, *De Sera Num. vindict.*, c. 13.) A long time after his death, and not, as the pseudo-Æschines states, in his lifetime, his statue was erected at Athens (*πρὸ τῆς βασιλείου στοᾶς*). He was courted by Hiero, tyrant of Syracuse; by Thero, tyrant of Agrigentum, and his brother Xenocrates; by Thrasydæus, son of Thero, and Thrasybulus, son of Xenocrates; by Arcesilaus IV., king of Cyrene; by Thorax, one of the Aleuadæ; and by Alexander, the son of Amyntas, king of Macedon, who was an active patron of lyric poetry. Pindar, as might have been expected, from the nature of his employment, was very religious, or, rather, very observant of particular superstitions. He had consecrated a temple to the Magna Mater and Pan near his own house at Thebes; this was probably in his character of hereditary flute-player, for the Magna Mater and Pan were Phrygian deities, in whose honour the first flute-music was composed. He also dedicated statues to Jupiter Ammon, and to Mercury of the Agora, and also perhaps to Apollo Boëdromius.

The entire specimens of Pindar's works which have come down to our time (with the exception of the 11th Nemean) belong to one class, that, namely, of the Epinician or triumphal odes. Besides these however Pindar wrote dithyrambs, pæans, dirges, drinking songs, mimic dancing songs (*ὑπορχήματα*), songs of maidens (*παρθένεια*), and encomia or panegyrics on princes, of all which we have numerous fragments. Horace mentions the various kinds of poetry which Pindar cultivated in the following order (*Carm.*, iv. 2):—

Seu per audaces nova dithyrambos (the cyclic chorus)
Verba devolvit—
Seu Deos regesve canit Deorum
Sanguinem (the hymns).
Sive, quos Elea domum reducit
Palma cælestes (the Epinician odes).
Flebili sponsæ juvenemve raptum
Plorat (the dirges).

From which we may infer that Pindar was not regarded by the antients as pre-eminently or exclusively a composer of Epinician odes. On the contrary, it is likely that Pindar was quite as celebrated in other departments of lyric poetry; and from his education under Lasos, and his hereditary profession of a flute-player, it is not improbable that the dithyramb, which is placed first by Horace, was his favourite style of composition. We have still a very beautiful fragment of a dithyramb by Pindar; and if the others were like it, we may well regret the loss which we have sustained. As however all Pindar's extant odes (with the one exception just mentioned, of an ode composed for the installation of a Prytanis at Tenedos) were composed for the celebration of some victory in the public games, we must be content to form our judgment of his poetical power from these specimens, and in order to this we must bear in mind the very peculiar nature of the occasion for which they were composed, for it was this which gave the ode itself the particular character by which it was distinguished. An Epinician ode was the celebration of a victory gained at one of the public games, either by the speed of horses, by strength of body, by skill in gymnastic exercises, or by proficiency in music. Along with the victor's name the herald proclaimed that of his native city, which was considered to derive great renown from the achievement of its citizen. The games themselves being a religious institution, it is obvious that the celebration of the victory must also have had something of a religious character. It was in fact a mixture of the solemnities of religious worship with the joy and revelry of the feast, a mixture very common among the Greeks, whose sacrifices to the gods were often only a constituent part of the banquet. The victor either went in procession to the altar of the god of the games, as at Olympia, in the evening of the contest, accompanied by a *comus*, which sang the *καλλίνικος* of Archilochus, or an ode composed for the occasion by some other poet; or he celebrated his victory on his return to his native city by a procession to a temple, a sacrifice, a banquet, and a comus. The poet praised both the victor himself, and his native city: the victor was praised either for his wealth (*ὄλβος*), as in the case of the horse-race, for it was only the wealthy who could contend for this prize, as Pindar himself says; or for his valour (*ἀρετή*), if he had been exposed to any danger in the contest. The city of the victor is generally praised with some reference to the mythical legends of its early history. This mythical element always formed the chief part of Pindar's ode, and it is allowed to run into every sort of digression, not however at random, but with some fixed purpose, which we have generally no difficulty in determining. Although Pindar's Epinician odes were performed by a chorus, the poet is always considered to speak in his own person. He avails himself of this, to deliver advice to the victor whose praise he is singing; to defend himself against the calumnies of his enemies; to criticise and depreciate rival poets, such as Simonides and Bacchylides; and sometimes even to address the person whom he employed as his *χοροδιδάσκαλος* when his own absence prevented him from teaching the chorus. Thus in *Olymp.* vi., v. 88, he addresses the Stymphalian Æneas, who had been sent to receive the ode, and to instruct the chorus of his countrymen in the words and music of it:—'Urge your companions, Æneas, in the first place to sing the praises of Juno, and then let them know if we really escape the old calumny, '*Bœotian swine;*' for you are a correct messenger, the estafette of the fair-haired muses, a sweet mixing-cup of loudly-uttered minstrelsy.' He often makes boastful comparisons between himself and other poets, as when he says (*Ol.*, ii., 83):—'I have many swift arrows within my quiver; they have a voice for the wise; but for the common herd they need an interpreter: wise is he who has learned much by his natural abilities; but those two (Simonides and Bacchylides), whose expertness comes from practice only, babbling in their garrulity like a brace of jack-daws, clamour in vain against the god-like bird of Jove (i.e., himself).' The most striking feature in Pindar's poetry is its picturesqueness. He has great skill and power in description, and his style abounds in the most racy and vivid metaphors. From the festal nature of most of his odes, we find in them, not unfrequently, coarse jocularities which are repugnant to the spirit of modern lyric poetry, and which therefore offend the modern reader, who comes to the perusal of Pindar with vague expectations of that continued flow of sublime imagery and dignified but pompous diction which are generally considered essential to the lyrical poem. It should never be forgotten, that though the occasions for which Pindar wrote required much of solemnity and religious gravity, they admitted, at the same time, every variety of jocose merriment which such a joyful event might suggest. In a word, the Epinician odes of Pindar were performed by the comus as much as by the chorus; they were sung to the loud-booming flute as much as to the tranquil melodies of the harp; and the rhythms were Æolian, or Lydian, as often as Doric.

The best edition of Pindar is that by August. Böckh, Lipsiæ, 1811, 1821, 3 vols. 4to. The sound criticism which Böckh has applied to the text of the author, and his comprehensive and masterly explanations, have thrown an entirely new light upon the music, metres, lyric poetry, &c. of the Greeks. Ludolf Dissen, who wrote the explanations to the Nemean and Isthmian odes for Böckh's edition, subsequently (1830) published a smaller edition, which may be considered as an abridgment of Böckh's. As an explanatory edition it is a very good one; but as the fragments are not printed complete, it cannot be considered as a substitute for its predecessor. There is a very good translation of Pindar into English verse by the Rev. H. F. Cary (London, 1833), which would have been still better if the translator had taken Böckh and Dissen for his guide instead of Heyne. The translations by West and Moore are very inferior to Cary's, as representatives of the sense of the original, though there is much of taste and vigour in those of the latter author.

PINDEMO'NTE, IPPO'LITO, born at Verona, in 1753, was a younger son of a patrician family of Verona. His elder brother, Giovanni Pindemonte, wrote some tragedies, among others, 'I Baccanali,' which were much esteemed at the time. Ippolito studied at the college of Este, and afterwards at Modena. On completing his studies, he travelled through Europe, and visited France, Germany, Holland, and England, of which last country he speaks in his verses with affectionate remembrance. Being made a knight of the order of St. John, he went to Malta, where he resided some time, as well as in Sicily. When he was about thirty years of age, a serious illness, which showed the constitutional weakness of his frame, induced him to give up active life and retire to the country. He fixed his residence at Avesa near Verona, where he wrote his 'Prose e Poesie Campestri,' published first in 1785, and often reprinted since. The philosophy of his prose is of the contemplative kind, but it is warm-hearted and liberal. His poetry is beautifully harmonious and flowing. In his next production, 'Epistole in Versi,' he alludes to the revolutionary war then raging in Italy, and its fatal effects upon morals and social happiness. The catastrophe of Venice is especially deplored by him, as well as the devastation of his own native town, Verona, in 1797, and the plunder of the Italian works of art, which were carried to Paris. These passages from the pen of an upright independent man are instructive comments upon the true character of those times. Pindemonte afterwards published a volume of Sermoni, also in verse, being a kind of satires after the manner of Horace, in which he lashes, though in a good-humoured strain, the follies of his age. In one of these compositions, entitled 'I Viaggi,' he ridicules the affectation of his countrymen, who, after having visited France, England, or Germany, returned full of disdain for their native country, and were continually boasting the superiority of foreign manners, foreign luxuries, and even foreign vices. He then passes in review the foreign travellers who visit Italy, exhibiting their national peculiarities, their fault-finding with the inns, the roads, the carriages, the manners, society, everything in short, and regretting that they cannot find in the Italian cities the sprightly gaieties of Paris or the domestic comforts of England. He pourtrays the German, with his bulky album, writing his memoranda at every stage; the Spanish grandee, with his golden fleece hanging on his breast, visiting every church or convent on his way, pompous, listless, and taciturn; the Russian, priding himself on his French and his knowledge of the arts. In another Sermone, entitled 'Le Opinioni Politiche,' the author takes for his text Goldsmith's lines—

> 'In ev'ry government, though terrors reign,

'I also,' says Pindemonte, 'can distinguish between the civil institutions of various countries; I can discern the gold from the dross; I know the difference between England and Turkey; but what I blame is the exclusive importance attached by individuals to political opinions and political systems, as if man could not live and be happy, and make himself useful under every orderly form of government.' And in a later composition, 'Il Colpo di Martello,' he further explains his meaning in reply to some strictures of an Italian journalist: 'I never meant that the political institutions of a country do not affect the happiness of a nation; but what I said, and what I shall always repeat to foreigners as well as to my own countrymen, is, that in all countries, and under every climate, man must look for happiness within himself, and that institutions and forms of society may assist and increase his welfare and contentment, but cannot originate it.'

Pindemonte wrote a drama, 'Arminio,' in which he introduced the chorus, a novelty on the Italian stage. He published together with it, three dissertations, one on recitation, another on tragical poetry, and the third on the drama of Merope, a subject treated by both Voltaire and Maffei. These dissertations contain much sound criticism. He also published a translation of the 'Odyssey,' in Italian blank verse, which was well received. When Foscolo published his beautiful little poem the 'Sepolcri,' addressed to Pindemonte, the latter replied to it by another poem on the same subject, which is full of pathos, and at the same time of consolatory thoughts on man's immortality. The two poems are generally published together.

The last work of Pindemonte was his 'Elogi di Letterati,' a biographical work in prose, 2 vols. 8vo., 1825-6. Pindemonte's health had always been delicate, and in his latter years he suffered from depression of spirits, which the death of his early friends, and especially of Foscolo and Monti, seems to have increased. He died at Verona, in November, 1828, a month after the death of Monti. His unblemished character, his amiable disposition, and his great accomplishments, contributed as much as his writings to mark him as one of the most distinguished Italians of his age. A monument has been raised to his memory by his townsmen of Verona.

PINDUS. [GREECE.]

PINE-APPLE, the fruit of the *Ananassa sativa*, Lindl., a tropical plant, indigenous to South America and some of the West India Islands. It has become so perfectly naturalised in many parts of the hot regions of Asia and Africa, that it has been thought to be likewise a native of those countries. When the British troops invaded Burma, they found the woods around Rangoon abounding in wild pine-apples, and a variety from the back of the Black Pagoda was in great request for its excellence: in the Malay Archipelago it acquires an enormous size, and sports into a variety called *the double pine-apple*, each pip of its fruit growing into a branch bearing a new pine-apple. It was however first introduced into Europe from South America, and, as it is recorded by M. Le Cour of Leyden, about the middle of the seventeenth century: from Holland it was brought to this country in 1690, by the earl of Portland, according to the Sloanean MSS. in the British Museum. There is a painting, formerly in the collection of Horace Walpole, in which Charles II. is represented as being presented with the *first* pine-apple by Rose, his gardener; but there are some doubts whether that fruit was grown in England or obtained from Holland. It may however be fairly concluded that pine-apples were exceedingly rare in this country, even at the tables of the nobility, in the beginning of the last century; for in 1716, Lady Mary Wortley Montagu remarks that pine-apples were on the electoral table at Hanover when she was there in that year, on her journey to Constantinople; and she states that she had never previously seen that species of fruit. (*Letters of Lady M. W. Montagu.*) Since that period the cultivation of the pine-apple has been prosecuted with perseverance in Britain, but frequently the results have been very disproportionate to the expense incurred. Within the last twenty years however, success has been more general; and in many instances a surprising degree of perfection has been attained, much greater indeed in England than in any other country having to contend with an extra-tropical climate, for instances are on record of pine-apples weighing 13lbs. and 14lbs. avoirdupois, and from 7lbs. to 8lbs. is by no means an uncommon weight for a single fruit. At the present day the pine-apple in England is so abundantly produced, that although expensive, it is very common. Its delicious flavour, and the noble appearance which a well-grown fruit exhibits, render the cultivation of it a special object of horticultural enterprise and skill.

As, notwithstanding the many treatises that have been written on the subject, failures in the production of fine fruit continue to occur, it seems desirable to point out in what the mismanagement of a gardener is most likely to consist, and how he may apply the directions to be found in books of gardening with least chance of failure.

It has been already stated that this plant is an inhabitant of the tropics, and it may be added, near the level of the sea. The latter circumstance it is necessary to remark, because if it were a mountain plant, even though tropical, it might be natural for it to endure a comparatively low degree of temperature. But according to Beyrich (*Gardener's Magazine*, iii. 442), 'the pine-apple in its wild state is found near the sea-shore, the sand accumulated there in downs serving for its growth, as well as for that of most of the species of the same family. The place where the best pine-apples are cultivated is of a similar nature. In the sandy plains of Praya Velha and Praya Grande, formed by the receding of the sea, and in which no other plant will thrive, are the spots where the pine-apple grows best.' The temperature at the level of the sea at or near the equator varies but little throughout the year; for instance, the mean temperature of the warmest month at Cumana, 10° 27′ N. lat., is, according to Humboldt, 84·38°, and that of the coldest 79·16°. At Havanna, on the skirt of the tropics, the mean of the warmest month is 83·84°; that of the coldest 69·98°. At Vera Cruz the mean temperatures of the warmest and coldest months are respectively 81·86° and 71·06°.

In conformity with the above, and also from the results of experience, it may be stated that the artificial temperature of the atmosphere in which the pine-apple is intended to be grown should have a mean of about 80°; or a minimum not lower than 70° at any time of the year, and a maximum not higher than 90°. When, from the shortness of our days in winter, there is a deficiency of light, and when forcing the plant in its absence would produce only imperfectly formed tissue, 70° will be proper. In summer 80° to 85°, or in the case of fruiting plants, from that to 90° will not be too much. The maximum by sun-heat may extend higher, but 100° should be its limit.

With regard to bottom-heat, it should be in imitation of the heat of the tropical soil; and this varies even less than the temperature of a tropical atmosphere. The mean temperature of the earth is generally supposed to be somewhat higher than the mean of the atmosphere, owing to the greater capacity of the soil for retaining caloric. The discrepancy however cannot be great; and if the mean atmospheric temperature at the equator be from 80° to 84°, as has been ascertained from numerous observations, the temperature of the soil, it may be presumed, will not average lower; nor will it be many degrees higher where moisture sufficient for vegetation exists, as is generally the case in islands; although on continents it becomes so great as to reduce the soil to a desert. The temperature of the earth a foot below the surface, in New Granada, is 85° during summer, according to a correspondent of Mr. Hay (*Gard. Mag.*), and this degree of heat will be found a very good medium for the roots of the pine-apple. Bottom-heat then should never be allowed to fall below 75°, nor rise higher than 90°.

The soil for pine-apples requires to be rich. A fresh yellow loam, strong, but by no means of a binding nature, with which is mixed a quantity of cow-dung, will answer very well. The pots require to be well drained, and over the drainage some pieces of turf may be placed. Manure-water, made by steeping sheep's dung or cow-dung, is occasionally applied, care being taken that it be properly diluted. If the plants are found not to be thriving, they may be shifted, without hesitation, at any period of their growth.

It is very important that a perfect drainage be at all times maintained. When pots are plunged in tan, the worms are apt to close the holes in the bottom of the pots by their excretions; or a stoppage may occur in consequence of the pressure of the pot upon the tan when it wastes and becomes capable of being rendered compact. From whatever cause the defect proceeds, a good preventive may be easily effected by simply plunging an empty pot, with its *mouth downwards*, and on this placing the bottom of that containing the plant, closing the tan round the sides of the latter in the usual way. If at any time the tan should become too hot, it may be partially removed from the sides of the pot.

Moisture is essential for the growth of the pine-apple. The condition of the soil in the pots will of course indicate whether water should be applied or withheld. But in summer the atmosphere should be kept moist by syringing, particularly before shutting up at night. No water should on any account be used of a temperature many degrees lower than that of the soil in the pots where the plants are growing; it should not, in short, be applied lower than 75°, and 80° will prove a good medium. When the fruit is ripening off, moisture of course should be withheld; and in damp cloudy weather in winter, when it is an object to restrain rather than promote growth, they should be kept rather dry than otherwise. Moisture will not prove injurious when it is accompanied by a sufficiently high temperature and a due share of light. The mode of heating by means of hot-water pipes is undoubtedly the best for pine-stoves; and steam from the boiler should be at command, so that it may be introduced to the interior of the house as occasion requires.

Pine-apples may be grown under various modes of treatment. Instead of being confined in pots, they are sometimes planted in a bed of soil. This has been found to answer very well where good drainage was secured, and where a proper degree of bottom-heat could be applied. They have also been grown in pots placed on shelves or on sand; this mode however has not proved fully successful, for the roots are subjected to vicissitudes consequent not only upon the variations in the temperature of the atmosphere of the house, but also its hygrometrical conditions.

A principal cause of failure in the cultivation of the pine-apple appears to have arisen from the idea that the plants will bear a much lower degree of temperature than that above pointed out as being natural to them. They will *apparently* do so; but although the plants may continue to have a healthy appearance, yet experience proves that their vital energy is interfered with, and their powers of organization diminished, as is continually indicated by the fruit-stem being sent up with only a few imperfect pips. The stagnation of water about the roots from defect of drainage, too much heat and moisture, or too much heat and dryness, or checking the plants by cold in order to bring them to a fruiting condition, instead of forwarding them naturally to that state, are other sources of failure on the part of cultivators. With regard to the last, the only method that ought to be taken to bring on the time of fruiting is to inspissate the sap, and to augment the amount of secretions by gradually withholding moisture and increasing the temperature, at the same time admitting a little more air than usual; and after this, by the sudden application of a brisk temperature with more moisture.

To richly manured soil the large size of the pine-apples produced in England may be attributed; and to the means that cultivation under glass affords of progressively inspissating the juices towards the period of ripening, may be ascribed the superiority of the fruit to that produced in countries where the plants are indigenous, as was alluded to under Ananassa sativa.

The varieties of the pine-apple are numerous; the best however have been already enumerated [Fruits]; and full descriptions of upwards of fifty varieties may be referred to in the *Trans. Hort. Soc. of London*, 2nd series, vol. i.; and of all the principal varieties in the *Guide to the Orchard and Kitchen-Garden*.

PINE TREE. [Pinus.]

PINEAL GLAND. [Brain.]

PINE'DA, JUAN DE, born at Seville, in 1557, entered the order of St. Francis, and not of the Jesuits, as stated in the 'Biographie Universelle.' He acquired a great reputation for general erudition, especially in the Greek, Hebrew, and Oriental languages. On being appointed counsellor to the court of the Inquisition, he was commissioned to visit the principal libraries of Spain, in order to register those works which might be obnoxious to the Roman Catholic religion. The result of his inquiry was an 'Index novus Librorum Prohibitorum,' Seville, 1631, published by order of Cardinal Zapata, grand-inquisitor of Spain. Pineda published a version of Theodore Peltar's 'Catena Græcorum Patrum in Proverbia Salomonis.' He also published — 1, 'Commentarius in Job,' 2 vols. fol., Madrid, 1597; 2, 'Salomo Prævius, sive de Rebus Salomonis Regis,' libri octo, Lyon, 1609; 3, 'Commentarius in Ecclesiasten,' Antwerp, 1620; 4, 'Monarchia Ecclesiastica, o Historia Universal del Mundo desde su Creacion hasta estos Tiempos,' 5 vols. fol., Barcelona, 1620. This work is a universal history of the world in 30 books, and is written with some display of erudition but no discrimination, and with all the intolerant spirit of an inquisitor. It seems that the Spaniards had no universal history in their language, and Pineda undertook to supply the deficiency.

PINERO'LO. [Pignerol.]

PINGRE', ALEXANDER WILLIAM, was born at

Paris, 4th of September, 1711, and educated in a religious establishment at Senlis. At the age of twenty-four he was appointed professor of theology, but during the persecution of the Jansenists he was deprived of his situation by the government, for some years after which he gained a livelihood by teaching the elements of grammar in an obscure college. Disgusted with his theological career, at the age of thirty-eight years or thereabouts, he began the study of astronomy, and his friend Lecat, a celebrated physician of his day, having shortly afterwards founded an academy at Rouen, the department of astronomy in that establishment was placed under Pingré's direction. His observation of the transit of Mercury, on the 6th of May, 1753, led to his being nominated a correspondent of the Academy of Sciences, of which, in 1756, he was elected a free associate. About this time also he was appointed chancellor of the university of Paris, and librarian of the abbey of Sainte Geneviève, on the summit of which building a small observatory was erected for his use. In connection with Lemonnier he computed a nautical almanac, called the 'Etat du Ciel,' for the the years 1754-7. In this work his chief object was to render an essential service to the mariner by supplying the means of determining a ship's longitude, which he proposed to deduce from the moon's hour angle by the aid of tables computed by himself with very great labour. The method however inspired little confidence, and was shortly afterwards superseded by one suggested by Lacaille, and now in general use, in which the longitude is deduced from the observed distance of the moon from a known star or planet.

In 1760 Pingré, by order of the government, sailed for the island of Rodrigo, in the Indian sea, in order to observe the transit of Venus, which took place on the 6th of June of the ensuing year. The ultimate object was the determination of the sun's parallax, which Pingré, from his own observations, inferred to be about 10″, but in later years his calculation was found erroneous. The same phenomenon was observed by him at the island of St. Domingo in 1769, during one of four voyages undertaken by him to try the chronometers of Berthaud and Leroy.

He died at Paris, 1st of May, 1796. The memoirs contributed by him to the Transactions of the Academy of Sciences consist chiefly of accounts of his observations, and will be found between the years 1753 and 1770. Of his published works the only one to which the least interest is now attached is his 'Cométographie, or an Historical and Theoretical Treatise on Comets,' Paris, 1783, 2 vols. 4to. Besides a very complete account of all that was then known concerning the nature and motions of comets, it contains the elements of no less than eighty orbits computed by himself. The readiness with which he engaged in the most lengthy numerical calculations appears to have been the most prominent point in his character. Lacaille had computed, for the 'Art de vérifier les Dates,' a table of the eclipses visible in Europe during the first eighteen centuries of the Christian æra. Pingré, without any obvious motive, repeated the whole of the working, adding however a list of the eclipses during the ten centuries preceding. He had also reduced a very large number of observations of different astronomers, beginning with Tycho Brahé, for a work which he intended to call the 'History of Astronomy during the Seventeenth Century.' Several sheets of the work were printed, when further progress was suspended by the depreciation of the assignats, and the publication has not since been, nor is it likely to be, resumed.

(Delambre, *Biographie Univ.*; *Mémoires of the French Institute*, 1790; *Notice of Pingré*, by M..Prony.)

PINIC ACID. This acid is obtained, according to Unverdorben, by digesting colophony, or common rosin, in cold alcohol of specific gravity 0·833. The solution obtained is to be mixed with one of acetate of copper in alcohol, and there is then precipitated a combination of oxide of copper with pinic acid; this salt, after washing with alcohol and digestion in a mixture of alcohol and hydrochloric acid, yields a solution from which water throws down pinic acid. The pinates of ammonia, potash, and soda are soluble in water, but those of other bases are mostly insoluble in it; they are generally dissolved by æther, but not by alcohol. When pinic acid is washed and boiled in water, it forms on cooling a hard brittle substance, which becomes brown by fusing, and passes into what Unverdorben calls colophonic acid.

PINITE, a mineral which occurs in imbedded crystals. Primary form a rhomboid, but generally found in hexagonal prisms. Cleavage parallel to the lateral faces of the prism. Fracture indistinct, uneven. Hardness, scratches gypsum, is scratched by fluor spar. Colour reddish, greyish, and greyish-red. Lustre slightly resinous. Opaque. Specific gravity 2·78 to 2·98.

Before the blow-pipe on charcoal it whitens, fuses on the edges, and yields a white glass with bubbles; with borax it fuses with difficulty into a transparent glass, coloured by iron. The Saxon variety is infusible.

It is found in Saxony, France, England, in some other parts of Europe, and in North America.

According to Gmelin, the pinite of St. Pardoux in France consists of—silica, 55·964; alumina, 25·480; potash, 7·894; soda, 0·386; peroxide of iron, 5·512; magnesia with manganese, 3·760; water with animal matter, 1·410: total, 100·406

PINK. [CARNATION.]

PINKERTON, JOHN, was born at Edinburgh in 1758, and was the third and youngest son of James Pinkerton. After finishing his school education, he was articled to a writer to the signet, in whose office he spent five years; but it does not appear that he ever engaged in the practice of that or any other profession. He commenced author in 1776, by the publication of an elegy entitled 'Craigmillar Castle;' and on the death of his father in 1780 he came to London, and settling there gave himself up to a literary life. In 1781 he published an octavo volume of poetical pieces under the title of 'Rimes,' which reached a second edition; and this was followed the same year by the first edition of a less forgotten publication, an octavo volume entitled 'Scotish Tragic Ballads,' a second edition of which appeared in 1783, accompanied with a second part containing 'Ballads of the Comic Kind,' the whole being now included under the general title of 'Select Scotish Ballads.' Of these pretended antient ballads however a considerable number were fabrications of Pinkerton's own. Meanwhile in 1782 he had published 'Two Dithyrambic Odes on Enthusiasm and Laughter,' in a sixpenny quarto pamphlet, and soon after another original volume of the same form, entitled 'Tales in Verse.' In 1784 he produced his 'Essay on Medals,' in 2 vols. 8vo., a work of considerable merit for the time, though now of little use, but in which Pinkerton is stated to have been much indebted to the assistance of the late Mr. Douce and another friend. It has been twice reprinted since with improvements. In 1785 he gave to the world, under the *nom de guerre* of Robert Heron, an octavo volume of 'Letters on Literature,' in which some singular opinions on the value of the Greek and Roman writers were attempted to be made still more startling by a new and very strange system of spelling, in which however the inventor had the good sense not to persevere after it had answered its temporary purpose. This book procured Pinkerton the acquaintance of Horace Walpole, and through him of Gibbon and other distinguished literary characters. His next publication was one which has retained its interest and value, his 'Antient Scotish Poems, never before in print, from the MS. collections of Sir Richard Maitland of Lethington, Knight,' 2 vols. 8vo., London, 1786. It is a mistake to describe this work as a literary forgery, as has sometimes been done; the poems from the Maitland and Bannatyne MSS., of which it consists, are all genuine. [MAITLAND, SIR RICHARD.] It is here however, in a 'List of all the Scotish Poets, with brief Remarks,' that he makes his confession of the forgery of several pieces in the previous collection. When he prepared that former work, he says, he was only eighteen (for it remained five years in MS., it seems, before it was published): 'as for his secret,' he continues, 'he has observed the Horatian precept he at first laid down to himself, *nonum prematur in annum*; and requests pardon both of his friends and the public for keeping it to himself. The fiction, as the publisher can inform, could not possibly have any sordid view, as the MS. was presented to him, and one half of the future profits, which was offered, was refused. For the imposition, it was only meant to give pleasure to the public; and no vanity could be served where the name was unknown. As to the vanity or pleasure of imposing on others, if there be such ideas, they are quite unknown to the editor. Perhaps, like a very young man, as he was, he had pushed one or two points of the deception a little too far; but he always thought that novel and poetry had no bounds of fiction.' What has been called the cool impudence of this ingenuous avowal has perhaps called forth more indignation than it deserves from some of the many quarters where Pinkerton has made himself an object of aversion by certain peculiarities of his writings and character.

In 1787, besides a compilation in 2 vols. 12mo., entitled 'The Treasury of Wit,' which he published under the name of Bennet, he produced the first edition of his 'Dissertation on the Origin and Progress of the Scythians or Goths,' 8vo., a work which, whatever may be thought of some of the conclusions at which he arrives, is full both of ingenuity and of various and accurate learning, and must be admitted to be a most creditable performance for a young man under thirty. Here he first announced that strong anti-Celtic feeling which colours all his historical and antiquarian disquisitions, and which made him so many enemies. This publication was followed in 1789 by a collection of 'Lives of Scottish Saints,' in Latin, 8vo.; an edition of Barbour's poem of 'The Bruce,' 3 vols. 8vo.; and by one of his most important works, 'An Enquiry into the History of Scotland, preceding the reign of Malcolm III.,' 2 vols. 8vo. (with the Dissertation on the Goths appended). This inquiry (which was reprinted, along with the Dissertation, in 1794, and again in 1814), with all the perversity or want of judgment on some points by which it may be thought to be disfigured, is still one of the ablest and most valuable works we possess on the subjects to which it relates, and would be indispensable to the student of Scottish antiquities, were it only for the many curious documents it contains, all rare, and some of them nowhere else to be found in a printed form. It was succeeded by 'The Medallic History of England, to the Revolution,' 4to., 1790; 'Scotish Poems,' reprinted from scarce editions, 3 vols. 8vo., 1792; 'Iconographia Scotica, or Portraits of Illustrious Persons of Scotland, with Biographical Notes,' 2 vols. 8vo., 1795-1797; and 'The History of Scotland, from the Accession of the House of Stuart to that of Mary,' 2 vols. 4to., 1797, another work of original research and great importance, although most repulsively written, from an unfortunate fancy of imitating Gibbon which had taken possession of the author, to the destruction of his own natural style, which, if not in other respects very happy, was at least plain and unaffected, and occasionally not without considerable vigour and liveliness. Prefixed to this work is a portrait of the author, with spectacles on, and surrounded by his books, with an inscription which takes care to inform us that he was as yet only in his thirty-eighth year. And he was certainly entitled to take to himself the credit of a most respectable amount of literary performance for that age. After the death of his friend the Earl of Orford, in 1797, Pinkerton communicated notes of his conversation in a series of papers to the 'Monthly Magazine,' which he afterwards collected and published along with a memoir of Walpole, in 2 vols. 12mo., under the title of 'Walpoliana.' His next publication was 'The Scottish Gallery, or Portraits of Eminent Persons of Scotland, with their Characters,' 8vo., 1799. In 1802 appeared the first edition of his 'Modern Geography, digested on a new plan,' in 2 vols. 4to., a second edition of which, extending to 3 vols., was brought out in 1807. There is also an abridgement of this work, in 1 vol. 8vo. In 1802 Pinkerton left England, and for the rest of his life resided chiefly in Paris, continuing however to give occupation to the press of his native country with his usual industry. Two thick but not very well filled octavos, entitled 'Recollections of Paris in the Years 1802-3-4-5,' which he published at London in 1806, exposed him to much ridicule by the Frenchified style of thinking and air of *petit-maitreship* affected by the quondam laborious antiquary. Returning however to his proper beat, he commenced in 1808 his great 'General Collection of Voyages and Travels,' which was completed in 16 vols. 4to., in 1813. This was accompanied by a 'New Modern Atlas,' published in parts, which was begun in 1809 and finished in 1815; and while occupied with these compilations he also found time to write his 'Petralogy, or a Treatise on Rocks,' which appeared in 2 vols. 8vo., in 1811, and was his last original work. He died at Paris, on the 10th of March, 1826, leaving a widow, a sister of Dr. Burgess, the late bishop of Salisbury, from whom however he had been separated for many years. The above detail of his literary labours is evidence sufficient that Pinkerton was no ordinary man; and his best performances, such as his Dissertation, his Enquiry, his History, and his edition of the Maitland Poems, with all their faults, not only all overflow with curious learning and research, but bear upon them the impression of a vigorous, an ingenious, and even an original mind. His violence and dogmatism, his arrogance and self-conceit, his pugnacity and contempt for all who dissented from his views, and above all his shallow and petulant attacks upon the common creed in religion and morals, have raised a general prejudice against Pinkerton, which has prevented justice being done to his acquirements and talents, and the real value of much that he has written. Two octavo volumes of his correspondence were published in 1830, the contents of which however are not of much interest.

PINNA MARI'NA. [MYTILIDÆ, vol. xvi., p. 50.]

PINNOTHE'RES. [PINNOTHERIANS.]

PINNOTHE'RIANS, a tribe of the third family of the *Brachyurous Crustaceans* (*Catametopes*), according to the arrangement of M. Milne Edwards.

The *Pinnotherians* are small crustaceans whose *carapace* is nearly circular, and whose teguments exhibit considerable softness. Their *eyes* are in general very small, and the disposition of their *front* and their *antennæ* varies, as also their *external jaw-feet*, which present remarkable anomalies. Their *feet* are short or of moderate length, and are in general very weak. The *abdomen* of the male is much narrower at its base than the corresponding part of the sternal plastron.

But it is the singular habits of these crustaceans which especially demand attention; for they ordinarily are housed between the mantle-lobes of certain conchifers—*Mytilus*, *Pinna*, *Mactra*, &c., for example.

M. Milne Edwards arranges in this small group the genera *Pinnotheres*, *Doto*, *Mictyris*, *Hymenosoma*, and *Elamena*; but he acknowledges that this tribe is not so natural as might be desired, and that hereafter perhaps the necessity for subdividing it may arise.

Pinnotheres. (Latreille.)

Generic Character.—*Body* circular and rounded above; front not soldered to the epistome; *eyes* very small, *orbits* nearly circular; internal antennæ of the ordinary form, and the fossets which lodge them scarcely separated from each other; *external antennæ* short, occupying the internal angle of the orbit. *Buccal* frame very wide backwards, and describing a semicircle forwards. *External jaw-feet* placed very obliquely; their enlarged and valvular portion is formed entirely by their third joint, which is very large, whilst the second is rudimentary; the fourth joint is inserted at the summit of the preceding, and the fifth, which is tolerably developed, is articulated with the sixth by the middle of its internal border, so that it is placed nearly like the thumb of the didactylous claws. The *sternal plastron* is very wide, and, in the male, the apertures of the organs of generation occupy its last segment. The *feet* are moderate. The *abdomen* of the male is small, whilst that of the female is ordinarily very convex, and much larger than the sternal plastron. (Milne Edwards.)

View of the under side of the upper part of Pinnotheres, eyes, jaw-feet, &c seen from below and magnified. (M. Edwards.)

Before we lay before our readers examples of this curious crustacean, it is necessary to refer them to Mr. Thompson's interesting 'Memoir on the Metamorphoses and Natural History of the Pea Crab' (*Entom. Mag.*, No. xi.), whence it appears that *Pinnotheres*, in the early stages of its existence, has a very elongated abdomen which is terminated by a fin, the carapace armed with three spiniform prolongations, very large eyes and natatory feet; in short that it then bears the greatest resemblance to *Zoea*.

These curious animals were known to the antients, who were not ignorant of their connexion with the *Pinnæ*. The Greeks named them Πιννοτῆρας (Pinnoteres) and Πιννοφύλαξ (Pinnophylax). (Arist., *Hist. Anim.*, v., xv.) Oppian (*Halieut.*, ii., line 186, et seq.) treats the connexion as a sort of partnership for obtaining prey. The *Pinnoteres* of Pliny (*Nat. Hist.*, ix., xxxi.) described as harbouring in the empty shells of oysters, and as migrating to others when it increased in growth, appears to have been more applicable to the *Pagurus* of the moderns; but the same author, in the forty-second chapter of the same book, 'De Pinna, et Pinnotere, et aquatilium sensu,' uses the terms *Pinnoteres* and *Pinnophylax* to designate the crab which resides in the shell of the *Pinna*.

Among the moderns Hasselquist has given one of the best accounts of the habits of the genus. In a letter to Linnæus, dated 'Smyrna, December 16, 1749,' he says, 'The time I have been here has afforded me an opportunity of seeing the kinds of fish and shell-fish the Greeks use in their Lent. I believe no people make so much use of shell-fish and other sea animals as the Greeks do. I have seen them eat ten different sorts of shell-fish (crabs, prawns, and shrimps are not included, being ranked by Linnæus under the class of insects), when with us oysters only are eaten. Amongst others they sell here a *Sepia* (Cuttle-fish), which by them is called ὀκτωπόδια; it has only eight tentacula, all of equal length; the whole animal is a foot long, and thick in proportion. Of this the Greeks have related to me an anecdote, which I think remarkable. The *Pinna muricata*, or great Silk muscle, is here found in the bottom of the sea in large quantities, being a foot long. The ὀκτρωπόδια, or cuttle-fish with eight arms, watches the opportunity, when the muscle opens her shell, to creep in it and devour her; but a little crab, which has scarcely any shell, or has at least only a very thin one, lodges constantly in this shell-fish; she pays a good rent by saving the life of her landlady, for she keeps a constant look out through the aperture of the shell, and on seeing the enemy approach, she begins to stir, when the πίνα (for so the Greeks call the shell) shuts up her house, and the rapacious animal is excluded. I saw this shell-fish first at the island of Milo, and found such a little crab in all I opened: I wondered not a little what was her business there; but when I came here, I was first informed of it by the secretary of our consul, Mr. Justi, a curious and ingenious man, who has travelled much, and lived long in this place. This was afterwards confirmed by several Greeks, who daily catch and eat both these animals.'

M. Milne Edwards remarks that the distinction of the species of this genus is difficult, inasmuch as that the principal differences to be remarked in the greater part of them do not exist in both sexes, and are often of the nature of those which are modified by age.

We select as examples *Pinnotheres Pisum, the Pea-crab*, and *Pinnotheres veterum*, *Pinnotheres* of the antients.

Description of *Pinnotheres Pisum.*

Carapace soft; front projecting in the male, not reaching beyond the curved line formed by the anterior part of the carapace in the female. Inferior border of the hands ciliated. Abdomen of the female circular; that of the male having the last joint less than the penultimate. Length: *female*, 4 lines; *male*, 2 lines.

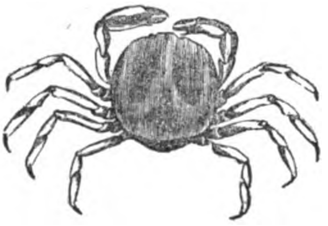
Locality.—Very common in *Mytilus edulis* on the coasts of England and France. [Leach, *Malac. Brit.*, t. 14, f. 2, 3 (female); *P. varians* of the same work, t. 14, f. 10 and 11 (male); *P. Latreillii* of the same work, t. 14, f. 7 and 8 (young female).] (M. Edwards.)

M. Milne Edwards is of opinion that *Pinnotheres Cranchii*, Leach (*Malac.*, t. 14, f. 4, 5), does not differ specifically from *Pinnotheres Pisum.*

Description of *Pinnotheres veterum.*

General form the same as in the preceding species. A small spine on the lower border of the right *manus* in the female. The abdomen of the female is oval; but this particularity may disappear with age. Length of the female, 8 lines.

Locality.—Found in *Pinnæ* on the coasts of Italy, &c.



Pinnotheres veterum.

Elamena. (M. Edwards.)

Founded on *Hymenosoma Mathæi*, figured by M. Rüppell, in his work on the 'Crustacea of the Red Sea,' and separated from that genus by M. Milne Edwards, who thinks that it seems to establish the passage between the *Hymenosomata*, the *Oxystomes*, and the *Oxyrhynchs.*

Carapace nearly triangular, plain above, and extremely flattened. The whole body nearly lamellar. *Front* large, very much advanced, and assuming the form of a small lamellar nearly-horizontal rostrum, below which the eyes are hidden; these last organs are of moderate size and not lodged in orbitary cavities; they are free under the front and are applied backwards against a small projection of the pterygostomian region. The *internal antennæ* are separated from each other by a small vertical plate of the lower surface of the front; their basilary joint is very small, and their moveable stem bends back longitudinally, and thus reaches beyond the ocular peduncles. The *external antennæ* are very small, and cylindrical from their base; they spring below the ocular peduncles, and do not reach the edge of the front. The *epistome*, instead of being hardly distinct, as in the *Hymenosomata*, is very large and nearly square. The *buccal frame* is small, quadrilateral, and entirely occupied by the *external jaw-feet*, whose third joint is nearly square, and is truncated at its anterior and internal angle, for the insertion of the succeeding joint, which is completely exposed. The *sternal plastron* is much wider than it is long. The feet are all slender, filiform, and long; those of the first pair are terminated by pincers, which are convex at the end and hollowed out into a spoon-shape; the succeeding feet end in a lamellar and slightly falciform joint. The abdomen of the female is very large. (M. Edwards.)

M. Milne Edwards is of opinion that this crustacean is nearly allied to the *Inachoïdeans*, and ought probably to be approximated to them; but not having had an opportunity of examining a male individual, and being consequently ignorant of the disposition of the male intromittent organs, he has preferred leaving it provisionally next to the *Hymenosomata*, of which it has hitherto formed a part.

Example, *Elamena Mathæi* (Rüppell, *Krabben*, pl. v., f. 1).

Description.—Carapace smooth, very wide behind, rounded on the sides, and gradually narrowed up to the rostrum, which is a little elevated; its edges furnished with a kind of horizontal crest, which is extremely delicate, and irregularly cut off as it were. Second pair of feet longest, being nearly thrice the length of the carapace. Length four lines.

Localities.—The Isle of France and the Red Sea.

Hymenosoma. (Leach.)

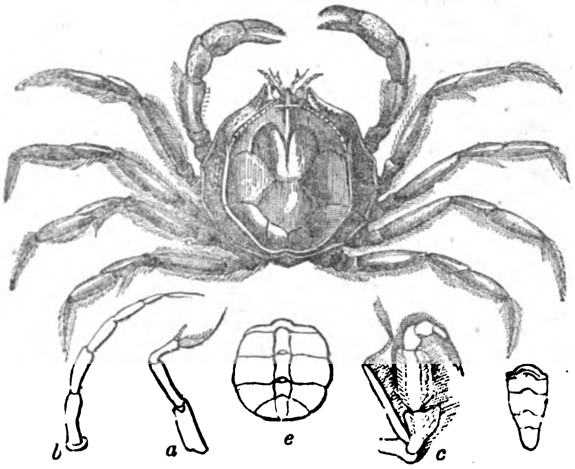
Generic Character.—*Carapace* very much flattened above, and nearly circular; the *front* very narrow and inclined. *Orbits* very small, and nearly circular, and the eyes must be bent back downwards rather than outwards to be hidden in them. The *antennary fossets* are longitudinal, and continued without interruption with the orbits; the stem of the *internal antennæ* is large. The *external antennæ* are inserted near the external angle of the orbit, and are more elongated than in the greater part of the *Brachyura*. The epistome is hardly distinct, and is hidden by the *jaw-feet*. The *buccal frame* has the form of a long square; its lateral borders are very projecting, and terminate at the exterior angle of the orbits. The *external jaw-feet* are long and narrow; their third joint is much longer than the second, and carries the succeeding joint at its anterior extremity. The *sternal plastron* is circular. The *anterior feet* are moderate, and the third pair are the longest; the tarsi are slender and styliform. The abdomen of the male is very small, only reaching to the level of the third pair of feet. (M. Edwards.)

M. Milne Edwards remarks that hitherto this genus has been arranged in the neighbourhood of the *Inachi*, principally on account of its narrow and pointed front; but its natural position appears to him to be in the family of the *Catametopes*, for it is to this type that it approaches in all the important points of its organization. Moreover, as in the greater part of the crustaceans, the abdomen of the male is much narrower than the posterior border of the sternal plastron, and the apertures of the generative apparatus are formed in that buckler, instead of being situated, as ordinarily, on the basilary joint of the posterior feet.

Example, *Hymenosoma orbiculare.*

Description.—Carapace marked above with a large circular and smooth impression; slightly granular on the sides. Two spiniform teeth on each side of the epistome, one formed by the anterior extremity of the lateral border of the buccal frame, the other by the external orbitary angle. Tarsi very much elongated. Length one inch.

Locality.—The Cape of Good Hope.



Hymenosoma orbiculare.

a, internal antenna; *b*, external antenna; *c*, right external jaw foot; *d*, abdomen of the male; *e*, abdomen of the female.

Mycteris. (Latreille.)

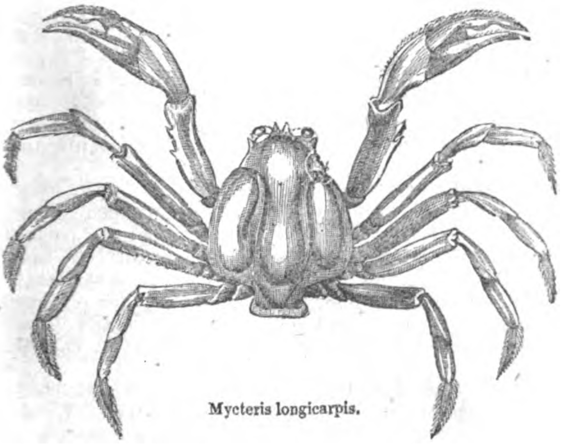
Generic Character.—Carapace extremely delicate, nearly circular, and very convex above. *Front* disposed nearly as in the *Ocypodes* [Ocypodians]; but the eyes, which are short and stout, have no orbitary cavity for concealment, and always remain projecting. The *internal antennæ* are very small, and placed as in the *Ocypodes;* the *external antennæ* are the longest. The disposition of the *mouth* is very remarkable. The external jaw-feet, instead of applying themselves horizontally to the buccal frame, remain nearly vertical, and form by their union a short and wide reversed cone, whose summit, directed downwards, is open and furnished with hairs; their lamellar portion (formed by the second and third joint) is very wide, and carries the succeeding joint at its anterior extremity; in front of the apophysis, situated at the base of these jaw-feet, and directed below for the support of the flagrum, the carapace presents a great notch, so that the afferent aperture of the respiratory apparatus is always gaping. The first pair of feet are very long, and are folded longitudinally upon the mouth; the succeeding feet are long, slender, and flattened. The abdomen has the same form in both sexes, and is enlarged towards the end. (M. Edwards.)

M. Milne Edwards is of opinion that these singular crustaceans establish, in some respects, the passage between the *Ocypodes*, *Pinnotheres*, and even certain *Macrura*, such as *Callianassa.* [Callianassa.]

Example, *Mycteris longicarpis.*

Description.—Carapace smooth and divided by furrows into three longitudinal portions; a small spine at the spot where the external orbitary angle is ordinarily found; anterior border of the carapace very much projecting, and furnished with hairs. Arms curved, and armed below with spiniform teeth; carpus very large; fingers long and curved. Length about one inch.

Locality.—Australasia.



Mycteris longicarpis.

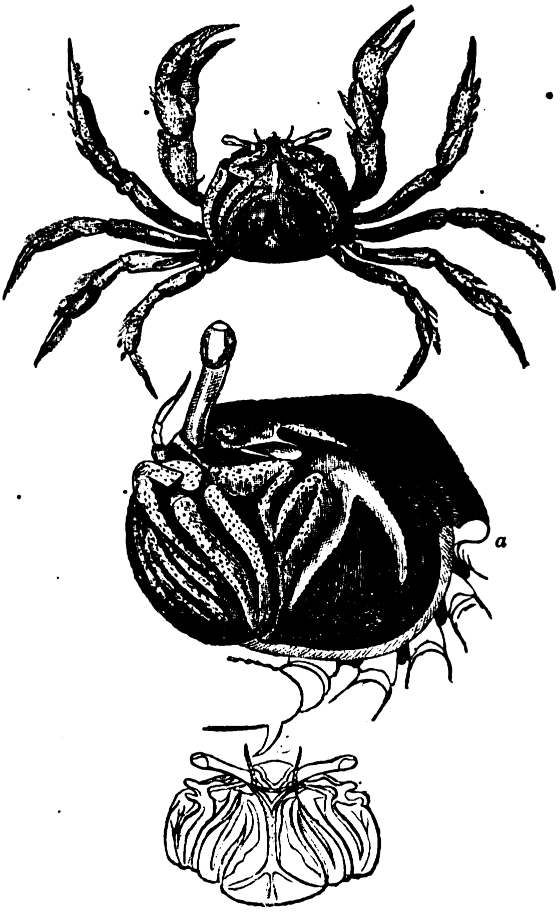
Doto. (M. Edwards.)

M. Milne Edwards remarks that he here places, not without doubt, a small and very remarkable crustacean which Savigny has figured in the great work on Egypt, and which M. Audouin has referred to the genus *Mycteris.* It approximates to the *Ocypodes* much in the general form of the body, in that of the feet, and in the disposition of the front, the antennæ, and the eyes; but it is distinguished from all the preceding *Catametopes* by the conformation of the *external jaw-feet* and the form of the *buccal frame.* This last is very wide behind, and narrow before; the third joint of the *external jaw-feet* is much larger than the second, and nearly entirely hides the succeeding feet, the first of which is inserted at its anterior and external angle. The palp, placed at the external side of these organs, bears a tolerable resemblance to that of the *Ocypodes*, for it does not carry at its extremity a multi-articulate filament, as is the case with the greater part of the *Brachyura.* M. Milne Edwards is of opinion that this crustacean establishes, by means of the organization of the buccal apparatus, the passage between the *Ocypodes* and the *Pinnotherians.*

Example, *Doto sulcatus* (*Cancer sulcatus*, Forsk.; *Mycteris sulcatus*, Audouin).

Description.— Carapace nearly square, and furrowed above; the front orbital border occupying nearly the whole of its width. Pterygostomian regions and external jaw-feet equally furrowed. Feet rather long and slightly compressed. Length about six lines.

Locality.—The Red Sea.



Doto sulcatus (enlarged).

a, profile view still more enlarged, without the legs, to show the grooves; *b*, detail of under part of carapace.

PINT, the half of a quart, and the eighth part of a Gallon, which is the standard measure connected with the pint.

PINTO, FERNAM MENDEZ, a celebrated Portuguese traveller, was born at Montemor-o-Velho, near Coimbra, of obscure parents, about 1510. He entered the service of a Portuguese gentleman, in which he continued eighteen months. An adventure, by which he had well nigh lost his life, but which he does not disclose, obliged him to emigrate, and he sailed in a vessel bound for the East Indies. Scarcely however had he lost sight of the coast of Portugal when the vessel was attacked and plundered by pirates, and Pinto was obliged to return to Lisbon, where he entered the service of Dom Francisco de Faria. Some time after, with the expectation of making his fortune, he embarked for India, and arrived at Diu in 1537, where he enlisted among the crew of a vessel designed to cruise against the Turks. He was captured at the entrance of the Red Sea, carried to Mocha, and there sold to a Greek renegado, and afterwards to a Jew, in whose possession he remained till he was redeemed by the Portuguese governor of Ormuz, who procured him the means of going to India. On his return to that country, Pinto met at Goa the captain-general of Malacca, Pedro de Faria, who took him into his service, and gave him the command of a small vessel employed in the trade with China. Having been attacked at the mouth of the river of Lugor by a Chinese pirate, who boarded and plundered his vessel, Pinto, though wounded, succeeded in making his escape, and arrived at Pattan, on the gulf of Siam.

Antonio de Faria (a brother of Pedro), on hearing the news of the loss of the vessel, swore he would have his revenge, and having enlisted a crew of Portuguese adventurers, and Pinto among them, he sailed from Pattan on the 19th of May, 1540. The Chinese pirate was overtaken, his vessel captured, and himself put to death. From this period Pinto's life seems to have been one of constant vicissitudes. He was one day the master of countless treasures, on the next groaning in captivity. In the intervals he was employed on a mission to Japan, and in other important transactions, which he fully describes in his work. He seems even to have entered at one time the Jesuit convent at Malacca, a circumstance which explains why the earliest account of his travels is found in the first collection of their letters, published in Italian, at Venice, in 1565, in letters written by him, and dated from the convent. He was present at the death of San Francisco Xavier; and Lucena, in his Life of that saint (*Historia da Vida do Padre Francisco Xavier*, Lisb., 1600), admits that he derived most of his information from papers procured from Pinto's widow. After twenty-one years' residence in various parts of the East Indies, China, Japan, Siam, &c., Pinto returned to his native country in 1558 (28th of September). He died at Almada, near Lisbon, but the year of his death is not known. The history of his travels and adventures was written for the amusement of his children. It abounds in gross exaggeration, and although there can be no doubt that Pinto visited the countries which he describes, it is also an ascertained fact that most of his descriptions are altogether imaginary, and that whatever curious and important matter is contained in his work is adulterated with idle and extravagant fictions. His expedition to the island of Calempluy, where, he tells us, 'he saw the tombs of the emperors of China,' and his route by land through part of the Chinese empire, are of this kind. Pinto's travels were not published until many years after his death, by Francisco de Andrade, Lisbon, 1614, in 4to., under the title of 'Peregrinaçam de Fernam Mendez Pinto,' &c. Six years after they were translated into Spanish by Francisco de Herrera, who added a prefatory discourse, intended to establish the authenticity of the narrative, Mad., 1620, fol. They were translated into French by Bernard Figuier (Paris, 1628 and 1645, in 4to., and 1830, 3 vols. 8vo.), and into English by H. Cogan (Lond., 1663, and 1692, in fol.). There are also editions of the original Portuguese work (Lisb., 1678, 1711, 1725, and 1762), with the 'Itinerario de Antonio Tenreiro.'

(Nicolas Antonio, *Bib. Nov.*, vol. ii., p. 380; Cardoso, *Agiologio Lusitano*, Lisb., 1652.)

PINTURI'CCHIO, BERNARDI'NO, born in 1454 at Perugia, was a disciple of Pietro Perugino, under whom he made great progress, and was often employed by his master as his assistant. He painted chiefly history, and also grotesque subjects, but he likewise excelled in portraits. Among his best portraits, peculiar praise is given to those of popes Pius II. and Innocent VIII., of Giulia Farnese, Cesare Borgia, and Queen Isabella of Spain. He executed numerous works at Rome and other cities of Italy: his manner was singular; he not only finished his paintings very highly, but endeavoured to give them unusual splendor, by introducing rich gilding blended with architectural ornaments, painted so as to resemble high relief, a style wholly incompatible with true taste and the simplicity and dignity of history. His most celebrated performance is the history of Pius II., painted in ten compartments, in the library of Siena, in which Raphael, then a very young man, and his fellow-student under Pietro Perugino, gave him some assistance.

The last work that he executed was a Nativity for the monastery of St. Francis at Siena, respecting which a story is told by Vasari and De Piles which seems eminently absurd and improbable. The monks, say they, assigned him a chamber where he might work undisturbed, from which, at his request, they removed the furniture, except a large old chest quite decayed by time. This too he insisted should be removed, in doing which it fell to pieces, and was found to contain 500 pieces of gold. This was a source of great joy to the monks, but the artist, say these writers, was so grieved that he had lost the treasure by his obstinately insisting on the removal of the chest, that he died of vexation a few months afterwards. How they ascertained that if he had suffered it to remain, he would have examined it and have stolen the treasure, they do not inform us. We suppose the artist himself did not say so. He died in 1413, aged 59. (Vasari; De Piles; Pilkington; Fuseli.)

PINUS, a genus of Gymnospermous Exogens, consisting for the most part of timber trees, inhabiting various temperate countries in the northern hemisphere. They are commonly called pine-trees, and are distinguished from the firs by their leaves, always evergreen, and needle-shaped, growing in pairs, threes, fours, or fives, surrounded by a membranous sheath at their base. In reality each parcel of leaves indicates a small branch axillary to a membranous, deciduous, withering leaf. The species are generally of great beauty as objects of ornament, or of much value on account of their timber, and are in much request by the planter: on which account we give a very brief enumeration of those species of which anything certain is known, the whole of which are actually in cultivation in Great Britain at this time.

Div. 1. *Scales of Cones truncate at apex.*

a. Leaves in pairs.

* *Scales of Cones spineless at apex.*

1. *The Scotch Pine* (Pinus sylvestris). Trunk erect. Leaves 2, short, glaucous. Cones ovate, stalked, and recurved, with rugged, truncated, depressed scales. This is the most hardy and valuable of all the pines. Its timber furnishes the red deal of the carpenters, and in Scotland, the climate of which country is particularly suited to it, the trees often acquire a great size, and highly picturesque appearance. It is however asserted that the quality of its timber is much deteriorated by being grown in warm districts. In England it is chiefly valued as a nurse to other trees, for which its hardiness and rapid growth render it well adapted. It forms an excellent screen in exposed sandy situations, where no other tree will thrive. Many varieties are known, of which an account will be found in Loudon's 'Arboretum Britannicum; of these the Pine of Haguenau, a village on the Rhine, is said to be the most important.

2. *The Dwarf Pine* (Pinus Pumilio). Trunk prostrate, dwarfish. Leaves 2, short, stiff, glaucous. Cones ovate, spreading, sessile, with depressed truncated scales. A small mountain species from the midland parts of Europe. Its timber is of no importance; in fact, from its small size, it can scarcely be said to yield any. It is probably an alpine form of *P. sylvestris*.

3. *The Hooked Pine* (P. uncinata). Trunk erect. Leaves 2, short, dark green. Cones oval, recurved, sessile, with pyramidal, recurved, truncated, or mucronated scales. A fine alpine tree, from the Pyrenees, and other European mountains, on the upper zone of vegetation, above P. sylvestris. It is extremely valuable for its hardiness and the great durability of its timber. The *P. Mughus* is apparently the same plant.

4. *The Red Pine* (Pinus resinosa). Trunk erect, lofty. Leaves 2, long, of a light somewhat glaucous green colour. Cones ovate-oblong, very obtuse, shorter than the leaves, pendulous, with rugged, rounded, truncated scales. A red-barked tree of large size from the northern parts of North America. The wood is fine-grained and of a close texture, and is highly esteemed in Canada for strength and durability. In appearance the species bear some resemblance to P Laricio.

5. *The Aleppo Pine* (Pinus halepensis). Trunk slender, erect. Leaves 2, long, slender, light green. Cones ovate, stalked, solitary, very regular in form, with depressed

truncated scales. A beautiful species, found wild in the western parts of Europe, from Genoa to Constantinople, and also throughout Syria. It grows fast, and is at once known by its fine light-green foliage; but its wood is not of much value, and it bears the climate of England with impatience.

6. *The Calabrian Pine* (Pinus Bruttia). Trunk erect. Leaves 2, slender, lax, pale green, very long. Cones sessile, in dense clusters, ovate, acute, very regular and even, with depressed truncated scales. A very handsome tree, inhabiting Calabria, and said to yield timber of excellent quality. It is very like the Aleppo Pine, but its cones are sessile and clustered, and it is much more hardy.

7. *The Banks Pine* (Pinus Banksiana). Trunk low, scrubby and straggling. Leaves 2, divaricating, oblique. Cones ovate, acuminate, horn-like, curved, erect, in pairs, grey, with rounded depressed truncated scales. An ugly tree, from the most southern parts of North America, where it is called the *scrub pine* and the *grey pine*. Its timber seems to be of little value, except for the construction of canoes, for which its lightness and toughness render it well adapted.

8. *The Pyrenean Pine* (Pinus Pyrenaica). Trunk erect. Leaves 2, long, fine, bright green, clustered at the end of the branches. Cones ovate, drooping, shorter than the leaves, with roundish truncated scales. A Spanish plant, inhabiting the Sierra de Segura, above the limits of the Aleppo Pine, on the Pyrenees, and elsewhere. Its timber is said to be of excellent quality and to have been used largely in the Spanish marine. It is reported to be a majestic species, and to be called by the Pyrenean peasants Pin Nazaron. It is the Pinus Hispanica of some collections.

9. *The Pallas Pine* (Pinus Pallasiana). Trunk erect, with horizontal branches when old. Leaves 2, dark green, very long, and stiff. Cones curved, horizontal, ovate oblong, as long as the leaves, with roundish truncated scales. A fine tree from the central parts of the Crimea, with the habits of the Pinaster. Wood resinous and durable, but difficult to form into good planks on account of being unusually knotty. The resin is stated to be very pleasant to the smell.

10. *The Stone Pine* (Pinus Pinea). Trunk erect; when old, flat-headed. Leaves 2, long, stiff, dark-green; when the plant is very young, small and glaucous. Cones roundish, polished, with rounded truncate scales. Seeds large, oblong, with a very short wing. An inhabitant of the southern parts of Europe and the Levant, where the wood is often used in ship-building, and the seeds, which are large and like nuts, are eaten. On the latter account it has accompanied Europeans in their migrations, and has now become common in many parts even of the southern hemisphere. The seeds are called pignons by the French. In Naples there is a variety with the shell of the seed thin and tender. The timber of this species is said to be whiter and rather more durable than that of the Pinaster.

11. *The Black Pine* (Pinus Austriaca). Trunk erect, with horizontal branches when old. Leaves 2, dark-green, glossy, straight, stiff, from three to five inches long. Cones conical, horizontal, shorter than the leaves, polished, and pale-brown. It is found among the rocks and precipices of southern Germany, and derives its name from the peculiarly dark colour of the foliage. The most sterile soil is said to suit it. The timber is reported to be valuable, but coarse; and to resist alternate dryness and moisture better than the larch.

12. *The Corsican Pine* (Pinus Laricio). Trunk very erect and tall. Leaves in pairs, long, deep green, distant, rather loose. Cones ovate, horizontal, shorter than the leaves, with roundish rugged truncated scales. A noble tree from the mountains of Corsica, Greece, Turkey, and Spain. It grows faster than any other known species, and produces excellent timber, similar in quality to red deal, but more brittle and less elastic. The French use it extensively in ship-building. The tree is now becoming common in this country.

** *Scales of Cones spiny at apex.*

13. *The Cluster Pine* (Pinus Pinaster). Trunk lofty, erect. Leaves 2, long, stiff, dark green. Cones clustered, recurved, conical, shorter than the leaves, with pyramidal scales terminated by a small rigid spine. A noble species, inhabiting the most sterile sandy plains of France and Southern Europe, especially along the coast. Its timber is soft, light, coarse, and only fit for very common purposes; but it affords a large quantity of resin and tar, and is much consumed in the manufacture of lampblack. It is this species that has been so successfully employed in fixing the loose drifting sand of the barren plains of some parts of France. An excellent account of it is given by Mr. Loudon, in his 'Arboretum Britannicum,' p. 2219. Many varieties are known, of which the most remarkable are, that called *P. Lemoniana*, with an irregular stunted zigzag habit, first observed upon the property of Sir Charles Lemon in Cornwall, and the *P. escarena*, a very vigourous variety introduced from Nice by the present earl of Aberdeen. *Pinus Massoniana*, a Chinese plant, is said to be the same as this.

14. *The Prickly Pine* (Pinus pungens). A large tree. Leaves 2, short, compact, pale green. Cones ovate, clustered, drooping, longer than the leaves, with hard pyramidal scales terminated by a stiff strong spine. A native of Virginia and North Carolina. The timber seems of no value. The aspect of the tree is something like that of the Scotch Pine, but it is paler. Its cones hang on the branches for many years. Mr. Loudon states that at Dropmore there are cones of more than twenty years of age still adhering to the trunk and larger branches.

15. *The Yellow Pine* (Pinus mitis). A fine tree. Leaves 2, long, slender, dark green. Cones ovate, pendulous, shorter than the leaves, with depressed roundish scales, armed with a small spine. Young shoots violet. A common inhabitant of the pine-forests of North America, as far north as Connecticut and Massachusetts. Its timber is of great value for domestic and naval architecture, provided the sap-wood, which is very perishable, is first removed. It is regarded as a most durable timber in this country.' In America it ranks next in quality to the P. Australis or *Southern Pine*. P. variabilis is one of its garden names.

16. *The Jersey Pine* (Pinus inops). A low gnarled tree. Leaves 2, dark green, from two to three inches long. Cones recurved, ovate-oblong, straight, longer than the leaves, with spiny spreading scales. Young shoots violet. A native of the more southern states of the American union. Its timber is of little use except for fuel. In this country it is usually a miserable-looking species, evidently unsuited to the climate. Like the Banks Pine, it is called Scrub Pine in the United States.

b. Leaves in threes.

* *Scales of Cones spineless at apex.*

17. *The Chinese Pine* (Pinus sinensis). A large tree. Leaves 3, slender, deep green, serrulated. Cones ovate, brownish, on short stalks, with flattened truncate unarmed scales. Native of China. Very little is known of it, except from Chinese drawings. It only exists in the garden of Mr. Wells, of Redleaf, near Tunbridge, where it is found to be 'tolerably hardy.' This seems to be the pine found on the Khoseea Hills of India, and regarded as a variety of Pinaster by Professor Royle.

18. *The Noble Pine* (Pinus insignis). Leaves 3, grass-green, a little wavy, irregularly arranged, longer than the cones. Cones ovate, bright brown, obtuse, with rounded depressed obtuse scales, the lowermost of which are longer than the others, and more or less hooked back. A beautiful species, native of California, remarkable for its bright dense grass-green foliage. Nothing is known of its native habit. It is rather too tender for the latitude of London.

19. *The Canary Pine* (Pinus canariensis). Trunk stout, erect. Leaves 3, very long, rough-edged, wavy, grass-green. Cones oblong, woody, five or six inches long, with prominent large pyramidal straight scales, terminated by a hard blunt callosity. A native of the mountains of Teneriffe and Canary, where it forms large forests, and often acquires an enormous size. The timber is said to be very resinous and durable. The species is too tender for England.

20. *The Ocote Pine* (Pinus Ocote or Teocote). Leaves 3, wavy, rough, light green. Cones obtuse at the base, ovate, smooth, with pyramidal angular blunt scales. A Mexican plant, of which little is known. It is found on M. Orizaba, and near Real del Monte, and forms a tree 100 feet high.

21. *The spreading-leaved Pine* (Pinus patula). Leaves 3, very slender, spreading. Cones ovate, oblong, polished, with small angular truncated prominent scales. Native of Mexico. A lofty tree, with leaves eight or nine inches long. It occurs in the northern provinces of Mexico.

* * *Scales of Cones spiny at the apex.*

22. *The southern Pine* (P. australis or P. palustris). Trunk erect, very cylindrical, and stiff. Leaves 3, very long,

grass-green, clustered at the ends of the branches. Cones ovate-oblong, seven or eight inches long, with depressed scales, armed in the middle with a small prickle. A native of Virginia and the neighbouring states of America to the south, where it acquires the height of from 60 to 70 feet, with a trunk from 15 to 18 inches in diameter for two-thirds of its length. Its timber is of excellent quality, light, clean, and durable, and is extensively employed in ship-building, particularly for masts. It also yields abundance of tar. It is unfortunate that this, the handsomest and the best of the North American pines, should be too tender for the climate of England.

23. *The Frankincense Pine* (Pinus Tæda). Trunk lofty, straight. Leaves 3, pale green, stout, straight. Cones curved, oblong, the length of the leaves, with compressed woody prominent scales, armed with a sharp point. A tree said to acquire the height of 80 feet, in the *barrens* of Florida and Virginia, but not much known in England, where it seldom thrives. There are however some fine specimens at Pain's Hill, and at other places near London. The timber is soft and perishable, but it yields a fragrant turpentine plentifully.

24. *The Pitch Pine* (Pinus rigida). Trunk lofty, straight, much branched. Leaves 3, of variable lengths. Cones clustered, sessile, ovate, with rugged compressed pyramidal scales, terminated by a small hooked spine. Found in poor soil in most parts of the United States, and even inhabiting salt-marshes overflowed by the sea. It has a thickish dark-coloured bark, and, in consequence of the number of its branches, has an unusually knotted structure. The wood yields tar in abundance, but is coarse-grained and of inferior quality. When growing in swamps, it has little or no heart-wood.

25. *The Pond Pine* (Pinus serotina). Trunk much branched. Leaves 3, very long (five or six inches). Cones roundish-ovate, in pairs, with prominent rounded scales, armed with a firm short brittle prickle. An obscure species, probably not distinct from the Pitch Pine. It forms a small tree, whose wood is of bad quality, and is found from New Jersey to Carolina in wet places, by the side of ponds, &c.

26. *The heavy-wooded Pine* (Pinus ponderosa). Trunk very rugged, and irregularly branched. Leaves 3, very long and strong. Cones small, oblong, with strong pyramidal scales terminated by a small recurved prickle. A large tree, with the habit of the Corsican pine. It was found in North-West America, by Douglas, and is a very rapid grower. The growth of the tree is however inelegant, and its timber, though heavy and durable, very coarse. In its native country it is infested with the Viscum Oxycedri, a parasitical plant.

27. *The Sabine Pine* (Pinus Sabiniana). Trunk straight, erect; the young shoots covered by a glaucous bloom. Leaves 3, very long and lax, glaucous, and serrated. Cones very large, roundish ovate, with large pyramidal hooked scales. A noble Californian tree, with a trunk from 110 to 140 feet high, and from 3 to 12 feet in diameter, clothed with branches to the ground, when standing far apart or solitary. The wood is white, soft, and not durable. The cones are often six inches in diameter, and are very hard, heavy, and woody.

28. *The Coulter Pine* (Pinus Coulteri). Trunk straight, erect; the young shoots covered with a glaucous bloom. Leaves 3, very long and stiff, glaucous, and serrated. Cones very large, oblong, with long wedge-shaped, rigid, woody, horned scales. A fine tree, from California, very like the Sabine Pine, and the two are perhaps too nearly related. The cones are however still larger and heavier than in that species, and more oblong, and the seeds are smaller. It is called P. macrocarpa in gardens.

29. *The long-leaved Pine* (Pinus longifolia). Trunk erect, with a coarse rugged bark, and whorled branches. Leaves very long, drooping, slender, bright green, channelled, and serrated. Cones shorter than the leaves, oblong-ovate, woody, and rugged, with pyramidal, obtuse, mucronate, corky, recurved scales. Seeds large, eatable. An Indian species, inhabiting the valley and lower hills of Nepaul. It is extremely beautiful, but too tender for the climate of England.

30. *The Neoza Pine* (Pinus Gerardiana). Trunk lofty, with a conical head. Leaves 3, short, stiff, glaucous, obsoletely serrated, with deciduous sheaths. Cones very like those of P. longifolia. Seeds large, eatable. A native of the coldest forests of the Himalayas, and chiefly occupying the dry bleak face of the Tartarian side of those mountains. It is represented to be a large tree, conical in form and compact in habit. The cones from 9 to 10 inches long. The Chilghoza Pine is thought to be the same thing.

c. Leaves in fives.

* *Scales of Cones spineless at apex.*

31. *The Egg-fruited Pine* (Pinus oocarpa). Leaves 5, slender, from 8 to 11 inches long. Cones roundish, ovate, polished, hard, with truncated scales. From the pine-region of Mexico, and also from the warmer valleys, forming a tree from 30 to 40 feet high.

32. *The Smooth-leaved Pine* (Pinus leiophylla). Leaves 5, very slender, 3 or 4 inches long, rough-edged, light green. Cones ovate, 2 inches long, on a short stalk, with truncate depressed scales, a little hollowed. An inhabitant of the cold regions of Mexico. Nothing is on record of its habit.

33. *The Montezuma Pine* (Pinus Montezumæ). Leaves 5, rather rigid, rough-edged, about 6 inches long. Cones ovate, oblong, bright brown, about as long as the leaves, with elevated, rugged, truncated scales. A native of the mountains of Mexico to the height of 11,000 feet above the sea.

34. *The Thread-leaved Pine* (Pinus filifolia). Leaves 5, from 12 to 15 inches long, acutely triangular. Cones sessile, ovate-acuminate, woody, hard, curved, 9 inches long, 3 inches in diameter at the base, with lozenge-shaped pyramidal depressed scales, and a hard woody compressed callous mucro in the middle. A noble pine, found in Guatemala by Mr. Hartweg. Nothing is yet known of its habits or timber.

35. *The Acapulco Pine* (Pinus Acapulcensis). Leaves 5, thin, short, very glaucous, as well as the shoots. Cones pendulous, ovate, acute, whorled, with pyramidal erect tapering scales, often contracted in the middle. Leaves about 6 inches long. Cones closely covered with pyramidal elevations, about 4 inches long. Found in Mexico, in ravines near Acapulco, growing 50 feet high.

36. *The False Weymouth Pine* (Pinus Pseudostrobus) Leaves 5, very fine, and glaucous. Cones ovate, whorled, horizontal, about 4 inches long, by an inch and a half in breadth over the middle, with pyramidal erect scales. A Mexican pine, with the habit but not the cones of a Weymouth pine, found very commonly at Anganguco, about 8000 feet above the sea.

37. *The Bedford Pine* (Pinus Russelliana). Leaves 5, very long. Cones tapering, horizontal, a little drooping, nearly straight, from 7 to 8 inches long, about 2 inches wide near the base, and almost acute at the upper end, with pyramidal straight obtuse scales. Native of Mexico near Real del Monte.

38. *The Devonshire Pine* (Pinus Devoniana). Leaves 5, very long. Cones pendulous, solitary, horn-shaped, from 9 to 10 inches long, about 3 inches in diameter near the base, and tapering to 1¾ inches, with rounded, obtuse, polished scales. A species called in Mexico *Pino blanco* or *P. real*, forming a large tree 60 or 80 feet high, between Real del Monte and Regla. The young branches are nearly an inch in diameter.

39. *The Hartweg Pine* (Pinus Hartwegii). Leaves 4, very slender, about 6 inches long. Cones pendulous, oblong, obtuse, clustered, about 4 inches long, with depressed truncated scales, having a projecting callosity in the middle. A Mexican tree 40 or 50 feet high. The cones are of a clear greyish-brown, and of nearly the same diameter throughout.

** *Scales of Cones spiny at apex.*

40. *The West Indian Pine* (Pinus occidentalis). Leaves 5, pale green, slender, much longer than the cones. Cones ovate-oblong, obtuse, stalked, with rounded, angular, prominent scales, tipped by a sharp prickle. A native of St. Domingo, on the mountains where snow occasionally falls.

41. *The long-leaved Pine* (Pinus macrophylla). Leaves 5, from 14 to 15 inches long. Cones straight, horizontal, ovate, tapering, solitary; 6 or 7 inches long, and about 3 inches broad at the base, with the ends of the scales strongly hooked backwards. A small tree from the North of Mexico.

Div. 2. *Scales of Cones flat, and compressed at the apex.*

42. *The Mexican Cembra* (Pinus Cembroides or Llaveana). Leaves 3, short, tufted, glaucous, and twisted.

Cones small, roundish-ovate, hard, with elevated roundish obtuse scales. Seeds large, eatable. A small Mexican tree, occurring in large forests, and producing seeds similar to those of the Stone and Neoza pines.

43. *The Cembra Pine* (Pinus Cembra). Tree erect, conical. Leaves 5, with no sheath, short, stiff, glaucous green. Cones ascending, oblong, about the length of the leaves, with thin callous-pointed scales. Seeds large, without wings. A tree of considerable size, inhabiting the sides of mountains in Siberia, Tartary, Switzerland, and Italy. It is very ornamental and hardy, grows tolerably fast, and produces a fragrant, fine-grained, soft wood, well suited for carvers and turners. The seeds yield a large quantity of oil of good quality.

44. *The Weymouth Pine* (Pinus Strobus). Trunk erect, very lofty. Leaves 5, slender, bright green, without sheaths. Cones narrow, long, pendulous, from 5 to 6 inches long, with thin ovate callous-pointed scales. A native of Canada, and others of the more northern districts in North America. It grows very fast, and produces the clean, soft, white, but perishable timber imported from America under the name of 'Pine.' Of this species, *P. monticola* of Douglas, seems a mere variety.

45. *The Lofty Pine* (Pinus excelsa). Trunk erect, very lofty. Leaves 5, bright green, distinctly glaucous on one side, with no sheath, leaves narrow, long, pendulous, stalked, from 6 to 7 inches long, with thin lax, ovate, callous-pointed scales. A fine Himalayan tree, bearing the climate of England without protection. It has very much the habit of the Weymouth pine, but its leaves are more glaucous and the cones are larger.

46. *The Lambert Pine* (Pinus Lambertiana). Trunk erect, very lofty. Leaves 5, rather stiff, bright green, roughish, with no sheaths. Cones very large, pendulous, from 14 to 18 inches long, with broad rounded scales. Seeds large, eatable. An enormous tree found by Douglas in New Albion, on sandy plains where no other vegetation exists. Specimens were found 200 feet high and more. The wood is spongy, and of no value except for fire-wood. The seeds are collected by the Indians for food.

47. *The Ayacahuite Pine* (Pinus Ayacahuite). Leaves 5, with deciduous sheaths, slender, very glaucous on one side, sharp-pointed, from 2 to 4 inches long. Cones drooping, a foot or more long, very slender, with distant, oblong-lanceolate, obtuse, spreading scales. A gigantic tree resembling the Weymouth pine in habit; found by Ehrenberg near Omitlan in Mexico, and by Hartweg in Guatemala. It produces an unusually large quantity of a clear, bright, amber-coloured resin.

Besides the foregoing, the following species of Pine are mentioned in books, but they are too imperfectly known to be worth further notice in this place: viz. *P. californiana* or *montereyensis, timoriensis, muricata, tuberculata, radiata, contorta, squamosa, turbinata.*

(Loudon's *Arboretum et Fruticetum Britannicum*, vol. iv.; Lambert's *Monograph of the genus Pinus.*)

PINUS BALSA'MEA. [ABIES, p. 30.]

PINYARI. [HINDUSTAN D. 219.]

PIOMBI'NO. [SIENA.]

PIOMBO, SEBASTIAN DEL, an eminent painter, both of portrait and history, was born in 1485, at Venice, whence he was called also Veneziano. His surname, according to Lanzi, was Luciano, though it does not appear that he was known by it in his own time, or that he ever marked his pictures with it. On his principal performance in oil, the Raising of Lazarus, the words 'Sebastianus Venezianus faciebat' appear in characters no doubt traced by himself. He was a skilful musician, particularly on the lute, but abandoned that science for painting, the rudiments of which he acquired under Bellini, but afterwards became the disciple of Giorgione, whose style of colouring he carefully studied and successfully imitated. He first distinguished himself as a portrait painter, to which his powers were peculiarly adapted. His portraits are boldly designed and full of character; the heads and hands are admirably drawn, with an exquisite tone of colour and extraordinary relief. The most famous of his works in this class were portraits of Giulia Gonzaga, the favourite of Cardinal Hippolito de' Medici, which by writers of that age was called a divine performance, and of Pietro Aretino, in which he distinguished five different tints of black in the dress, imitating with wonderful exactness the difference of the velvet, the satin, and other materials of the drapery.

The first historical picture which established his reputation was the altar-piece in the church of S. Gio. Crisostomo, at Venice, which from its richness and harmony of colouring has frequently been mistaken for a work by Giorgione. Sebastian was invited to Rome by Agostino Chigi, a rich merchant, who traded at Venice, by whom he was employed in ornamenting his palace of the Farnesina, in conjunction with Baldassare Peruzzi, where Raffaelle had painted his celebrated Galatea. Thus painting in competition, he found his own deficiency of invention, to remedy which he studied the antique, and obtained the instruction and assistance of Michael Angelo. Indeed it is said that that illustrious painter, growing jealous of the fame of Raffaelle, availed himself of the powers of Sebastiano as a colourist, in the hope that, assisted by his composition, Piombo might successfully rival the efforts of Urbino. Michael Angelo accordingly furnished the designs for the Pietá, in the church of the Conventuali at Viterbo; and the Transfiguration and the Flagellation in S. Pietro, in Montorio, at Rome, the execution of which however, in consequence of Piombo's tedious mode of proceeding, occupied six years. The extraordinary beauty of the colouring and the grandeur of Michael Angelo's composition and design, in these celebrated productions, were the objects of universal surprise and applause.

At this time cardinal Giulio de' Medici commissioned Raffaelle to paint his picture of the Transfiguration, and being desirous of presenting an altar-piece to the cathedral of Narbonne, of which he was archbishop, he engaged Sebastiano to paint a picture of the Raising of Lazarus, of the same dimensions. 'On this occasion,' says Bryan, 'he was again assisted by the powers of Buonarotti, by whom it was composed and designed. The picture was publicly exhibited at Rome, in competition with the Transfiguration; and it is no mean proof of its extraordinary merit, that, notwithstanding the transcendent beauty of Raffaelle's chef-d'œuvre, Sebastiano's performance excited universal admiration.' This picture was removed, by the regent of France, from the cathedral of Narbonne into the Orleans collection, whence it was purchased by the late J. J. Angerstein, Esq., for two thousand guineas, and is now deposited in the National Gallery. It is painted on canvas, and its size is thirteen feet six inches high, by nine feet five inches wide.

Sebastiano was greatly patronised by Pope Clement VII., who conferred upon him the office of keeper of the papal signet, which was the cause of his name, Del Piombo, in allusion to the lead of the seal. This post rendering it necessary that he should assume a religious habit, he abandoned the profession of a painter, and was thenceforth called Frate Bastiano del Piombo. His last work was the chapel of the Chigi family, in Santa Maria del Popolo, which he left imperfect, and it was afterwards finished by Francisco Salviati. He died of a fever, at Rome, in 1547, at the age of sixty-two years. He is said to have been the inventor of painting upon walls with oil-colour, and of preventing the colours from becoming dark by applying, in the first instance, a mixture of mastic and Grecian pitch, or, according to some authorities, a plaster composed of quick-lime, pitch, and mastic.

'Portrait, in its most genuine sense,' observes Fuseli, 'was the province of Sebastiano. Nature had given him an eye to penetrate and, with practice, to transcribe the character and beauties of single objects, but had refused him all ideal power—that energy of mind which commands and unites a numerous whole. As slow and irresolute in conceiving, as ambitious of painting historic subjects, he readily promised what he began with reluctance and finished with fatigue.'

(Lanzi, *Storia Pittorica*, iii. 66; Pilkington's *Dict.*, by Fuseli; Bryan's *Dict.*)

PIOZZI, MRS., was originally Miss Esther Lynch Salusbury, being the daughter of John Salusbury, Esq., of Bodvel in Carnarvonshire, where she was born in 1739. Her good looks and vivacity early acquired her some distinction in the London world of fashion, which ended in her marriage, in 1763, to Mr. Henry Thrale, an opulent brewer in Southwark, and then one of the members for that borough. It was soon after she became Mrs. Thrale that her acquaintance with Dr. Johnson commenced, which is the circumstance to which her name principally owes any place it may hold in the annals of our literature. But Thrale having died in 1781, his widow retired, with her four daughters, to Bath, and there, having met with an Italian music-master, of the name of Gabriel Piozzi, fell in love with and married him in 1784; and that proceeding, from which her old friend earnestly endeavoured to dissuade her, produced a complete rupture between them a short time before Johnson's death. This nevertheless did not prevent Mrs. Piozzi from publishing, in 1786, an octavo volume of gossip, entitled 'Anecdotes of Dr. Samuel Johnson, during the last Twenty Years of his Life.' Many things in this publication gave great offence to Boswell and Johnson's other friends, who professed to regard it as having been prompted mainly by feminine spite and revenge; but although they might not be far wrong in this conclusion, there was also ground for some retaliation from the other side; and the view which a large portion of the public took of the feud between the parties may be seen in Dr. Wolcot's (Peter Pindar's) humorous poem entitled 'Bozzy and Piozzi.' Meanwhile Mrs. Piozzi followed up her first book by another, in 1788, entitled 'Letters to and from Dr. Samuel Johnson,' in two vols. 8vo. But before this she had gone with her husband to Florence, and there, in conjunction with three gentlemen, named Merry, Greathead, and Parsons (the once famous but now almost forgotten founders of the Della Crusca school of poetry), she printed but did not publish, in 1786, a collection of pieces in prose and verse, under the title of 'The Florentine Miscellany.' Mrs. Piozzi's other works are, 'Observations and Reflections made in the course of a Journey through France, Italy, and Germany,' two vols. 8vo., 1789; 'British Synonymy, or an Attempt at regulating the Choice of Words in Familiar Conversation,' 2 vols. 8vo., 1794; and 'Retrospection, or a Review of the most striking and important Events, Characters, Situations, and their Consequences, which the last Eighteen Hundred Years have presented to the view of Mankind,' 2 vols. 4to., 1801. She is said to have also contributed many anonymous pieces, both in prose and verse, to the periodical publications of her day; but it has generally been admitted that nothing she wrote at a later date is so good as some poems she contributed so early as in 1765 to the volume of 'Miscellanies' published by Anna Maria Williams, particularly one called 'The Three Warnings,' the superior merit of which, rather than any proper authority for the fact, has led to the opinion that she was materially assisted in its composition by her friend Johnson. It certainly however is not much in Johnson's style. Mrs. Piozzi survived her second husband, and died at Clifton near Bristol, on the 2nd of May, 1821.

PIPA. [Frogs, vol. x., p. 493, 496.]

PIPE. A column of air contained in a tube and maintained in a state of vibration yields a musical sound, depending upon its length and (slightly) upon the state of the atmosphere. Our object in the present article is to give such an account of the theory of a musical pipe as may, with the articles Acoustics, Cord, Harmonics, Scale, Temperament, &c., complete the statement of the leading principles of sound and doctrines of music.

We shall begin by correcting one mistake in each of the articles Acoustics and Cord. In the former (p. 97) the number of vibrations of the middle A of the treble clef is given; these, with the meaning of the term vibration as used in that article, should all be doubled, since the numbers there given (from the Berlin Transactions) mean complete or double vibrations, answering to double waves of sound (or a condensation and rarefaction in each). The mean value in that page gives 430 double vibrations for the note A, a result we shall presently use. Dr. Smith, in his Harmonics (1749), found, by comparison of an organ-pipe with a wire, that the D next below the A just mentioned gave 254, 262, and 268 double vibrations per second in a cold day of November, a temperate day of September, and a warm day of August: taking 262 as the mean, this would give only 393 double vibrations for A instead of 430. If then all the experiments are trustworthy, the A of Dr. Smith's organ (at Trinity College, Cambridge) must have been nearly a tone below that of the orchestras of our day.

We have often heard it said that what is called concert-pitch had risen considerably in the last century, but we had no idea, till we met with Dr. Smith's experiment, that there was any positive foundation for the assertion.

Throughout the formulæ in the article Cord g must be read[*] instead of $2g$. The result of the example [page 6, Cord] should be 323·8 instead of 458.

In this subject a distinct line should be drawn between those circumstances which are of easy and difficult explanation: for example, to a person who thoroughly understands the composition of waves moving in opposite directions [Acoustics, pages 93, 94] it is not difficult to point out what the state of a pipe must be when in musical vibration; but to explain how the action of a current of air, as in the common flute, or the joint action of the air and a reed, as in the clarinet or reed-stops of an organ, produces and maintains this state of vibration, is quite another thing.

We shall first consider the pipe in a state (no matter how produced) of continued sonorous vibration, yielding the lowest note which it will give: let it be a simple pipe open at both ends, and let it be sounding, say the C of the treble clef next below the A above mentioned, or the first below the lines of that clef. This note requires 258 double vibrations per second, A requiring 430. If we now remember that the air at the two extremities is in communication with the outer air, we see that no condensation or rarefaction can take place at those extremities, or only very small ones compared with those which take place in the interior of the tube. To get approximately at the conditions of vibration, let us suppose that no condensation or rarefaction takes place at the extremities. We then see [Acoustics, pp. 93, 94] that the state of the pipe, its two extremities never being condensed or rarefied, is as it would be if two waves of sound were travelling in opposite directions, every particle of the interior being affected by the joint condensations and velocities of both. Moreover, the distance between two uncondensed particles is always the whole length of the wave of condensation or that of rarefaction, or a multiple of this length; that is, the pipe must be either the half-length of a double wave or a multiple of this half-length. When the pipe sounds the lowest note, it must give the longest wave; that is, the length of the pipe must be that of the simple wave of condensation or rarefaction. Hence the lowest note which a pipe can yield, which is called its *fundamental* note, is that belonging to a double wave of sound which is double of its length. Each double wave answers to a complete or double vibration of a string.

To compare this result with practice, let us suppose sound to travel at the rate of 1125 feet per second (temperature 62° Fahr.). The note C having 258 double vibrations per second, this 1125 feet must contain 258 double waves, or each double wave must be 4·36 feet. The single wave then is 2·18 feet, or 2 feet 2 inches and ·36 of an inch, which is the *theoretical* length of the pipe. Now the organ-builders say 2 feet [Organ, Construction of, vol. xvi., p. 498], but this of course is a rough description, since the French organ-builders also say 2 feet (according to Biot), and the French foot is longer than the English. Further on in the article referred to we see 2 feet 2 inches given as the length of this C in an open pipe (the dulciana), and 1 foot 1 inch in a stopped pipe (the stopped diapason), which, as we shall presently see, ought to be half as long as an open pipe. The common flute, when everything is stopped, gives this same C, and the length from the embouchure (or mouth-hole) to the end of the instrument is a little more than 2 feet, but certainly never 2 feet 2 inches. It must be remembered however that this instrument is made up of the flute (so called) and the player, whose lips, when they come over the embouchure, confine the air, and are equivalent to a slight lengthening of the pipe. It is not the manner of blowing which does this, but the approach of the lips, as may be thus shown. Take a common flute, and, without holding it to the lips, strike the uppermost hole with the finger; a faint sound will be heard. Now approach the lips to the embouchure, but without blowing, and then strike the same hole with the finger; another faint sound will be heard, decidedly flatter than the former. It is well known to those who play on this instrument (to those who play in tune at least) that drawing the lips back, so as not so much to confine the air contiguous to the embouchure, sharpens the tone, and what some persons call *humouring* the instrument means continual alteration of the position of the lips, so as to shorten or lengthen the pipe by turns, according to the note to be sounded. It is also well known to players that this humouring can be carried to a much greater extent with the high notes than with the low notes; but so little were the practical musicians in connection with the theoretical in the time of Daniel Bernoulli (who first gave the mathematical theory of this subject), that this simple fact was only discovered by him from a new and somewhat complicated experiment.

---

[*] The cause of this error is an inadvertency in the article *Sound* in the 'Encyc. Metrop.,' the distinguished author of which has himself forgotten that he was using g in a different sense from the usual one, and (p. 780) makes the velocity of a pulse along a stretched cord to be that acquired in falling down the length of the portion of the cord whose weight is equal to the tension, whereas it should have been half that length.

In the preceding theory all the parts of any section of the pipe perpendicular to its axis are supposed to vibrate in the same manner. This cannot be the case in the common flute or in the organ-pipe, in which the cause of condensation is supplied at the side; and in fact all experiments in which the cause of undulation has been equally applied over all the parts of a section perpendicular to the axis, have agreed in the result that the time of vibration is wholly independent of the diameter of the tube: while those in which the same was not equally applied give the result that the greater the diameter the lower is the tone. Moreover, when an orifice is made in the side of a pipe, as in the flute, it is not equivalent to the formation of a new pipe terminating at that orifice, though the results are somewhat resembling. Any note between the fundamental note and its octave may be obtained by an orifice of one size or another made at or near the middle of a pipe.

We have seen that we may suppose the extremities of the open pipe to contain between them 2, 3, &c. half-waves, which, the whole pipe being one half-wave in length, will give the Harmonics of the fundamental note. This subject is sufficiently treated in the article cited.

Various instruments yield different harmonics more or less readily; the general rule being that the more violent the agitation which produces the sound, the larger the number of half-waves formed in the tube, and the higher the harmonic: also that a certain diameter, the larger the greater the length of the tube, is necessary to the production of the fundamental note. Thus, if an organ-pipe be too small in the bore, it will yield the octave of the fundamental note; or if the latter, only with great attention to the *voicing*, or adjustment of the orifice through which the wind enters. If the bore of a flute be too narrow (which we imagine to be the case in modern instruments), the lower notes will be difficult to obtain. And the various harmonics are produced with very different degrees of facility; a circumstance of which the theory can give no account. Thus, players on the trumpet find it exceedingly difficult to produce that tone which divides the instrument into seven parts, or the flat seventh in the third octave above the fundamental note; while in the flute there is no moderately skilful player who cannot produce it. It is to be observed however that all pipes of the trumpet class are of tapering diameter; and though they agree in all material points with the theory of cylindrical and prismatic pipes, it is not remarkable, in the present state of the mathematical analysis of this subject, that they should present circumstances difficult of explanation.

It will be obvious, from the considerations in Acoustics, that when the extremities of the pipe contain between them n half-waves, there will be $n+1$ points (the orifices included) at which the velocities are always greater than elsewhere, and no condensations or rarefactions; and n points (in the middle of the subdivisions), at which the condensations or rarefactions are always greater than elsewhere, and which are always at rest or nearly so. These immoveable points are called nodes of vibration; and there is one of them in the middle of the tube only when the number of half waves in the pipe is odd.

Let us consider the case of a pipe with one end closed. It is obvious now that the open extremity is a point of no condensation, while the closed extremity must be a node, or point of no velocity. Hence the tube must be the half of an odd number of simple waves in length, twice the tube must be an odd number of simple waves, and four times the tube an odd number of double waves in length. Hence the fundamental note belongs to a double wave of four times the length of the tube; so that the fundamental note of a pipe closed at one end is an octave lower than that of the same pipe open at both ends. It is the same thing to say that a pipe of half the length of an open pipe, closed at one end, gives the same note as the open pipe. This is the reason why the pipes of the stopped diapason stop of an organ are halves of the lengths of those of the open diapason.

Again, since the double length of the pipe is an odd number of simple waves, the harmonics which the pipe can yield are not the complete set yielded by the open pipe of double the length, but every other one, beginning from the fundamental note. The number of vibrations per second being 1, those of the harmonics producible by the pipe closed at one end, are 3, 5, 7, &c. We will leave the pipe closed at both ends (a matter of no practical concern, since its sound could not be heard) to the student; the result he should arrive at by the preceding considerations, is that it is in all respects analogous to the vibrating Cord fixed at both ends. But he must not infer, by a reversed analogy, that the vibrations of an elastic body fixed at one end (as the spring of a tuning-fork) answer to those of a pipe closed at one end, since their law is very different.

It is usual first to give the theory of a closed pipe, and then to suppose the open pipe made of two closed pipes, with their closed ends together, and their closing diaphragms removed. The opposition of the vibrating movements will then keep the particles in the middle at rest. This is a sufficient explanation of those modes of vibration of the open pipe in which there is a node in the middle.

We now come to the explanation of the manner in which the sonorous vibration of a pipe is maintained. If we suppose a vibrating body placed at the orifice, it is found that if the vibrations of the body be equal or nearly equal to those of the fundamental note of the tube in the preceding theory, or one of its harmonics, the sound of the vibrating body is reinforced by the tube. A slight alteration of the tube, though it may sharpen or flatten the note, does not by any means produce such a difference as would be caused by the same alteration, if the sound were caused by the tube alone. We do not intend to go into this subject; the reader may find it discussed, both mathematically and experimentally, in a paper by Mr. Hopkins, published in the fifth volume of the Transactions of the Cambridge Philosophical Society.

When the sound is caused by a current of air, as in the common flute or simple organ pipe, a tolerably satisfactory explanation of the phenomena has been given in the case of the pipe closed at one end (to which writers have confined themselves); but none whatever in that of the pipe which is open at both ends. In the former case, as in a reed of the Pan's pipe, a current of air is directed laterally over the mouth of the pipe, with a slight obliquity of direction. A condensation is therefore produced in the tube, which travels to the closed end, and is there reflected; so that by the time the condensation has travelled over twice the length of the tube (down and back again), the whole condensation, such as it was when it begun, is doubled. Hence the air in the tube has now become more powerful than the external stream, and the condensed portion begins to be discharged. This continues until not only the whole of the condensation is discharged, but also until all the velocity of the issuing particles has been destroyed; and this is not done until the effect of that velocity has produced a rarefaction in the tube. The effect of the condensation is destroyed in the same time as that in which it was produced; and hence the complete undulation belonging to the whole length of the closed tube is four times the length of the tube. Imperfect as the preceding explanation is, we know of no way of applying even so much to the open tube.

It is also to be noted that the whole of the preceding theory is but an approximation. The extremities of the open tube are not points of absolute non-condensation and non-rarefaction, but points at which the condensations and rarefactions are least and small. Similarly the nodes are not points in which the air is absolutely at rest, but points at which the motion is least. The extensions of this theory, however, important as they are in a physical point of view, are not essential to that fundamental explanation of the musical phenomena of a pipe, to which we have expressed our intention of confining ourselves in the present article.

PIPE (measure), a name given to two Hogsheads of the old wine measure; two hogsheads of ale or beer were called a butt.

PIPE-OFFICE, or more properly the Office of the Clerk of the Pipe, a very antient office in the court of Exchequer. This was formerly at Westminster, but removed to Somerset-house towards the close of the last century, where the duties of the office were performed and where the records belonging to it were kept till the abolition of the office of clerk of the pipe, and with it that of the comptroller of the pipe, by the act 3 and 4 William IV., c. 99. By that act the records which had been accumulated in the performance of the duties of this office were transferred to the custody of he king's remembrancer of the exchequer.

The business of the office had been much reduced by former acts of parliament, viz. by an act of 52 George III., which transferred the management of portions of the land-revenue of the crown to the office of woods and forests, and by acts of 1 and 2 George IV., c. 121, and 3 Geo. IV., c. 88, which transferred the duty of recording what were called the foreign accounts, or those of supplies granted by parliament, to the audit and tax offices.

Still in this office was made up year by year the record called the great roll of the pipe, or more correctly the great roll of the exchequer, in which was entered the revenue accruing to the crown in the different counties of the realm, for the charging and discharging the sheriffs and other accountants. Of this roll the deputy clerk of the pipe gives the following account in reply to the circular questions of the commissioners on the public records in 1832:—'The antient revenues here recorded were either certain or casual. The certain revenue consisted of farms, fee farms, castle-guard rents, and other rents of various kinds; the casual part was composed of fines, issues, amercements, recognizances, profits of lands and tenements, goods and chattels received into the hands of the crown on process of extents, outlawry, diem clausit extremum, and other writs and process; wards, marriages, reliefs, suits, seignories, felons' goods, deodands, and other profits casually arising to the crown by virtue of its prerogative.' (*Report of Commissioners of Public Records*, 1837, p. 198.)

Of these annual rolls there is a series commencing in the second year of King Henry II., in the year of our Lord 1155, and continued to the breaking up of the office in 1834. It is justly spoken of by Madox, the author of 'The History of the Exchequer,' as 'a most stately record,' and it is said that no country in Europe possesses any record that can be compared with it. Two only of these rolls have been lost. It approaches, as we see, in antiquity to about seventy years from the date of the preparation of the great survey of England by the Conqueror, known by the name of 'Domesday Book.' It abounds, it may be added, with valuable notices of the persons who are distinguished in English history through the whole of this period, and of the transactions of the time, recorded in every instance by a contemporaneous hand.

There is one roll of a still earlier date, which has evidently been saved by some fortunate chance when the other rolls of the same reign perished. It was formerly thought to be the roll of the 1st of Henry II; but the antiquaries of the seventeenth century, on an imperfect survey of its contents, determined that it belonged to the fifth year of King Stephen. Accordingly it has been regarded in the office as a roll of that reign, and as the roll of the 5th of Stephen it has been repeatedly quoted by historical writers, and especially by Dugdale, in his 'History of the Baronage of England,' and who, in numerous instances, has referred facts mentioned in it to the fifth year in the reign of Stephen. Madox also often quotes it as the roll of the 5th of Stephen, though he saw enough in it to lead him to refer it to the reign of Henry I. This roll has been printed and published by the late commissioners on the public records, and Mr. Hunter, one of the sub-commissioners, prefixed to it a disquisition on the year to which it belongs, in which he has shown that it is the roll of the thirty-first year of the reign of King Henry I.: thus carrying it back into the reign of one of the sons of the Conqueror, from which scarcely any national record except this has descended, and removing at once all the great historical difficulties which have arisen out of the unfortunate reference of it to the reign of his successor Stephen.

The commissioners on the public records have printed other portions of the early pipe rolls, but the volumes have not been completed.

Beside the great roll, there was a similar roll prepared by the comptroller of the pipe, which has been called the chancellor's roll. This series is far less complete than the other; and as it differed but slightly from the great roll and was never consulted, and as it appeared desirable that access should be made easier to it than could be the case while it remained in the custody of the officers of the exchequer, the late commissioners on the public records directed the removal of it to the British Museum, where the several rolls may now be consulted under the same regulations to which the other manuscripts in that depository are subjected.

The conjectures respecting the origin of the name of pipe as applied to this officer and to the great roll of the exchequer are scarcely deserving notice. One conjecture is that the rolls are so called because in form they resemble pipes another that they were transmitted through a certain pipe from one room of the exchequer to another. It may be considered as an undecided question.

PIPER, *Piper Betle*, Linn., and *Piper Siriboa*, Linn. The leaves of these two species are extensively used by the natives of the East Indies, and lately of the West, to chew along with the nut of the Areca Catechu and quick-lime, as a restorative of the powers of the stomach and promoter of digestion. It is capable however of producing, like some other species of piper, intoxicating effects, and should be used in moderation. (Curtis, *Bot. Mag.*, t. 3132.)

It is also employed, in the form of the freshly expressed juice, as a febrifuge medicine, and as an antispasmodic, especially against obstinate dry coughs.

PIPER CUBE'BA, Linn., is generally regarded as the source of the officinal cubebs; but, according to Blume, P. canicum, Rumph., which is the P. cubeba of Roxburgh, yields the greater portion of the cubebs of commerce. The fruits of both are stalked, but that of the former is larger and has more pungency than the latter. Both are common in Java, where, as in other parts of India, they are used as a grateful condiment, as common pepper is in Europe. They are also employed medicinally in the same complaints as give them repute in Europe.

The berry is small, about the size of black pepper-corns (but with a little foot-stalk, from one-third to half an inch long, hence called sometimes P. caudatum or P. pedicellosum), more or less round, of a blackish-grey or greyish-brown colour, with a thin vascular reticulated husk, which encloses a hard round oily seed. The husk has a pleasant taste; the seed a bitterish, acrid, peppery, aromatic, and camphor-like flavour.

Those which come from the islands of the Indian archipelago are the best. A sort from the Mauritius, small, or about the size of a millet-seed, are from some unknown species. The Guinea or African cubebs is the produce of Piper Afzelii.

Indian cubebs are frequently adulterated with black pepper, pimento berries, or the fruits of the Rhamnus catharticus. Genuine cubebs consist of waxy matter, two kinds of volatile oil, a peculiar resin (cubebin), balsamic resin, &c.

The volatile oil by rest deposits a camphor, which crystallizes in four-sided plates. The resin is analogous to that of copaiva, and has, like it, a peculiar influence over mucous membranes, especially those of the urino-genital organs.

PIPER LONGUM, a native of the East Indies, the female spike of which, having attached to it the dried half-ripe berries (resembling the catkin of the birch), is used in medicine. It has nearly the same chemical composition and properties as black pepper, though feebler. It is said to contain *piperin*. The root is employed by the Hindoos, but it is still weaker than the fruit.

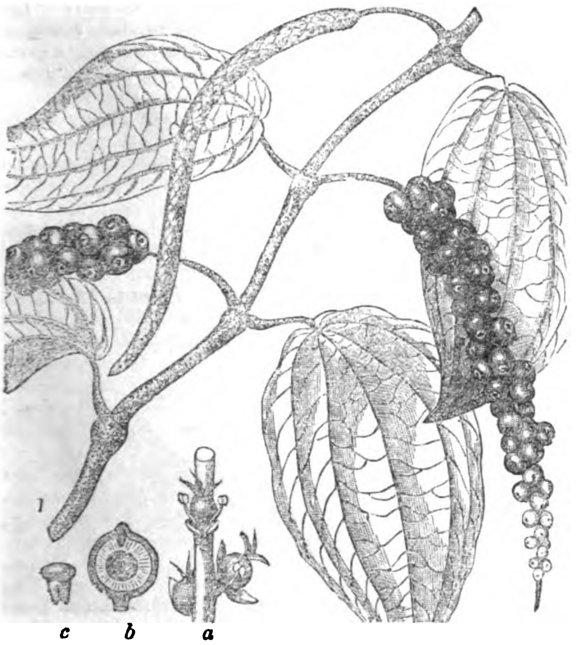
PIPER NIGRUM, Linn., a climbing plant of the East Indies, and very extensively cultivated there, the plantations stretching from the 96th to the 115th degree of E. long., and from the 5th degree of S. lat. to the 12th of N. lat., which limits comprise Sumatra, Borneo, the Malay Peninsula, and all countries to the east of the Gulf of Siam. The best pepper comes from Malabar, the least esteemed from Java and Sumatra. The plant is allowed to grow, trained to the stem of the Areca Catechu, and other trees, especially the Jack (Artocarpus) and Hyperanthera Moringa (or horse-radish-tree), four years before the fruit can be collected. The berries are gathered when yet green, before they are perfectly ripe, and quickly dried on mats, by which they turn black. When plucked too young, they speedily fall into a state of powder. These are separated from the others by sieves and winnowing. In this condition it is termed black pepper. White pepper is the same fruit freed from the outer rind: for this purpose, the ripe berries are allowed to macerate in water and the husk is removed. These are smaller, smooth, of a greyish-white colour, varying to yellow, with a less powerful odour and taste than the black.

According to the analysis of Pelletier, black pepper contains an acrid soft resin, a volatile oil, piperin, extractive, gum, bassorine, malic, and tartaric acids, salts, &c.

The odour of pepper is probably due to the volatile oil, which is not acrid; the pungent taste is most likely owing to the resin. Piperin, the exact nature of which is not ascertained, when perfectly pure, is nearly tasteless and colourless; but it is generally yellow, from the presence of some resin, to which it is most probably indebted for its virtues, as when purified by means of æther from all resin, it seems devoid of power, and the febrifuge virtues ascribed to it belong in reality to the acrid resin. Pepper is much more employed as a grateful condiment than as a medicine, and it appears to be essential to the process of digestion in hot countries. Of 50,000,000 pounds of pepper collected, one-third only goes to Europe, the greater portion being consumed by the Chinese. Its moderate use with cold raw vegetables or other substances difficult of digestion is to be approved; its employment in excess is hurtful to the liver, and a very large dose may prove fatal, not only by exciting inflammation of the stomach, but by an impression on the nervous system. Black pepper readily poisons hogs.

Whole pepper is a popular remedy against intermittent fevers, and impure piperin is used beneficially in like cases.

PIPERA'CEÆ, a small natural order of incomplete Exogens, is composed of climbing or creeping plants with alternate or opposite exstipulate leaves, jointed stems, and spiked naked flowers consisting of an ovary containing a single erect ovule, and of from two to an indefinite number of stamens. The fruit, when ripe, is more or less fleshy, indehiscent, and contains a single seed filled with albumen, on the outside of which, enclosed in a vitellus, is a minute embryo. Jussieu originally regarded these plants as members of the Urticaceous order; but afterwards separated them, in which he has been followed by all botanists. There is however some difference of opinion as to their class, some regarding them as Exogens, and others as Endogens. See Lindley's *Natural System*, ed. 2, p. 185, for an account of these opinions. The general properties of the order are aromatic, as in the peppers of the shops. [PIPER.]



1. Piper nigrum. *a*, portion of the spike of Piper aromaticum; *b*, a section of its fruit; *c*, its embryo.

PIPERIN, a peculiar principle of black pepper, first described by Oersted in 1819. It is obtained by digesting coarsely powdered pepper repeatedly in water, and the insoluble portion in alcohol. The spirituous solution evaporated to the consistence of a syrup yields crystals, which, when purified by animal charcoal, possess the following properties: they are pale straw-coloured four-sided prisms; have but little taste, are insoluble in cold water and slightly soluble in hot water; readily soluble in alcohol, less so in æther. Piperin dissolves readily in acetic acid, and by evaporation it is obtained in plumose crystals; sulphuric, nitric, and muriatic acids, when concentrated, alter its nature, and when dilute they have but little action upon it. To concentrated sulphuric acid it gives a blood-red colour; to nitric acid, a greenish-yellow, then orange, and at last a red colour; and to muriatic acid, an intense yellow.

Piperin fuses at about 212°, and when distilled it yields water, acetic acid, oil, and carburetted hydrogen gas.

Analysis according to Liebig:—Carbon, 69·78; hydrogen, 6·69; oxygen, 19·43; azote, 4·10.

PIPILLO. [TANAGRINÆ.]

PIPOWDER COURT. By the common law every owner of a fair or market [MARKET] is bound to hold a court for the decision of matters arising therein. The court being instituted principally for the convenience of the itinerant dealer, in Norman French 'pied pouldreux,' was called the court of pipowders, 'curia pedis pulverizati.' The court is held before the owner of the fair or market, or his steward, who, by 17 Edward IV., c. 2, is prohibited from entertaining any action unless the plaintiff or his attorney swear that the cause of action arose within the precincts and during the time of the same fair or market. Before that statute these courts appear to have emulated those of Westminster Hall in seeking to extend their jurisdiction; and in the preceding reign, W. Larke, the servant of a burgess coming to the parliament, was arrested in the fair of the abbot of Westminster. He was transferred by his creditor, Margerie Janyns, to the Fleet, where he remained till, by the interference of the House of Commons, he obtained his discharge. (4 Rot. Parl., 357.)

This court in its turn has been gradually encroached upon by the superior courts, and is now fallen into nearly total disuse.

PIPPI. [GIULIO ROMANO.]

PIPRA. [PIPRIDÆ; PIPRINÆ.]

PI'PRIDÆ, the name given to a family of *Dentirostres*, by Mr. Vigors, who remarks that those birds which we denominate *Chatterers*, and which form the genus *Ampelis* of Linnæus, are usually asigned a place near the family *Merulidæ;* and he confesses that, from the general affinity they appear to bear to it, he had felt, and when he wrote his valuable paper 'On the Natural Affinities that connect the orders and families of Birds' (*Linn. Trans.*, vol. xiv.), did, it is plain, still feel considerable doubt whether this was not their natural station. A strong affinity however, on the other hand, seems, he observes, to unite them with the wide-gaped *Pipræ*, and some of those other groups which, by their bill, broad and depressed at the base, appear to come in contact with the earlier divisions of the *Merulidæ*, and the extremes of the *Fissirostres*, which precede it. The general rule of placing groups in a conterminous situation, according to what appears to be the predominance of their more important characters, inclined him however to arrange the birds of which he speaks provisionally among the *Pipridæ*, at the extreme termination of the *Merulidæ*. In his view of the case at that time, the characters in which they accord with that family, and approximate the extreme groups of the preceding tribe (*Muscicapidæ*), appear to predominate. More accurate knowledge, he adds, will clear away these and similar difficulties.

Thus much Mr. Vigors observes when treating of the family *Merulidæ*. He next treats of the *Sylviadæ*, and, on leaving that family, he remarks that the true *Wrens* of the *Sylviadæ* display in their general appearance and habits so close a similarity to *Parus*, Linn., the *Titmouse* of English naturalists, that he thinks we may at once acknowledge the affinity between the latter family and that of *Pipridæ*, upon which he enters by means of the *Pari*. 'Who is there,' says Mr. Vigors, 'that has not been attracted by the interesting manners of both these familiar visitors of our domestic haunts, and, at the same time, has not been struck by their resemblance? The *penduline Titmouse, P. pendulinus*, Linn., longer and more slender in its bill than the *Pari* in general, seems to be the connecting link between the families. That species is immediately met by the genus *Tyrannulus* of M. Vieillot, which, in the name of *Roitelet Mesange*, conferred by M. Buffon on the American species of which it is composed, happily illustrates the affinity which I have ventured to point out.' Mr. Vigors further remarks that the same affinity is indicated by the antient British name of the Golden-Crested Wren, which is called in Cardiganshire *Syvigw*, that is, according to Ray, *Parus chrysocephalus;* and he proceeds to trace another affinity between the conterminous groups of *Wrens* and *Titmice* in their mode of nidification. The greater portion of both, he remarks, make their nests in holes of trees: but those groups which more nearly approach each other, viz. *Regulus, Tyrannulus*, and *Parus pendulinus*, suspend theirs from the branches, leaving the orifice at the centre, and interlacing the materials of which it is composed with corresponding ingenuity and elegance. The contiguity of this small group, he adds, to those of *Carduelis*, *Ploceus*, and *Xanthornus*, in the succeeding tribe of *Conirostres*, seems to point out the cause of this singular affinity. But though the affinity between these birds has been acknowledged by scientific as well as by common observers; the former, Mr. Vigors remarks, have generally ranked the *Pari* in a different tribe, and some indeed, he adds, have even ranked them in a different order from the *Sylviadæ*, in consequence of their more conical bill and the absence of the mandibulary notch. 'A rigid deference,' continues Mr. Vigors, 'to those particulars which form the characteristics of the conterminous subdivisions would certainly exclude the *Pari* from the present tribe of *Dentirostres*. But the nature of their food, which consists chiefly of insects, and the similarity of their habits, give them a more natural connection with the families among which I have now ventured to point out their place, than with the hard-billed and granivorous birds, where they are generally stationed. Here it may also be observed, that they form part of one of the extreme families of the tribe, and are immediately connected with a group of the preceding family of *Sylviadæ*, which passes on to the *Conirostres*, the succeeding subdivision of the order. They thus are brought into contact with the tribe to which the strength and the conical structure of their bill indicates a conformity; while, at the same time, they maintain their station among the groups where their manners and general economy would naturally place them.' Mr. Vigors then goes on to observe that the *Pari*, which thus introduce us into the present family, lead on to the more typical groups of the Linnean *Pipræ*, with which they bear an acknowledged affinity in manners and general appearance. He thinks that the genus *Pardalotus*, Vieill., which is the representative of the latter group in Australasia, appears to connect these two allied groups of the Old and New World, by exhibiting the nearly divided foot of the one and the partially curved bill of the other. Here Mr. Vigors is of opinion that *Rupicola*, Briss., and *Phibalura*, Vieillot, come in: and here, as he had already observed when speaking of the *Thrushes*, he apprehends that all those groups will be found to assemble, which, connected with *Ampelis*, Linn., are generally denominated *Berry-eaters* and *Chatterers;* such as *Bombycilla*, Briss., the true *Ampelis* of authors, *Casmarhynchus*, Temm., and *Procnias*, Ill. To these the genus *Querula* of Vieillot may, he thinks, be added. 'This group,' says Mr. Vigors in conclusion, 'the type of which is the *Muscicapa rubricollis* of Gmelin, is strongly allied by its bill to the foregoing genera, while its habits equally ally it to the family of *Muscicapidæ*, which follows. The interval between the present groups and those of the *Pari*, where we entered on the family, appears to be filled up by a race of birds peculiar to New Holland, and hitherto uncharacterised, of which the *Muscicapa pectoralis*, Lath., is the type. These, uniting many external characters at least, both of the *Berry-eaters* and *Flycatchers*, exhibit also in general appearance a considerable resemblance to the *Pari*, and will be found, I conjecture, to be the connecting bond between all these groups. The affinity between this last family of the tribe and the *Muscicapidæ*, which first met our attention as we entered it, has already been observed, when I spoke of the separation of the broad-billed *Chatterers* from the *Thrushes:* and thus, equally as in the former tribe, we may recognise the completion of a circular succession of affinities between all the families of the *Dentirostres*.'

M. Lesson, who adopts Mr. Vigors's family, makes the *Pipridæ* consist of the genera *Rupicola* and *Calyptomena* (which will be treated of in this work under the title RUPICOLINÆ), *Pipra*, *Pardalotus*, and *Pachycephala*.

Mr. Swainson does not admit the family *Pipridæ*, but he makes the *Piprinæ* a subfamily of the *Ampelidæ*. [PIPRINÆ.]

PIPRI'NÆ, Mr. Swainson's name for the *Manakins*, which he makes a subfamily of the family *Ampelidæ*, *Fruit-eaters* or *Chatterers*, and thus characterises:—

Size small. Feet lengthened, slender, weak. Bill very short: the upper mandible much curved.

Mr. Swainson is of opinion that the *Piprinæ*, called *manakins* from their diminutive size, which is seldom larger than that of a tom-tit, constitute the subtypical group of this family. 'Here again,' says Mr. Swainson, 'we find the richest tints of yellow, orange, crimson, and blue, relieving the olive-green or deep-black plumage of these elegant little birds. They are strictly American,* and chiefly occur in the deep virgin forests of the tropics, but they are much more social than the *Cotingas*. They live in little bands, are continually in motion, and feed almost entirely on the large soft berries of the different species of *Melastoma*. The nest of one species, *P. pareola*, is often built in the fork of a shrub, in such an exposed manner that the female can look all round and watch the approach of danger; we found one in such a situation in the forest of Pitanga, a single leaf of a large pepper-plant (*Piper*) forming a kind of umbrella shade over the female, which was sitting, and did not rise from her nest as we passed onward. The manakins are easily known by their weak and slender feet, of which the two outer toes are considerably united. By that singular little bird *Calyptura cristata*, the genus *Pipra* is united to that of *Pardalotus*, Vieill., or the spotted manakins of New Holland. Of a size equally diminutive, these are, nevertheless, distinctly separated from the last by their stronger bill and more pointed wings, while the feet are stronger and perfectly formed, all the toes being divided. Lewin, in his *Birds of New South Wales*, when describing one species, remarks, that it frequents high forest trees, constantly singing a short but pleasing song in passing from tree to tree. This genus, in all probability, represents that of *Dicæum* among the honeysuckers, and *Euphonia* among the tanagers. The subgenus *Metopia* seems necessary to connect *Phœnicircus* with *Pipra;* and there are one or two birds evidently belonging to this division not yet described, which, by their stronger bill, evince a tendency towards uniting with *Leiothrix*.'

Phœnicircus, *Pipra* (with its subgenus *Metopia*), *Calyptura*, and *Pardalotus*, are the genera arranged by Mr. Swainson under this subfamily.

Phœnicircus. (Sw.)

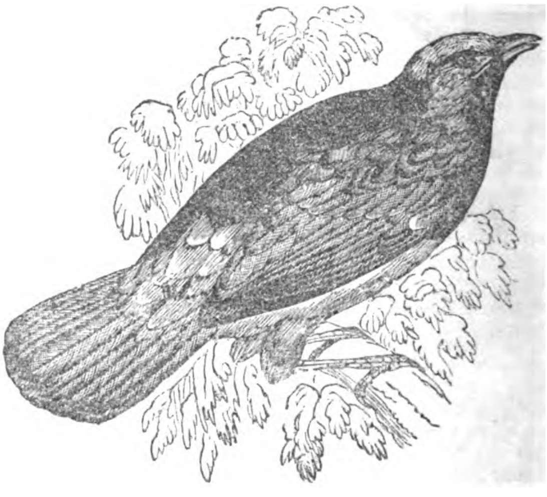
Generic Character.—Size and habit of *Ampelis*. *Bill* small, rather weak. Wings very short, convex, rounded: the three first *quills* narrow, and of equal length; the fourth much shorter, and ending in a point. *Tail* broad, even. *Feet* short, strong; *toes* syndactyle; *tarsi* feathered, on their inner side only, as far as the toes; *claws* strong, curved. (Sw.)

Example, *Phœnicircus Carnifex*. (*Ampelis Carnifex*, Linn.)

Description.—Fire-red, with a bright red cap; back red-brown; breast blood-red; tail-feathers purple, terminated by ruddy-black. *Female* reddish; abdomen ochraceous; front reddish.

The Caraibs designate this magnificent bird by the names *Arara* and *Apira*.

Localities.—Brazil, Guiana, Surinam.



Phœnicircus Carnifex.

Pipra. (Linn.)

Generic Character.—Size very small. *Bill* weak: the upper mandible bent over the lower, which is flattened and nearly straight; notch small. *Wings* more or less rounded. *Tail* short, even. *Toes* syndactyle.

Examples, *Pipra strigilata*, and *Pipra Aureola*.

Description of Pipra strigilata.—(*Male.*)—Size of a wren; a patch or cap of fire-colour covers the head; all the upper part of the body uniform grass-green; all the lower parts yellow striated with brown; bill brownish; feet yellowish.

---

* But see *Pardalotus*, post, p. 179.

Female.—Not differing from the male, except in the absence of the red cap on the head.

Locality.—Brazil.

Description of Pipra Aureola.—Red; back, wings, and tail black; throat yellow.

Locality.—Guiana.

Pipra Aureola.

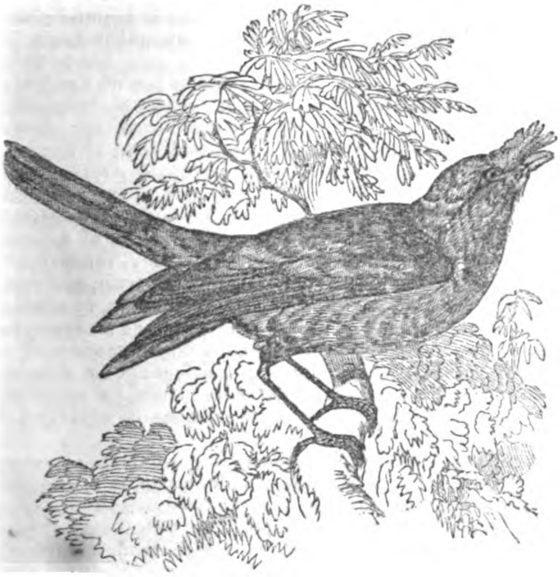
Metopia. (Sw.)

Generic Character.—*Front* with an elevated compressed crest. *Wings* lengthened, very broad. *Tail* broad, lengthened, rounded. (Sw.)

Example, *Metopia galeata.* (*Pipra galeata*, Licht.)

Description.—Black. Frontal crest, directed forwards over the culmen of the bill, rich crimson, which colour is also continued over the head and back of the neck; feet and legs reddish brown.

Locality.—Brazil.



Metopia Galeata.

Calyptura. (Sw.)

Generic Character.—*Bill* short, strong, robust, shrike-like; the sides somewhat gibbous; the notch deep and tooth-like. Under mandible strong. *Wings* short, rounded. *Tail* remarkably small, almost concealed. *Feet* lengthened, slender, toes syndactyle. (Sw.)

Example, *Calyptura cristata.*

Description.—Crown red; upper parts brownish or olivaceous green; rump yellow; throat and breast yellowish; abdomen brighter yellow; feet and legs black.

N.B. The hidden part of the feathers is obscure lead-colour, the ends of them only giving the prevailing colour. When the plumage is blown aside or disturbed, the lead-colour appears.

Locality.—Brazil.

Calyptura Cristata.

Pardalotus. (Vieill.)

Generic Character.—*Bill* as in *Calyptura.* *Wings* long, pointed; the three first quills of equal length. *Tail* short, even. *Feet* strong; lateral toes free and equal. (Sw.)

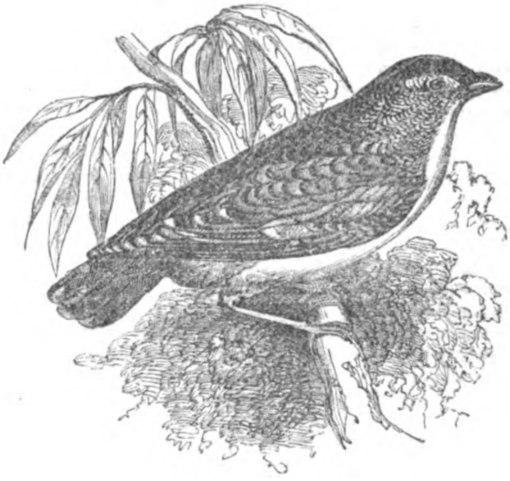
Example, *Pardalotus punctatus.*

Description.—(*Male.*)—Grey above, undulated with yellow; head and wings black, dotted with white; a white line above the eye; rump fire-red; abdomen whitish; throat yellow.

The *female* has the head dotted with yellow points.

Locality.—Australia.

Habits, &c.—Mr. Caley states that this species is called *Diamond Bird* by the settlers, from the spots on its body. He adds that it is reckoned a valuable bird on account of its skin, that it is not very plentifully met with, and that it inhabits both forest-land and brushes, at least he had seen it in both. (*Description of the Australian Birds in the Collection of the Linnæan Society*, Vigors and Horsfield, in *Linn. Trans.*, vol. xv.)



Pardalotus punctatus.

Mr. G. R. Gray makes the *Piprinæ* the second subfamily of the *Ampelidæ*, *Pachycephalinæ* being the first; and he arranges under it the following genera:—

1. *Phœnicircus*, Sw. (*Pipra*, Wagl., *Ampelis*, Linn., *Querula*, Cuv.). 2. *Metopia*, Sw. (*Pipra*, Licht.) 3. *Pipreola*, Sw. 4. *Pipra*, Linn. (*Manacus*, Briss.). 5. *Pipracidea*, Sw. 6. *Iodopleura*, Sw. (*Pardalotus*, Less.). 7. *Calyptura*, Sw. (*Pardalotus*, Vieill., *Regulus*, Licht.).

PIQUET, a corps of troops detached from the main body of an army, when in position or in cantonments, and disposed about it in parties so as to form a chain of outposts for its security.

As an army depends for its safety upon timely notice being obtained of the movements of the enemy, in order that it may prepare itself to repel an attack, it is of the utmost importance that the advanced posts should be disposed in such a manner that they may mutually support one another, and that none of them may be cut off by parties of the enemy passing unobserved between them. The chain must of course entirely surround the position, unless the latter should in any part be secured by rivers or by some other obstacles which it may be impossible for the enemy to pass or turn. The nature of the ground determines the class of troops which should be employed; but in general both cavalry and light infantry are appointed together for the outpost duty. In an open country the former may be numerous, but in one much enclosed or abounding with obstructions, the latter alone can act efficiently.

In the French service, the term *piquet* is applied not to the whole corps of troops at the outposts, but to the particular bodies of cavalry or infantry, from 100 to 500 strong, which are stationed at intervals from each other at about half a league from the army which they cover. Detachments from these, constituting what are called the main guards or rallying posts, and varying in strength from 20 to 100 men, are sent forward about half a mile further; and at about an equal distance beyond them are established posts of observation, consisting of parties of from 5 to 20 men. From the last are sent out the vedettes, as they are called, if of cavalry, or the sentinels, if of infantry, in the proportion of one man for every four or five of their number; and these, who are placed at the distance of 200 or 300 yards in advance of the posts of observation, constitute the outer circumference of the chain.

A nearly similar method of forming the chain of advanced posts is followed by the armies of all nations, when in the field; and it is evident that, by such a system, any movement of the enemy must be known in time to allow the necessary measures to be taken for frustrating its object.

The several corps or parties of troops employed on piquet duty are commonly posted on elevated and advanced points of ground, in order that they may be able to observe the enemy; and particularly that they may command the roads or passes by which he may advance towards the position occupied by the army. They generally take possession of villages or isolated buildings, if such there be; otherwise, when liable to be annoyed by the enemy's parties, they obtain cover from walls or embankments, or from small breastworks thrown up for the purpose. The lines of approach to the position should be blocked up by abatis, or intersected by trenches, so that the progress along them may be impeded; and some of them should, if possible, be rendered entirely impassable, in order to diminish the number of points to be guarded. The advanced corps should also have the means of succouring each other when necessary, and of retiring when in danger of being overpowered: for these purposes they are placed where the ground is favourable for communication or retreat. If for any reason a party should be stationed where this is not the case, routes must be formed by levelling walls, cutting openings through woods, laying bridges over streams, or by any other method which may be found convenient.

The outlying vedettes or sentries should be placed in situations where they may be able to see all the ground from one to another; and patroles of cavalry should be constantly moving between these and the interior posts. It may be added that patroles intended to act offensively are frequently employed in reconnoitring the ground leading to the enemy's position, in endeavouring to surprise his sentinels, or in skirmishing with the troops in his outposts.

The principal corps which form the chain are expected to defend for a time the posts which they occupy; and, on this account, they are frequently provided with a certain number of pieces of artillery, which they so dispose, under cover of an epaulement, that the fire may be directed along the line by which the enemy must advance. The smaller parties however are instructed to resist no longer than may be necessary to enable them to ascertain the force of the enemy and the direction in which he is moving. Concerning these points, notice must immediately be sent to the nearest officer in command of the outposts; for which purpose, and also for the general transmission of orders or reports, a certain number of dragoons are joined to each post of infantry. On establishing the chain, the several parties or individuals should be informed at what particular points they are to rally in the event of being driven in, and by what routes they are to arrive at those points.

At night the outlying parties are generally reinforced, or are made to take less advanced positions; and other parties are always kept in readiness to increase their strength still further if necessary. In the event of an enemy appearing, the sentinels, having given the alarm by discharging their muskets, retreat to the nearest posts; and these, if compelled, retire to the main guards, continually skirmishing with the enemy in order to retard his progress, yet taking care to avoid being cut off. By the delay thus occasioned, time is afforded for ascertaining the force of the enemy, and, if necessary, for drawing out the army in order of battle to receive his attack.

PIRACY, PIRATE (immediately from the Latin *pirata*, and remotely from the Greek *πειρατής*, which had the same signification as our word pirate). The crime of piracy, or robbery and depredation on the high seas, is an offence against the universal law of society; a pirate being, as Blackstone expresses it, 'hostis humani generis' (4 Bl., 70). 'With professed pirates,' Lord Stowell observes (2 Dods., 244), 'there is no state of peace. They are the enemies of every country, and at all times; and therefore are universally subject to the extreme rights of war.'

Molloy, an antient writer on maritime law, but whose doctrine it would be dangerous to adopt in these days, says, 'If a piracy be attempted on the ocean and the pirates are overcome, the captors may immediately punish them with death, and not be obliged to bring them into any port, provided this occurs in places where no legal judgment can be obtained. So likewise if a ship be assaulted by pirates, and in the attempt they are subdued and taken, and carried into the next port, if the judge openly rejects their trial, or the captors cannot wait till judgment shall be given without certain peril and loss, they may do justice on them themselves without further delay or attendance.' (Molloy, *De Jure Maritimo*, chap. iv., sect. 12, 13.)

'There is said to be a fashion in crimes; and piracy, at least in its simple and original form, is no longer in vogue. There was a time when the spirit of buccaneering approached in some degree to the spirit of chivalry in point of adventure; and the practice of it, particularly with respect to the commerce and navigation and coasts of the Spanish American colonies, was thought to reflect no dishonour upon distinguished Englishmen who engaged in it. The grave judge (Scaliger) observes, in a strain rather of doubtful compliment, "Nulli melius piraticam exercent quàm Angli."' (Lord Stowell, 2 Dods., 374.)

The offence of piracy, by the common law of England, consists in committing those acts of robbery and depredation upon the high seas, which, if committed upon land, would have amounted to felony there. (4 Black., 72.)

By statute some other offences are made piracy, as by stat. 11 and 12 Will. III., c. 7, if any natural-born subject commits any act of hostility upon the high seas against others of his majesty's subjects, under colour of a commission from any foreign power, or if any commander or other sea-faring person shall betray his trust, and run away with any ship, boat, ordnance, ammunition, or goods; or if he yields them up voluntarily to a pirate, or conspires to do these acts; or if any person assaults the commander of a vessel to hinder him from fighting in defence of his ship, or confines him, or makes or endeavours to make a revolt on board, he shall for each of these offences be adjudged a pirate.

By the stat. 8 Geo. I., c. 24, the trading with known pirates, or furnishing them with stores or ammunition, or fitting out any vessel for that purpose, or in anywise consulting, combining, confederating, or corresponding with them; or the forcibly boarding any merchant vessel, though without seizing or carrying her off, and destroying or throwing any of the goods overboard, shall be deemed piracy. (See further on this point, 4 Blacks., 72, 269; and Abbott, *On Shipping*, 140, 141, 142, 239.) Lastly, the stat. 5 Geo. IV., c. 113, sec. 9, makes the dealing in slaves on the high seas by any of his majesty's subjects piracy, and subjects the guilty party to the penalty of death.

Persons guilty of piracy were formerly tried before the judge of the admiralty court according to the rules of the civil law, but this was altered by the stat. 28 Henry VIII., c. 15, which enacted that the trial should be before commissioners of oyer and terminer, and that the course of the proceedings should be according to the law of the land. Further provision was made with respect to the trial of offences on the high seas by the statutes 39 Geo. III., c. 15; 43 Geo. III., c. 113; 46 Geo. III., c. 54; and now, by the stat. 4 and 5 Will. IV., c. 36, sec. 22, the trial of offences committed on the high seas is in the Central Criminal Court.

PIRÆUS. [ATHENS.]

PIRANE'SI, GIOVANNI BATTISTA, born at Venice, in 1720, was one of the most distinguished artists of the last century, and in his own peculiar walk unrivalled. At the age of eighteen, he was sent by his father (who was a mason) to study architecture at Rome; to which he devoted himself with such enthusiasm as to thwart his parent's intentions, for on being summoned to return home, he refused, observing that Rome with its monuments was the adopted land of his affections—the birth-place of his talent. On this, his father withdrew his allowance, but instead of being tamed into submission, or at all discouraged, the young artist soon after (in 1741) brought out his first work on triumphal arches, bridges, and other architectural remains of antiquity. This production instantly established his reputation, the engravings being treated with such mastery, and being altogether so decidedly superior to any former representations of similar subjects, as to make an epoch in chalcography and architectural delineation; which latter had till then been almost uniformly very coarse, tasteless, and insipid, and nowhere more so than in Italy itself. With occasional exaggeration of chiaroscuro and effect, there is great vigour of execution in Piranesi's productions, which may partly be ascribed to his singular manner of working, it being his usual practice to draw his subject at once upon the plate itself, and complete it almost entirely by etching in aquafortis, with very little assistance from the graver. Hence his works are marked by a freedom and spirit that can otherwise hardly be preserved. The same circumstance also accounts for that astonishing rapidity of execution which enabled him to produce, within less than forty years, about two thousand engravings, most of them of very large dimensions and full of detail.

It is true he was not wholly without help from other hands, for all his children (three sons and two daughters) were brought up by him to assist him in his labours; and he had likewise several pupils, among others Piroli, a name of some note. Still such aid must have been comparatively inconsiderable, since it is evident from the peculiar manner and spirit which pervade his works, and which have never been caught by any of his scholars, that all his plates must have been executed chiefly by his own hand. The following is a list of his principal works:—'Architectura Romana,' 208 plates, 4 vols., atlas folio; 'Fasti Consulares Triumphalesque Romanorum;' 'Antichita d'Albano,' 35 plates; 'Campus Martius,' &c., 54 plates; 'Magnificenza dei Romani,' 44 plates; 'Vedute di Roma,' 2 vols., 130 plates of modern buildings at Rome; 'Collection of Candelabra, Vases,' &c.; 'Collection of Chimney-pieces,' a series of most splendid designs; 'Carceri d'Invenzione,' 16 plates, filled with exceedingly wild but most picturesque conceptions; 'A Collection of Antient Statues and Busts,' 350 subjects; 'The Trajan and Antonine Columns;' 'Antiquities of Herculaneum and Pompeii.' A complete set of his works (comprising many not here enumerated) amounts to no fewer than twenty-nine folio volumes, many of which are of unusually large dimensions, some of them being on double elephant paper, and the plates opening to ten feet in length. Their contents afford an almost inexhaustible mine of antiquity, both as regards architecture and sculpture; and indeed his 'Magnificenza' alone, containing as it does many specimens and fragments of antient architecture till then little known, and so different from the usual routine examples of the orders, would alone have sufficed for his fame. Several of these, and other specimens of antient art engraved by him, such as vases, candelabra, &c., have been since copied in later works, yet even where they have been correctly and tastefully delineated, they are immeasurably inferior to the same subjects as touched by Piranesi.

In addition to his other numerous and extensive labours, he executed one or two of the plates in the 'Works' of Robert Adam, the English architect, where their superiority to the rest manifests itself very strongly. Piranesi did not execute much as a practical architect: the wonder is, that he should have found time to accept any professional engagements of the kind. Nevertheless he did so, and among the churches which he was employed by Clement XIII. to repair or rebuild, are those of Santa Maria del Popolo and the priory of Malta. It is in this last-mentioned edifice that a monument by Angolini, a life-sized statue of him, has been erected to his memory; an engraving from which is contained in the second volume of the 'Library of the Fine Arts,' a publication containing many valuable papers, and to which we are indebted for some of the particulars above given. Piranesi died at Rome, November 9, 1778.

PIRATE. [PIRACY.]

PIRE'NA. [MELANIANS; MELANOPSIS, vol. xv, pp. 76, 77.]

PIRIME'LA, Dr. Leach's name for a genus of *Crabs*, placed by M. Milne Edwards among the *Canceriens Arqués*, or those crabs which have no clypeiform prolongation on the sides of the carapace, which is much wider than it is long, arched in front, and strongly truncated on each side posteriorly.

M. Milne Edwards observes, in common with most other writers on the *Crustacea*, that the general form of *Pirimela* differs but little from that of many *Cancerians;* but he adds, that in other points it is far separated from them.

Carapace regularly arched on its anterior moiety, and strongly truncated on each side of its posterior moiety; much wider than it is long; convex, and strongly bossed. The *front* narrow and armed with three pointed teeth. The latero-anterior borders are directed very obliquely backwards and outwards, and are armed with four compressed and triangular teeth. The *orbits* present two teeth and two fissures above, a sharp tooth at the external angle, and a fourth at the internal and inferior angle. The *internal antennæ* are bent back longitudinally, as in the *Platycarcini.* The *external antennæ* are very long, but their first joint, which is lodged in a gap of the orbitary angle, is very short, and is not prolonged nearly so far as the basilary joint of the internal antenna; the moveable stem of these appendages springs consequently in the internal orbitary canthus, as in *Xantho,* &c. The *external jaw-feet,* instead of fitting into the buccal frame, as in all the preceding genera (according to the arrangement of M. Milne Edwards), advance upon the *epistome,* and instead of carrying the succeeding joint at the anterior and internal angle of their third joint, they give insertion to it towards the anterior third of that joint. The *sternal plastron* presents the same disposition as in the *Crabs,* &c.; its length only exceeds its width by one half, and its median suture occupies its three last segments. The anterior feet are small and compressed; the succeeding feet present nothing remarkable. The abdomen of the male is only composed of five joints.

Example, *Pirimela denticulata.*

Description.—Carapace smooth, but strongly bossed on the stomachal, genital, and branchial regions, and concave on the hepatic regions; latero-anterior borders delicate and not reaching beyond the level of the middle of the genital region. Pincers furnished with a small crest above, and with one or two carinated lines on their external surface. Length about six lines; colour greenish.

Localities.—Coasts of Europe, England and France

Pirimela denticulata.

PIRMASENS is a well-built fortified town in the Bavarian province of the Rhine. It was a place of small importance till Lewis IX., landgrave of Hesse-Darmstadt, chose it for his residence. In his time it had 9000 inhabitants; but he died in 1790, and the wars of the French revolution soon afterwards breaking out, the town greatly declined, and after having several times changed masters in the various cessions of territory that ensued, was at length annexed to Bavaria. It has now about 5000 inhabitants. The palace, the town-hall, the Lutheran school, and the Lutheran and Calvinist churches are accounted handsome buildings. There is also a large building for exercising troops in bad weather. There are some vinegar-manufactories, and musical instruments are made. In the year 1793 the duke of Brunswick obtained an advantage over the French near this town. Pirmasens is 13 miles east-south-east of Deux Ponts, and 35 west of Spire.

PIRNA, a town in the circle of Meissen, in the kingdom of Saxony, situated in a beautiful part of the country on the left bank of the Elbe, 9 miles south-east of Dresden. Most of the houses are built of stone from the celebrated quarries near the town. The principal public buildings are the town-hall, the great church, which is one of the finest specimens of Gothic architecture in the kingdom, with painted glass windows, and the convent church, which belonged to the Dominican convent founded in 1301. The lyceum has been converted into a school. A Roman Catholic school was founded in 1822, and the Roman Catholic church of St. Kunigunda was consecrated in 1823. An admirable orphan asylum was founded in 1813; and in 1830 a new school-house was built, which is one of the handsomest edifices of the kind in Saxony. On a high rock near the town, called the Sonnenstein, there was formerly a strong fortress, which was dismantled by the Prussians in the Seven Years' war. It was afterwards fitted up as a lunatic asylum, but in 1813 Napoleon expelled the patients, and again fortified it. However the establishment was restored in 1814, on an admirable plan, which may serve as a model for similar institutions. There are flourishing manufactures of cotton, linen, woollen cloths, stockings, hats, leather, ironmongery, starch, &c. Calico-printing is carried on to a great extent. The inhabitants have a considerable trade in their own manufactures, and in the natural productions of the country, among which the Pirna sandstone holds an important place. There are numerous quarries in the adjacent country, which furnish three sorts of stone; the first is best suited for grindstones, the second for millstones, and the third for the use of the sculptor and statuary: the last is exported to England. Pirna has 5560 inhabitants. (Hassel, *Handbuch;* Stein, *Geographisches Lexicon;* Engelhardt, *Das Königreich Sachsen*, seventh edition, by W. E. A. v. Schlieben.)

PIRO'N, ALEXIS, born at Dijon, in 1689, studied the law, took his degrees, and practised as an advocate in his native town, but he afterwards forsook the bar, and lived for a time in gay and dissipated society. Being distressed in his circumstances, he repaired to Paris, and employed himself as a copyist, and afterwards wrote for the stage. He produced several light comedies and farces, which succeeded very well, but he failed in his attempt to write tragedy. At fifty years of age he composed his drama 'La Métromanie,' the best of his works, which established his reputation as a writer. He had been himself in his youth seized by a kind of mania for writing verse, and was therefore a competent judge on the subject. Piron had much ready wit and a great facility for repartee, and his epigrams were very celebrated in his time. He wrote also Tales, Odes, and other light poetry, most of them grossly licentious, according to the prevailing taste of his age, which was that of the reign of Louis XV. He may be considered as a representative of his time and country, witty, thoughtless, and licentious. He had however some attractive personal qualities, and he found friends among a higher order of men. Montesquieu obtained for Piron a pension from the king of 1000 livres; the count of Livry, Maurepas, the duke of Nevers, and other noblemen also patronised him. He married at a mature age a woman of mature years, and lived very happy with her till her death. Piron's sight was very weak, and a fall which he had in the park of the count of Livry hastened his death in 1773. His works were collected without discrimination, and published by Rigoley de Juvigny, 7 vols. 8vo. Piron however, before his death, had expressed his regret at the publication of some of his more obscene odes, which had proved a bar to his being received among the members of the Académie Française, an honour which he had sought, although he affected to disdain it in his writings. The following is his epitaph, written by himself:—

'Ci gît Piron, qui ne fut rien
Pas même Académicien.

PISA. The *Compartimento* or *Province of Pisa*, one of the administrative divisions of Tuscany, is bounded on the north by the duchy of Lucca, on the east by the province of Florence, on the west by the sea, and on the south by the Compartimento of Grosseto, which has been detached from the province of Siena. [SIENA.] The province of Pisa comprises: 1, The lower part of the basin of the Arno, with a small part of that of the Serchio. 2, A hilly range, called Montenero, or Monti Livornesi, which bounds the basin of the Arno on the south, and runs close to the sea south-east of Livorno. 3, The basin of the Cecina, south of the hills just mentioned. The river Cecina rises in the range of high lands, between 1000 and 1500 feet high, which divides the Maremma, or maritime lowlands, from the valley of the Ombrone in the province of Siena, and, after a tortuous course of about 40 miles in a western direction, enters the sea by two mouths in the gulf of Vada, 22 miles south-east of Livorno. 4, A strip of land south of the mouths of the Cecina, and extending along the sea-coast and between that and the hills for about 12 miles, as far as the Torre S. Vincenzo. South of this point is the district of Piombino, which formerly made part of the province of Pisa, but has of late years been annexed to the Compartimento of Grosseto. To the east of Piombino is the district of Campiglia, in the valley of the Cornia, which has likewise been detached from Pisa and annexed to Grosseto. 5, The island of Elba, which is attached to the administrative province of Pisa. 6, Several detached districts, or 'enclaves,' as the French style them, situated to the north between the territories of Lucca, Modena, and Parma, but which belonged of old to the grand-duchy of Tuscany, and are appurtenances to the administrative province of Pisa. These divisions are: Barga, in the valley of the upper Serchio, between the states of Lucca and Modena [GARFAGNANA]; Bagnone and Fivizzano, in the valley of the Aulella, an affluent of the Magra at the foot of the Apennines, in the region called Lunigiana, which is now divided between Modena, Tuscany, and Sardinia [MODENA, DUCHY OF]; Pontremoli, still farther north, near the sources of the Magra, and at the foot of the Apennines of La Cisa, which divide it from the valley of the Taro in the state of Parma. Pontremoli is a small town with a castle, which is mentioned in the history of the middle ages as commanding an important pass from the plain of Lombardy to the shores of the Mediterranean. A road leads from Parma by Pontremoli to Sarzana. Lastly, the district of Pietrasanta, which lies along the sea-coast between the territories of Lucca and of Massa and Carrara, belongs also to the province of Pisa. It stretches from the sea to the foot of the Carrara Mountains, or Alpe Apuana, and is chiefly noted for its marble quarries at Serravezza, which are of the same description as those of Carrara. The area of the whole province of Pisa is about 1350 square miles, and the population in 1835 was 326,570. (Serristori, *Statistica d' Italia.*) It is divided into 15 districts, containing in all 53 communes. The districts are: Pisa, Livorno, Rosignano, Guardistallo, Pomarance, Peccioli, Pontedera, Lari, Vico Pisano, Barga, Bagnone, Fivizzano, Pontremoli, Pietrasanta, and Portoferrajo, or Elba. The principal towns are: PISA, LIVORNO, and Portoferrajo. [ELBA.]

PISA, one of the principal towns of Tuscany, and the handsomest next to Florence, is situated in a plain, through which flows the Arno, forty-five miles west of Florence, thirteen miles north by east of Livorno, and about four miles from the sea-coast. The town is divided by the river into two nearly equal parts, connected by three bridges, one of which is of marble. The circumference of the walls is about six miles; the quays along the Arno and several other streets are wide, well-paved, and lined with handsome buildings, but the town has an appearance of loneliness, and the grass grows in many of the streets. The population, which once exceeded 100,000, is now hardly 20,000. The four most remarkable buildings of Pisa, the cathedral, baptistery, belfry, and Campo Santo, are grouped near one another in a vast open place at the western extremity of the town. The duomo, or cathedral, begun in the eleventh century, is a splendid Gothic structure, cased externally with marble of various colours, and ornamented with numerous relievos, inscriptions, and columns of various sizes, put together without much taste. The interior of the church is rather dark, the light coming in through small windows of painted glass; the nave is divided from the rest of the church by fine columns of granite; and the three bronze gates of the façade are ornamented with figures.

The dome is one of the earliest constructions of the kind among the churches of Italy, though posterior to those of S. Vitale at Ravenna and St. Mark at Venice. The pulpit is enriched with valuable sculptures by Giovanni di Pisa; other statues and sculptures by the same, and by Giovanni da Bologna and other artists, are in various parts of the church. The paintings are by Andrea del Sarto, Razzi, called Il Sodoma, Salimbeni, Salvator Rosa, Roselli, Luti, Sorri, Riminaldi, Sogliani, and other masters. The pavement is of marble of various colours This magnificent temple was erected by the architect and mechanician Buschetto and his successor Rainaldo.

The baptistery, detached from the church, is round, and entirely cased with marble. It was built about the middle of the twelfth century, by the architect Diotisalvi of Pisa. It is ornamented by numerous sculptures; the pulpit in particular is considered a masterpiece of Nicola Pisano. [BAPTISTERY.]

The belfry is a round tower, likewise cased with marble, 190 feet high, which deviates from the perpendicular line about fourteen feet. It was erected in the latter part of the twelfth century, by the architects William of Innspruck and Bonanno of Pisa. From the summit there is a splendid view of the plain, the surrounding mountains, and the sea.

The Campo Santo, or cemetery, constructed in the thirteenth century, by Giovanni di Pisa, is a long parallelogram, 430 feet in length, with an arcade or cloister running all round the interior, the walls of which are covered with fresco paintings, chiefly by Giotto, Orgagna, and Memmi. The paintings are for the most part greatly damaged, and some are entirely obliterated. [NICOLA DI PISA.] A series of engravings of the paintings has been published. (Rosini, *Pitture del Campo Santo di Pisa, con l'indicazione dei Monumenti di Belle Arti colà raccolti*, 1816.)

Several antient sculptures and other remains of antiquity are deposited in the Campo Santo. Among the tombs is that of the Countess Beatrice, the mother of Matilda, of Algarotti, Pignotti, and of the celebrated surgeon and professor Vacca, which last is the work of Thorwaldsen.

The other remarkable buildings of Pisa are—1, the church of S. Stefano, belonging to the military order of that name, which was founded in 1561, by the grand-duke Cosmo, for the purpose of crusading against the Barbary pirates; 2, that of S. Frediano, which is rich in paintings; 3, S. Nicola, with a handsome belfry, the work of Nicola Pisano; 4, S. Michele in Borgo contains the monument of Guido Grandi, a celebrated mathematician and antiquarian, and contemporary of Newton, whose MSS., in forty-four volumes, are in the university library; 5, S. Maria della Spina, a handsome church, with good paintings and sculptures. There are many other churches besides these. 6, The palaces of Lanfranchi and Lanfreducci; 7, the Torre della Fame, in which Ugolino and his children were starved to death; it now forms part of a structure called Palazzo dell' Orologio, on the Piazza dei Cavalieri; 8, the university buildings, the library, observatory, and botanical garden; 9, the great hospital; 10, the Loggia, or old Exchange.

The Certosa, or Carthusian convent and church, is in a pleasant situation, about two miles east of Pisa. The vast farm and forest of S. Roisore, belonging to the grand-duke, three miles from Pisa, near the sea, is chiefly remarkable for the camels, about eighty in number, the original stock of which were brought to this spot in the time of the Crusades. The mineral baths, called di S. Giuliano, four miles from Pisa, at the foot of a mountain, have been restored on the remains of antient thermæ, which were frequented in the middle ages by the countess Matilda. The present buildings are of the last century. They are not so much frequented as they used to be, people resorting in preference to the baths of Lucca, the situation of which is more agreeable and healthy, especially in summer, when the air of Pisa and the neighbouring plain is not considered wholesome, though it is not so deleterious as it once was, owing to the drainings that have been made, and the improvements effected in cultivation of late years. During the winter the climate of Pisa is extremely mild though rainy, and is well suited to persons with weak lungs.

History of Pisa.—The origin of Pisa was a matter of doubt even in the time of Cato, who acknowledged that he could not ascertain who were its original inhabitants before it came into the possession of the Etruscans. (Servius, x. 179.) Strabo and Pliny give it a Greek origin, and consider it to be a colony of Pisa in Elis, and Virgil (*Æneid*, x.) adopts the same tradition. Lycophron pretends that Pisa was taken by the Tyrrhenians from the original Ligurian inhabitants. Pisa was on the border between Etruria and the country of the Ligurians, and was probably colonised by the Etruscans when they extended their dominion from the Arno to the Macra. It is not reckoned among the twelve principal towns of the Etruscan confederation. It underwent the same vicissitudes as the rest of Etruria, and became subject to Rome about the middle of the fifth century of Rome, retaining, like most Etruscan towns, its municipal form of government. Livy (xl. 43) mentions that a Latin colony was sent to Pisa, at the request of the citizens, who offered a part of their territory to the colonists about 179 B.C. Nothing more is said concerning Pisa in Roman history, but we find that it had bishops at the beginning of the fourth century. Pisa passed successively under the dominion of the various conquerors of Italy, the Goths, the Longobards, and the Carlovingians. Under the last it governed itself, like most other Italian towns, as an independent community under a nominal allegiance to the emperors and their great feudatories the counts or marquises of Tuscany. In A.D. 874, the Pisans appeared in arms against the Saracen pirates from Africa, who were scouring the Mediterranean, and who, after having plundered the Roman coast, and made many prisoners, landed at S. Pietro in Grado, about three miles from Pisa. The Pisans attacked them by land whilst their galleys came out to cut off the retreat of the Saracens, who escaped, leaving their prisoners behind them, whom the Pisans restored to Rome. In the year 926, Hugo of Provence came to Pisa, where he received the homage of the great feudatories as king of Italy. In 965, Otho I., on his return from Rome, stopped at Pisa, and was so pleased with his reception that he granted various privileges to the town, and several noblemen of his retinue were so delighted with the country that they asked his leave to remain and settle there. This was the origin of seven noble families, which afterwards figured in the history of Pisa, namely, Casamatti, Orlandi, Ripafratti, Visconti, Verchionesi, Gusmani, and Duodi. From that time Pisa was considered one of the Italian cities most attached to the emperors. About A.D. 1003 the Pisans sent their galleys to the coast of Syria, against the Seljuk Turks, who had invaded the country, and who vexed the Christians of Palestine.

In the following year began the long struggle between Pisa and Muscet, the Moorish king of Sardinia, which ended in the final conquest of that island by the united Pisans and Genoese, in the year 1022, after which the Pisans divided Sardinia into four provinces, or giudicati, namely, Cagliari, Torre or Sassari, Arborea, and Gallura, to which they appointed giudici, or governors, from the principal families of Pisa, who in the course of time became nearly independent. At this period Pisa was a republic, having its annual consuls, but it appears that the bishop had also a considerable share in the administration. The territory of Pisa extended on the side of Florence as far as Empoli, and along the coast to the south-east as far as Piombino. Lucca bordered it on the north, and frequent dissensions arose between it and Pisa. The harbour of Pisa was formed by a bay which is now filled up, at a place called Calambrone. [ARNO.] In the year 1030, the Pisans sent a fleet of 50 galleys to Carthage (so say the chroniclers, but perhaps they mean Porto Favina), and took the town from the Saracens, and in 1038 they likewise took possession of the island of Lipari. In the year 1050, the Moors of Barbary again invaded Sardinia, but the Pisans sent a large armament, and drove them away. The Pisans at the same time subjected, at least in part, the island of Corsica, and in 1089 or 1091, Pope Urban II. made a grant to the Pisans of the whole island as a fief of the Apostolic See. (Tronci, *Memorie di Pisa.*) In 1062, Pisa sent assistance to Robert Guiscard, the Norman duke of Apulia, against the Saracens. In 1063, the Pisans sailed to Palermo, which was occupied by the Saracens, and, after a sharp engagement, they entered the harbour, and carried away the shipping, with a rich booty, part of which was employed in building their splendid cathedral. The Pisans however did not retain possession of Palermo, which soon after fell, with the rest of Sicily, into the hands of the Normans. About the year 1070 began the wars between Genoa and Pisa, which continued, with various interruptions, for more than two centuries, and ended in the downfall of Pisa. Commercial jealousy, and the possession of Corsica, which the Genoese aimed at, were the causes of the war. The respective claims of the Genoese and Pisans upon Corsica have been a matter of much historical controversy. (Tanucci, *Dissertazione del Dominio Antico dei Pisani sulla Corsica;* Flaminio del Borgo, *Dissertazioni Pisane; Note* agli 'Annali Genovesi' di Caffaro; Manno, *Istoria della Sardegna.*) In 1088, the two states, having made peace, joined their fleets, and, sailing to the coast of Barbary, took the town of Mahadiah, which is also called Africa by the chroniclers, on the eastern coast of Tunis, and which was then the capital of a considerable Saracen state. They obliged the king to pay a large sum of money, to release all his Christian slaves, and to promise never more to cruise with his privateers in the Italian seas. About this time the Countess Matilda made several important donations of lands and castles to the see of Pisa, the diplomas of which are given by Tronci. Countess Beatrice, Matilda's mother, died at Pisa, and her cenotaph is still seen outside of the cathedral. Donizo, in his Life of Matilda, represents Pisa as a great and flourishing emporium, whither ships and merchants from all parts of the Mediterranean resorted:

> 'Qui pergit Pisas, videt illic monstra marina;
> Hæc urbs Paganis, Turchis, Lybicis, quoque Parthis
> Sordida; Caldæi sua lustrant littora tetri.'

It was in this period of their prosperity that the Pisans completed their splendid monuments of art, the cathedral, the belfry, baptistery, and Campo Santo. The Pisans sent a fleet of 120 sail to the first crusade, and their soldiers and sailors assisted at the taking of Nicæa, and afterwards at that of Antioch, as a reward for which they obtained a street of that city to establish a factory in. In 1099 the Pisans were at the taking of Jerusalem. In the following year they sailed into the sea of Marmara, and obliged the emperor Alexius to sign a treaty, by which he allowed them to establish a factory at Constantinople, with ample privileges. The Pisan fleet returned home in triumph, and their city was then entirely surrounded by walls.

In 1114, the Pisans sent a large armament, the largest that had ever sailed from their coast, to the conquest of the Balearic Islands, which were in possession of the Moors, and which had become a nest of Mohammedan pirates. The fleet consisted of 300 ships of various sizes, having on board 35,000 men and 900 horses. A great part of the troops consisted of mercenaries and also of contingents sent from the Pisan possessions in Sardinia. The archbishop of Pisa, Pietro Moriconi, himself commanded the expedition, of which we have an account in a curious Latin poem written by his own secretary, Laurentius Varnensis Diaconus, and published by Ughelli. Several of the descriptions in this poem bear so striking a resemblance to some in Tasso's 'Gerusalemme,' that suspicions have arisen that the Italian poet may have been acquainted with the MS. of the deacon. In April, 1117, the Pisans, in conjunction with Raymundo IV., count of Barcelona, accomplished the conquest of the Baleares, took the son of the Moorish king prisoner and brought him to Pisa, where he afterwards became a Christian. Unfortunately for the correct understanding of all those important transactions in the tenth, eleventh, and twelfth centuries, we have no history of Pisa properly speaking. Whilst Genoa, Venice, and Florence have had accomplished historians, Pisa has nothing but partial chronicles and detached memoirs, although numerous authentic documents must exist in the archives, from which a history of Pisa might be written. Pisa rose early to importance, but she also fell at an earlier period than her rivals, which may account for her history having been neglected.

In the year 1137, the Pisan fleet went to the coast of Naples to aid the pope and emperor against the Normans, and took the town of Amalfi, where it is reported that they found a copy of the Pandects, from which all other copies made in Italy were derived. This assertion however has been much controverted. (Fanucci, *Dissertazione Istorico-Critica sul Ritrovamento delle Pandette*, in his *Storia dei tre celebri Popoli Marittimi del' Italia*, Pisa, 1821.)

In the war between Frederic Barbarossa and the Lombard cities, Pisa sided with the emperor, and afterwards sent a fleet of fifty galleys to accompany him to the Levant on his crusade. In the following century the Pisans, as Guibelines, took the part of Frederic II. against the pope. In 1258, peace was made between Genoa and Pisa, through the mediation of Pope Alexander IV. In 1282 began the fourth war between Pisa and Genoa. Oberto Doria, the first naval officer of the age, commanded the Genoese. In the year 1284 he sailed out of Genoa direct for the port of Pisa with 58 galleys, and was joined off the rocky island of Meloria, which lies opposite Leghorn, by 30 more galleys, under Benedetto Zaccaria, which he ordered to conceal themselves behind the island. The Pisan fleet came out, having on board the flower of the fighting men of Pisa. The galley of Doria, supported by another Genoese galley, attacked and took the admiral ship of Pisa, which bore the great flag of the republic. At the same time the thirty galleys which lay concealed behind the island of Meloria appeared, and attacked the Pisans in flank and rear. The Pisans fought desperately till night, when a few only of their ships escaped into the harbour. They lost 3000 men killed or drowned, and 13,000 were carried prisoners to Genoa, where they were confined in chains, and where most of them died. Hence a proverb became current throughout Italy—'Those who want to see Pisa must go to Genoa.' The Genoese would have restored the prisoners, if Pisa had agreed to give up Sardinia to Genoa; but it is said that the prisoners themselves declared that they would not purchase freedom at such a price. The women of Pisa who went to Genoa to see their unfortunate husbands or brothers were told by the jailers that 'their countrymen were dying thirty or forty a-day, and their bodies were thrown into the sea, and that such would be the fate of all the Pisans.' In 1290, Conrad Doria attacked the Porto Pisano, destroyed its towers, and sunk ships filled with stones at the entrance. (Giov. Villani, *Cronaca*, b. vii., ch. 141.) From that time Pisa completely lost its rank as a maritime power, after a glorious career of four centuries, and Venice and Genoa were left alone to dispute for the naval supremacy in the Mediterranean.

In the meantime Pisa was distracted by domestic feuds. Florence, at the head of the Guelphs of Tuscany, assailed it by land, and in their distress the Pisans appointed as their captain-general, for ten years, Ugolino Count Gherardesca, a Guibeline feudal baron, but allied by marriage to the Guelphs. Ugolino acted as a tyrant. In order to keep himself in power, he favoured alternately Guelphs and Guibelines, while he proscribed the more independent leaders of both parties. He was opposed by the archbishop Ruggiero degli Ubaldini, a staunch Guibeline; and in 1288, being accused of betraying his country into the hands of the Guelphs of Florence and Lucca, an insurrection broke out against him, headed by the archbishop. Ugolino, being overpowered, was confined, with two of his sons and two of his grandsons, the latter mere boys, in a tower near the Arno, the key of which was entrusted to the archbishop, who after a short time threw it into the river, and left the wretched prisoners to die of hunger. This catastrophe has furnished Dante with the subject of one of his most powerful and appalling descriptions.

The Pisans then appointed Guido da Montefeltro their captain-general. He recovered by force the strongholds which Ugolino had put into the hands of the Guelphs of Florence and Lucca, and his troops, armed with crossbows, became the terror of Tuscany. Peace was made in 1293, and in 1299 Pisa made peace with Genoa also. Pisa continued attached to the Guibeline party, and at the death of the emperor Henry VII., in 1313, found herself exposed to the attack of all the Guelphs of Tuscany. The Pisans gave the chief command to Uguccione della Faggiuola, a captain of some renown, who took Lucca, in 1314, and afterwards defeated the Florentines in the battle of Montecatino. Uguccione however acted as a tyrant both to Lucca and Pisa, until an insurrection broke out simultaneously in both cities, in April, 1316. Pisa resumed its republican form of government, and in 1322 exiled fifteen of the Guibeline nobles, and made peace with the Guelphs. In the following year a general massacre of the Pisans took place in Sardinia, and the insurgents offered the island to Alfonso, the son of James II., king of Aragon. Pisa made a last effort to preserve Sardinia, but was obliged to give it up to the Aragonese, in 1326. In 1328 Castruccio Castracani, the great Guibeline leader, took Pisa by surprise, but his death soon after restored it to freedom. In 1341 the Pisans, who still retained much of their martial spirit, defeated the Florentines, and took possession of Lucca, and kept it till 1369, when the emperor Charles IV. obliged them to restore Lucca to its independence.

Pisa was now distracted by internal feuds between the democratic party, at the head of which was a merchant family of the name of Gambacorta, supported by Florence, and the Guibeline nobles and their adherents, whose party was called the Raspanti, and who were assisted by the Visconti lords of Milan. The Raspanti, having for a time the upper hand, exiled their antagonists, and began to annoy the Florentine merchants, who had settled at Pisa and in its port, as well at Livorno, which was already frequented as a port. Upon this the Florentines removed their counting-houses to Telamone, a port in the Maremma of Siena. Another revolution soon broke out at Pisa, and the party of the Gambacorta was restored; but Gian Galeazzo Visconti, duke of Milan, caused Pietro Gambacorta to be murdered by his own secretary Jacopo Appiano, who made himself master of Pisa, A.D. 1392. After the death of Jacopo, his son sold the city to Gian Galeazzo, in February, 1399, reserving to himself and his descendants the principality of Piombino. Pisa, as well as Genoa, Lucca, Siena, Perugia, and Bologna, was thus annexed to the dominions of the Visconti. At the death of Gian Galeazzo, in 1403, his natural son Gabriello Maria had Pisa for his share, but not feeling himself secure, he placed himself under the protection of Charles VI. of France, whose representative Marshal Boucicault had occupied Genoa, giving up to him Porto Pisano and Livorno. Boucicault thought of nothing but making the most of this piece of good luck. He sold Livorno to the Genoese for 26,000 golden ducats; and in 1405, he offered to sell Pisa to the Florentines for the sum of 400,000 florins, to be divided between him and Gabriello Maria. The Pisans however, being informed of this negotiation, rose against Gabriello Maria and his French auxiliaries, and obtained possession of the gates of their city, but they failed in their attack on the citadel. Boucicault then offered to give to the Florentines the citadel and the other strongholds which he had in the territory of Pisa for 206,000 florins, which the Florentines paid him, and were put in possession of the citadel, A.D. 1405. Gabriello Maria demanded his share of the purchase money, but Marshal Boucicault rid himself of his importunities by having him beheaded as a traitor to the French king.

The Florentines had the citadel of Pisa, but not the town, and the citizens soon retook the citadel also. They now asked peace of the Florentines, offering to repay them the money which they had paid to Boucicault, and in order to facilitate the negotiation, they recalled from exile Giovanni Gambacorta, whose family had always been favourable to the Florentine connection, and named him their captain-general. The Florentines however would hear of no proposal except the surrender of Pisa; but the citizens were not yet sunk so low as to yield to such a demand; they considered themselves the oldest republic of Tuscany, and they determined on resistance. The Florentines blockaded Pisa for about a year, and when the inhabitants were reduced to the greatest distress for want of provisions, Giovanni Gambacorta secretly treated with the Florentines, and agreed to open to them the gates for 50,000 florins and the country of Bagno, which he did on the night of the 8th November, 1406. Gino Capponi, the commissioner of Florence, behaved with great humanity; he maintained the strictest discipline among his troops, and he introduced into the town, together with his soldiers, a number of waggon-loads of bread which he distributed gratis to the famished inhabitants. But the pride of Pisa was too much hurt to be reconciled to the yoke. The principal families emigrated to Sardinia and Sicily, and most of the young men sought their fortune in the companies of mercenaries which were then scattered about Italy. Thus ended the career of Pisa as an independent state.

After eighty-eight years of Florentine dominion, when Charles VIII. of France came to Italy, in 1494, and showed himself hostile to Florence, the people of Pisa, headed by Simone Orlandi, rose in arms, drove away the Florentines, and restored their republican government under the protection of France. In 1499, after the French had left Italy, the Florentines besieged Pisa, but were repulsed, the women themselves assisting their townsmen in repairing the fortifications. In 1504 the Florentines resumed the siege, but they failed again. At last, in 1509, they formed a close blockade round the town, and Pisa was obliged to surrender through famine. A second emigration then took place, the wealthier families preferring exile to the loss of independence. Since that time Pisa has remained subject to Florence or to the rulers of Florence and of the rest of Tuscany.

The university of Pisa has been the chief means of maintaining some life in the town. It is divided into three faculties, theology, law, and medicine; it reckons among its professors several distinguished men, and is attended by about four hundred students. In 1839 Pisa was chosen for the place of a general assembly of men of science from all parts of Italy. Above 400 came, besides several foreigners. They were classed into six sections, each of which had its separate meetings. Memoirs were read, and prizes offered for the next annual assembly, which was appointed to take place at Turin in 1840.

PISA (Zoology). [MAIIDÆ, vol. xiv., p. 297.]

PISCES (the Fishes), the last constellation of the old zodiac. There is in the mythological stories (which are unworthy of note) a confusion between this constellation and Piscis Australis presently to be noticed. (See Grotius, in his notes on Aratus.) The constellation consists of two fishes linked by a string attached to their tails: they are not close together, the upper one being close to Andromeda, the lower one under the wing of Pegasus. The rectangular figure mentioned in PEGASUS will be a guide to the position of the two fishes: the line of α Andromedæ and γ Pegasi being parallel to the body of one fish, and that of γ Pegasi and α Pegasi to the body of the other.

The principal stars are as follows:—

* 107 Piscium is also 2 Arietis.

PISCI'COLA, one of the names for the *Hirudo Piscium* (*Hæmocharis*, Sav., *Icthyobdella*, Blainv.), which infests fish, especially the *Cyprinidæ*. [LEECHES, vol. xiii., p. 382.]

PISI'DIA (Πισιδία) formed the northern part of the Syrian and Roman provinces of Pamphylia. [PAMPHYLIA.] The name of Pamphylia was confined to a narrow slip of land along the sea-coast; while the mountainous country inland was called Pisidia. In these mountains, which formed a part of Mount Taurus, the Pisidians maintained their independence under the Persian empire. (Xen., *Anab.*, i. 9, § 14; ii. 5, § 13; iii. 2, § 23.) Neither the Syrian kings nor the Romans were able to subdue them, though the latter obtained possession of some of their towns, as for instance, of Antiocheia, where a Roman colony possessing the Jus Italicum was founded. (*Dig.*, 50, tit. 15, s. 8, § 10; Plin., *Hist. Nat.*, v. 24.) In the time of Strabo the Pisidians were governed by petty chiefs, and principally supported themselves by plundering their neighbours. (Strabo, xii., p. 570.)

We know very little of the physical geography of Pisidia, or of the situation of its towns. Mr. Fellows, who visited the western part of the country in 1838, informs us (*Excursion in Asia Minor*, p. 165) that the rocks are generally of marble, and some of common limestone with veins of marble running through them in all directions. Mr. Fellows states that 'the most singular features in this district are the mountains of volcanic dust, which he saw at 10 miles distant, looking as if they were smoking; this appearance being caused by the sand, which with every little wind is blown into clouds, and carried into the air and along the valleys. Out of these hills rise jagged points of marble rocks, each of which forms a nucleus of the drifting sand. The whole of this light sand or dust is tufa, the dust of the pumice-stone, and a volcanic production; the decomposed lime has in many parts mixed with this tufa and formed hills of Roman cement.'

The chief towns of Pisidia were Antiocheia, Sagalassus, and Selge.

Antiocheia, which, as already mentioned, was a Roman colony, was situated in the north-western part of the country. It was founded by a colony from the Magnesians on the Mæander. (Strabo, xii., p. 577.) It was visited by St. Paul and Barnabas, and it appears from the narrative in the *Acts of the Apostles* (xiii., 14-51) to have been a place of considerable importance. Its site is uncertain.

South-west of Antiocheia was Sagalassus, which is spoken of by Arrian (i. 28) as a considerable city. Strabo (p. 569. Casaub.) says it is also called Selgessus, and is a day's journey from Apameia: he adds that from the acropolis to the town is a descent of near 30 stadia. The ruins of Sagalassus, according to Mr. Fellows (p. 167), are very extensive, consisting of seven or eight temples, and three other long buildings, ornamented with cornices and columns, and with rows of pedestals on each side. Mr. Fellows also saw there a most beautiful and perfect theatre on the side of a higher hill than the rest of the ruins, and remarks that 'the whole town is a pile of superb public buildings, arranged in excellent taste both for seeing and being seen. The town has no trace of walls, but its tombs are to be seen carved in the rocks for miles around, with much architectural ornament.' These ruins are called by the Turks Boodroom, and were visited by Lucas (i., 180).

South-east of Sagalassus was Selge, the most important town in Pisidia. Selge is said to have been first founded by Calchas and afterwards by the Lacedæmonians, and in consequence of its good government soon became a large and flourishing town. Strabo says (xii., p. 570) that at one time it contained a population of 20,000 inhabitants. When Alexander marched through Pisidia, the inhabitants of Selge sent ambassadors to him, and obtained favourable terms from him. (Arrian, i. 28.) The territory of Selge, though mountainous, was, according to Strabo, very fertile. It produced abundance of oil and wine, and afforded pasturage for great numbers of cattle. The forests supplied a great number of timber-trees, of which the styrax was reckoned the most valuable. Mr. Fellows visited the ruins of a large city, situated about 10 miles north-east of the village of Boojak, which are in all probability those of Selge. Mr. Fellows describes these ruins as situated at the end of a ridge of mountains of white marble, which terminated abruptly in a deep and rich valley, and having only one side accessible, the other three rising perpendicularly perhaps 1000 feet. Mr. Fellows says (p. 172), 'that he rode for at least three miles through a part of the city, which was one pile of temples, theatres, and buildings, vying with each other in splendour.' He also states that he could scarcely guess the number of temples or columned buildings in the town, but that he certainly traced fifty or sixty; and in places where there were no remains above the surface he frequently saw vast arched vaults, similar to those forming the foundation of great public buildings.

PISI'DIA. [PORCELLANIANS.]

PISI'DIUM. [PISUM. (Zoology.)]

PISCIS AUSTRA'LIS or **AUSTRI'NUS**, or **NO'TIUS** (the Southern Fish), one of the old constellations situated directly under Aquarius: the stream from the water-pot of the latter constellation finishes at the mouth of this fish. It contains a remarkable star of the first magnitude, Fomalhaut, which only just rises above the horizon in these latitudes; when on the meridian, it is nearly in the same vertical circle with α and β Pegasi.

The principal stars are as follows:—

PISISTRA'TIDÆ. Hippias and Hipparchus were the two sons of Pisistratus, after whose death Hippias, the elder, succeeded to the rule. Thucydides tells us that the general opinion in his time was, that Hipparchus succeeded his father; this however he asserts to be a mistake, although in the same chapter (Thucyd., vi. 54) he observes incidentally that Hipparchus was not unpopular in his government, thereby implying that he had some share therein.*

Thucydides gives the brothers a character for encouraging manly virtue and cultivation (ἀρετὴν καὶ ξύνεσιν), for success in war, for piety, and for lenity in taxation. He says they only levied a rate of five per cent. on produce (τὰ γιγνόμενα), and that they rather interfered in the appointments to offices than with the administration of the laws themselves. He gives Pisistratus, son of Hippias, as one among others of the family (αὐτῶν) who served the office of archon.

Hipparchus, the younger son, lost his life by a conspiracy during the rule of his brother. He made offers of a degrading nature to Harmodius, a young Athenian, and meeting with a repulse, insulted his sister by refusing her admittance to a procession on the score of unworthiness. Harmodius resented the double indignity, and formed a plan with his friend Aristogeiton and some few others to relieve themselves from so hateful a tyranny. Hippias was their first object, but finding themselves detected, they attacked Hipparchus with the violence of insulted men, and slew him at the cost of their own lives. The other conspirators were detected. Hippias exchanged popular manners for suspicious cruelty, and at the same time took measures for ingratiating himself with Darius, king of Persia. In the fourth year of his rule he was expelled, with Spartan aid, by the fugitive Alcmæonids, and retired to Sigeum on the Hellespont, thence to Lampsacus, and lastly to the court of Persia, to return again in old age as the companion of the enemies of Greece, and to witness their overthrow at Marathon nineteen years afterwards. [MARATHON.] Herodotus relates that the Spartans repented of having expelled him, but that their plans to restore him were opposed by the Corinthians, and fell to the ground.

---

* In the famous song to Harmodius and Aristogeiton, the person killed is called τύραννος.

(Herodotus, v. 91-96; Thucydides, vi. 54-59.)

PISI'STRATUS (Πεισίστρατος), son of Hippocrates, lived at the same time with Crœsus, king of Lydia, and ruled over Athens in that fashion which was called by the name of tyranny.[*] He was the friend and relation of Solon, and, during the lawgiver's absence, had formed and led one of the three parties into which Athens was then split, namely, that of the Highlands: Megacles and Lycurgus heading those of the Coast and of the Plain. In the year 560 B.C., Pisistratus, having matured his plan of self-aggrandisement, drove into the market-place, himself and his mules marked with wounds inflicted by his own hand. He attributed these wounds to the enemies of the people, whose friend he was, and asked a guard, to which his brilliant services gave him some claim. Fifty mace-bearers were granted him, with whose help he made himself master of the Acropolis. His triumph however was in the first instance but short-lived.[†] Not long after, as Herodotus tells us, the other two factions joined to drive him out, his rule not being as yet deeply rooted. A new quarrel between Megacles and Lycurgus proved the means of his recal, and he strengthened himself by taking a daughter of Megacles for his second wife. As one of the Alcmæonids, she was held to be stricken with a curse, and Pisistratus, as his mother-in-law discovered, slighted her in consequence, so as to leave her a wife only in name. Pisistratus was again expelled, and continued in exile for about thirteen years; indeed he seems to have hesitated whether he should ever attempt to return. The judgment of his son Hippias however prevailed, and after many years' preparation, he landed at Marathon, took his foes by surprise, routed them, spared the fugitives, and was master of Athens. He strengthened himself by foreign and native mercenaries, by gaining the favour of the poor, and taking hostages of the rich, and ruled till his death, which took place B.C. 527.

Herodotus observes that Athens, great as she was under the tyrants, waxed yet greater afterwards: a way of expressing that the rule of Pisistratus was a breathing-time, after the reforms of Solon, which gave opportunity for those reforms to sink into the heart of the people, to become not merely enacted but active, and which rendered the next age more brilliant in production than it otherwise would have been. To Pisistratus also were owing the first steps in art taken at Athens, the first important public buildings, the first poor's-rate, under the guise of a tax on the rich to defray the expense of those public buildings, and lastly the first library, and the collection (as it is said) of the poems of Homer.

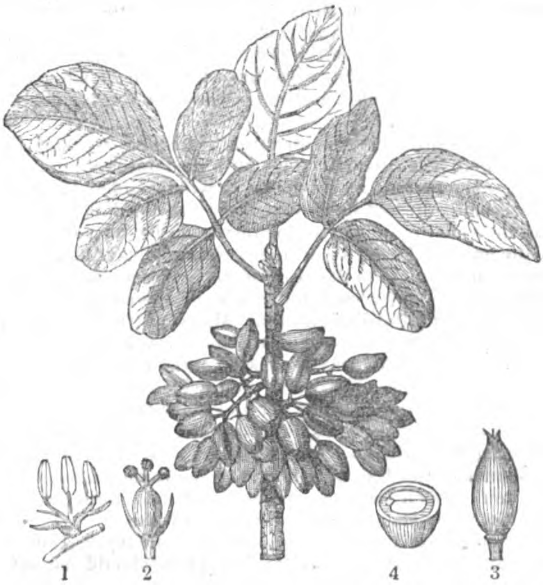
To Pisistratus too are owing, in one sense, the glories of the Persian war. Had he retired, as Hippias afterwards did, to the court of Persia, that war might have been antedated some sixty years, the power of Greece would have been two generations less mature, Persia so much less corrupt, and thus the issue of the contest might have been reversed.

(Herodotus, i. 59, 64; v. 65; vi. 35, 103.)

PISO, C. CALPU'RNIUS. [CÆSAR; CICERO.]

PISOLITE, or *Pea-Stone*, a variety of carbonate of lime, which occurs in globules from one-eighth to half an inch in diameter, imbedded in a calcareous cement; they usually consist of concentric lamellæ, in the midst of which is generally a grain of sand.

PISTA'CHIA NUT, the fruit of the *Pistacia vera* of botanists, is the produce of a small tree, or large bush, from 15 to 20 feet high; its leaves are alternate, unequally pinnated, without stipules, and consist of from 3 to 5 oval blunt leathery smooth leaflets. The flowers are small and arranged in short branched racemes from the old wood; some are male and others female; the latter are succeeded by dry drupes about the size of an olive, of a reddish colour, with a very thin rind, a brittle two-valved shell, and contain a single almond-like seed with a green embryo. The tree is originally from Asia Minor, but is now naturalised all over the South of Europe, where the fruit is in request for confectionary and for the dessert.



Pistacia vera.

1, a male flower; 2, a female; 3, a ripe fruit; 4, a seed cut transversely.

PISTO'IA, a town of Tuscany, in the compartimento or province of Florence, is situated twenty miles north-west of the capital, in a plain at the foot of the Apennines, near the river Stella, a tributary of the Ombrone, which is an affluent of the Arno. Pistoia lies on the high road leading from Florence to Modena over the Apennines. It is a well-built town, of considerable size, but rather thinly inhabited; it contains about 10,000 inhabitants, and is a bishop's see.

Pistorium, or Pistoria, does not appear to have been a place of importance under the Romans, except that it was near one of the passes leading into Cisalpine Gaul, and was probably a military station. In the 'Antonine Itinerary' the station is marked 'ad Pistores.' Sallust (*Catilin.*, 57) mentions that Catilina assembled his followers in the territory of Pistoria, with the intention of leading them across the mountains into Gaul, but he was forestalled by Q. Metellus Celer, who encamped on the other side of the mountains.

Pistoia was a place of importance under the Longobards, whose king Desiderius enclosed it with walls. It was afterwards an independent municipality, until it was subjugated by Florence, about A.D. 1150. It appears however that the Florentines allowed it to retain its municipal franchises, but reserved to themselves the appointment of the podesta or chief magistrate. There was an influential family of Pistoia of the name of Cancellieri. This family in course of time became divided into several branches, and a dispute arising among them which was attended with bloodshed, the various members of the family were ranged into two opposite factions, one of which called itself 'I Bianchi,' or 'the white,' because descended from the wife of one of the former Cancellieri whose name was Bianca. The opposite faction took the name of 'Neri,' or 'the black.' These factions having each numerous adherents and dependents, the whole town of Pistoia became divided between the Bianchi and the Neri. The people of Pistoia are represented by the contemporary chroniclers as a strong and daring, but fierce and quarrelsome race. Some of the Cancellieri of the Bianchi faction being connected with a Florentine party-leader, named Veri De Cerchi, an influential man among the Florentine Guelphs, the latter contrived to appoint as chief magistrate of Pistoia a friend of his own, called Cantino. This person favoured the Bianchi, and in the next election of the elders or municipal councillors he had them all chosen from among the Bianchi, saying that such was the will of the council of Florence, which however was not true. This measure excited many disturbances, which the elders of Pistoia, supported by the Florentines, availed themselves of in order to oppress their rivals of the Neri faction, on whom they imposed fines and other penalties. This state of things continued for several years, during which the Florentine podestas who were successively sent to Pistoia contrived to fill their pockets from fines and condemnations. (Dino Compagni, *Cronaca.*) These things happened in the latter part of the thirteenth century. But the quarrel between the Neri and the Bianchi spread to Florence, where the two families of Cerchi and Donati disputed for the pre-eminence in the councils of the republic. The Donati assumed the name of Neri, and, with the assistance of Charles of Valois, they succeeded in driving away their antagonists in 1301. [Dante.]

---

[*] The classical reader need not be reminded that the Greek word from which our word *tyrant* is taken, only means one who rules contrary either to the letter or spirit, or both, of the laws, not necessarily one who acts either with cruelty or even injustice. Thus Herodotus (i. 59) expressly tells us that Pisistratus 'ruled without either disturbing authorities or changing institutions, and that he governed the state on the principles then established, and ordered it fairly and well;' yet Pisistratus was a tyrant.

[†] Mr. Clinton says the time is uncertain; Mr. Thirlwall gives it at five years.

The Florentine Neri afterwards proceeded to attack Pistoia, where the Bianchi were still predominant; but not being able to take it by force, they blockaded the town, which being pressed by famine, the council ordered the poor and most of the women and children to be turned outside of the gates. These unfortunate creatures, says Dino Compagni, on coming into the camp of the besiegers, were shamefully used by their own townsmen of the adverse faction, who were with the Florentines. Many of them, after enduring all sorts of abuse, had their noses, or hands, or feet cut off, and in this mutilated state were carried back to the foot of the town-walls, in order to frighten the besieged, but the magistrates did not allow them to be taken in, and thus they died miserably outside. (Dino Compagni, *Cronaca Fiorentina.*) Those who are so ready to extol the prosperity of the Italian republics of the middle ages, ought to dwell on such scenes as these, in order to form a correct opinion of the state of society in those times.

At last Pistoia surrendered, on the 10th April, 1306, on the condition that persons and property should be safe; but no sooner had the Florentines entered the town, than they razed the walls to the ground. Pistoia never recovered from that blow. It continued, with some short interruptions, to be subject to Florence, and followed its destiny through the various changes of government.

There are many remarkable buildings in Pistoia. The cathedral, which was built by the Countess Matilda, in the early part of the twelfth century, and restored by Nicolo di Pisa, contains some good paintings, basso-relievos, and the monument of Cino da Pistoia, the friend of Dante and Boccaccio, a jurist and an elegant poet; and also that of Cardinal Nicola Forteguerri, a distinguished character of the fifteenth century. The other churches worthy of notice are, S. Pietro Maggiore, L'Annunziata, S. Filippo Neri, Santa Maria dell' Umilta, S. Gio. Battista, S. Domenico, and S. Giovanni Rotondo. The palace del Comune, or degli Anziani, dates from the thirteenth century, and contains several monuments of the middle ages. The episcopal palace, raised in the last century by the Bishop Ricci, is a sumptuous building. The clerical seminary was also built by Ricci. La Sapienza, or the public schools, has a good library. There is also at Pistoia an academy of sciences and belles-lettres. The private palaces of the families Bracciolini, Cancellieri, Rospigliosi, Tolomei, and Forteguerri contain good paintings. (Valéry, *Voyages Littéraires en Italie.*)

Pistoia has produced distinguished men in almost every branch of learning and art: Cino da Pistoia, the poets Forteguerri and Bracciolini, Pope Clement IX., the poetess Corilla; the architects Ventura and Vitoni; the painters Gerini, Malatesta, and Cipriani (who died in London, in 1790); the sculptors Ennio da Pistoia, Ognabene, and Cornacchini; and many more, who are noticed by Tolomei, in his 'Guida di Pistoia,' 8vo., 1821; by Zaccaria, 'Bibliotheca Pistoriensis descripta,' Turin, 1754; and by Ciampi, 'Notizie Inedite della Sagrestia Pistoiese dei belli Arredi,' Pisa, 1812. Ciampi has also published an interesting biography of Cino, 'Vita e Poesie di Messer Cino da Pistoia,' 8vo. Pisa, 1813.

The history of Pistoia has been written by Fioravanti, 'Memorie Storiche,' Lucca, 1758, and also in the 'Istorie Pistolesi,' an anonymous work, printed at Florence, by Giunti, 1578. Viani has written 'Della Zecca e della Monete di Pistoia,' Pisa, 1813.

PISTOL. [Arms.]

PISUM. [Pea.]

PISUM (Zoology), Megerle's name for a genus of conchifers (*Pisidium*, Leach), separated from Cyclas. *Quæretamen.*

PITCAIRN'S ISLAND is a small island in the Pacific, the centre of which is in 25° 3′ 37″ S. lat. and 130° 8′ 23″ W. long. It is about seven miles in circumference, and very high, with precipitous sides, and without anchorage. Some of the rocks are volcanic. The highest point of the island is 1109 feet above the sea-level. The ascent from the beach is generally extremely steep, and two of the three landing-places are not used. The third landing-place is on the north side of the island, but the approach is very dangerous. The soil which covers the rock consists of clay mixed with sand; it is very rich and of great depth. It is supposed that the island could maintain a population of 1000. There is only one well of good and one of indifferent water. Most of the mountains are still covered with trees. This island, which was discovered by Cook in 1777, now contains a colony of Englishmen and Otaheitean women, whose offspring form the whole population of the island. After the mutiny of the Bounty [Bligh], Fletcher Christian sailed first to Toobouai, one of the Pamuto Islands, and then to Otaheite, where he took in animals and plants, and then returned to Toobouai, with the intention of settling there, having left the larger part of his crew in Otaheite and taken with him six males and twelve women. But not finding the natives of Toobouai inclined to permit them to settle on their island, he established his colony on Pitcairn's Island in 1790. This island was first visited by an American vessel in 1809, and afterwards by the Briton, in 1814. In 1826 the island was surveyed by Captain Beechey. As a report prevailed that the inhabitants suffered much from want of water, a vessel was sent to remove those who were willing to go to Otaheite, which was effected in 1831, when the population had increased to 87 in number. But the new settlers found that they had not improved their condition by this change, and they returned to Pitcairn's Island in 1832. They are a fine and robust people, high-spirited, and intelligent, and speak both the Taheitian and English languages fluently. Their food is chiefly vegetable. Yams, which are abundant and of excellent quality, are the principal article of food. Cocoa-nuts, bananas, and pumpkins also grow, but the bread-fruit tree yields a scanty crop of indifferent fruit. Swine, goats, and domestic fowls are reared, and fish is rather abundant. Before their removal to Otaheite, the islanders were distinguished by their patriarchal simplicity, modified by the English character; but since that time they have taken to drinking spirits, the preparation of which they had learnt in Otaheite.

(Shillibeer's *Narrative of the Briton's Voyage:* Beechey's *Narrative of a Voyage to the Pacific, &c.; Recent Accounts of the Pitcairn Islanders*, by Barrow, in *London Geogr. Journal*, vol. iii.; Bennet's *Extracts from the Journal of a Voyage round the Globe*, in *London Geogr. Journal*, vol. vii.)

PITCAIRNE, ARCHIBALD, M.D., was born at Edinburgh in 1652. He studied divinity and afterwards law at that university with extreme ardour; but being obliged by the failure of his health to go to Montpellier, he there acquired a love of medicine. On his return to Edinburgh, he devoted himself to the pursuit of its several branches and to the study of mathematics, by the application of which he believed (as many of his contemporaries did), that much light might be thrown upon the phenomena of life. He afterwards studied in Paris, and thence returning to his native place, he soon became the most renowned practitioner in it. In 1692 he was invited to the professorship of medicine at Leyden; but his mathematical theories being less agreeable than the doctrines of vitalism, which were then becoming prevalent, he held the appointment little more than a year, and then returned home, having reaped no other honour than that of having had the celebrated Boerhaave among his pupils. He died at Edinburgh, in 1713.

Dr. Pitcairne's chief work was published after his death, under the title of 'Elementa Medicinæ Physico-Mathematica;' but, like most others of the same class, it contains little that is now considered valuable. He also wrote a work to prove Harvey's claim to the discovery of the circulation of the blood, and several dissertations on the utility of mathematics in the study of medicine.

PITCH. [Tar.]

PITCH, in Music, a tone or degree in musical sounds, whether grave, or acute, or intermediate. It may be the key-note, or the note on which any air or part begins. The pitch of c, the third space in the treble, is a sound produced by 512 vibrations in one second. [Concert-Pitch.]

PITCHSTONE occurs massive. Structure compact, sometimes slaty, occasionally curved. Fracture imperfectly conchoidal. Hardness 5·0 to 6·0. Colour brown, black, grey, red, &c., and variously mixed. It is generally dull, but has sometimes a resino-vitreous lustre. Translucent. Opaque. Specific gravity 2·3 to 2·7.

It occurs at Meissen in Saxony, at Newry in Ireland, and in the Island of Arran, and other places.

Analysis of Irish pitchstone by Knox:—Silica, 72·80; alumina, 11·50; soda, 2·85; lime, 1·20; protoxide of iron, 3·03; water, 8·50.

PITCHSTONE (Geology), a siliceous rock of igneous origin, generally occurring in dykes which traverse the strata, or in overlying columnar masses. Among recent volcanic rocks its analogue is obsidian. M'Culloch gives the characters of pitchstone in the following leading divisions:—

1, Simple: *a*, amorphous, massive; *b*, concretionary.
2, Porphyritic: pitchstone-porphyry of mineralogists.
3, Concretionary spheroidal; pearlstone of mineralogists.
4, Amygdaloidal: containing imbedded zeolites, &c.

The colours are extremely various; the texture varies from almost glassy to granular, and thus allows of passage into hornstone.

PITEA. [Bothnia.]

PITH is a cellular substance found in the centre of the branches, but not roots, of Exogens. When young it is filled with fluid and with grains of starch, which gradually disappear as the foliage in communication with the pith becomes organised; and there can be no doubt that this part is in reality a magazine of nutriment upon which the leaves may feed in their infant state. After the leaves in communication with it are organised, it dries up and dies. The old statements that it is the seat of fertility, a tree becoming unfruitful whose pith is destroyed, like the more modern assertion that it is the seat of nervous irritability, are mere fables. It communicates with the bark by means of the medullary rays, and with the leaves by means of cords of fibro-vascular tissue emanating from the medullary sheath. In Endogens there is no pith, but the office of that part is probably performed by the cellular substance in which the fibro-vascular cords of woody matter are imbedded.

PITHE'CIA. [Sakis.]

PITHE'CUS, M. Geoffroy's name for the Orangs. [Ape; Chimpanzee; Orang-Utan.]

PITHIVIERS. [Loiret.]

PITHYS. [Merulidæ, vol. xv., p. 122.]

PITISCUS, SAMUEL, was born at Zutphen, March 30, 1637, and in his younger days was the scholar of John Frederick Gronovius. He was appointed master of the public school at Zutphen in 1685, and about the same time was entrusted with the direction of the college of St. Jerome at Utrecht. This last employment he retained till 1717, when, being in his eightieth year, he resigned it. His most important works were his 'Lexicon Latino Belgicum,' the best edition of which is that published at Dort in 1725, and his 'Lexicon Antiquitatum Romanorum,' 2 tom. fol., Leov., 1713. His editions of Quintus Curtius, Solinus, Suetonius, and Aurelius Victor are well known to classical scholars. He likewise edited Pomey's 'Pantheon Mythicum' and Rosin's 'Antiquitatum Romanorum Corpus,' 4to., Utrecht, 1701. He prepared large collections for a 'Lexicon Catullo-Tibullo-Propertianum.' He died February 1, 1727. He acquired considerable property by his works, and is said to have left at his death ten thousand florins to the poor.

(Casp. Burmanni *Trajectum Eruditum*, 4to., Traj. ad Rh., 1738, pp. 268-272; Chalmers's *Biog. Dictionary*, vol. xxiv., pp. 530, 531.)

PITONNELLUS, De Montfort's name for a genus of turbinated testaceous gastropods, *Rotella* of authors. [Turbinidæ.]

PITS, or PITSEUS, JOHN an English biographer, born at Alton in Hampshire, A.D. 1560. He received his early education at Winchester school, whence, at the age of eighteen, he was elected a probationer fellow of New College Oxford, but in less than two years he left the kingdom as a voluntary Romish exile, and went to Douay. He went thence to Rheims, and a year afterwards to the English college at Rome, where he studied seven years, and then returned to hold the professorship of rhetoric and Greek at Rheims. Toward the end of 1590, he was appointed governor to a young nobleman, with whom he travelled into Lorraine, and afterwards went through Upper Germany and Italy. He subsequently returned to Lorraine, where he was preferred to a canonry of Verdun. When he had passed two years at his new residence, Antonia, daughter to the duke of Lorraine, who had married the duke of Cleves, invited him to Cleves to be her confessor. He continued in her service twelve years, till her death, when he returned a third time to Lorraine, and was promoted to the deanery of Liverdun, where he died in 1616. The leisure he enjoyed while confessor to the duchess of Cleves enabled him to compile a work which alone has made him known to posterity, 'The Lives of the Kings, Bishops, Apostolical Men, and Writers of England.' They were comprised in four large volumes; the first containing the lives of the kings, the second of the bishops, the third of the apostolical men, and the fourth of the writers. The three first are preserved in the archives of the collegiate church of Verdun; the fourth only was published after his decease, in 4to., at Paris, 1619 and 1623, under the title of 'Joannis Pitsei Angli, S. Theologiæ Doctoris, Liverduni in Lotharingia Decani, Relationum Historicarum de Rebus Anglicis Tomus Primus,' &c.; but the running title by which it is most frequently quoted is 'De Illustribus Angliæ Scriptoribus.' In this work Pits took much from Bale's book 'De Scriptoribus Majoris Britanniæ' without acknowledgment, pretending at the same time to abhor both Bale and his work. He also quotes Leland's 'Collectanea de Scriptoribus Angliæ,' which Wood asserts he never could have had the means of perusing, but must likewise have taken at second hand from Bale. His partiality is also great. He leaves Wickliffe and his followers, together with the Scotch and Irish writers, entirely out of his work, and in their room gives an account of the Roman Catholic writers, such especially as had left the kingdom after the Reformation in Queen Elizabeth's time, and settled at Rome, Douay, Louvain, &c. This however is the best and most valuable part of Pits's work. He published three small treatises, which are less known: 'De Legibus,' Triers, 1592; 'De Beatitudine,' Ingolst., 1595; 'De Peregrinatione,' 12mo., Düsseldorf, 1604. The last is dedicated to the Duchess of Cleves. (Wood, *Athen. Oxon.*, ed. Bliss, vol. ii., col. 172, 177; *Biograph. Brit.*; Chalmers's *Biogr. Dict.*, vol. xxiv., p. 532-534.)

PITT, WILLIAM, EARL OF CHATHAM, was the second son of Robert Pitt, Esq., of Boconnoc, near Lostwithiel, in Cornwall, by Harriet Villiers, sister of the Earl of Grandison (an Irish peer), and the grandson of Thomas Pitt, governor of Madras, the possessor of the celebrated Pitt diamond, which, according to an account published by himself, he bought in India for 24,000*l.*, and sold to the French king for 135,000*l.* William Pitt was born at Boconnoc, on the 15th of November, 1708. He was educated at Eton, whence he went in 1726 as a gentleman commoner to Trinity College, Oxford. On leaving the university, he obtained a cornetcy in the Blues, and entered parliament in January, 1735, as one of the representatives for the borough of Old Sarum, which was the property of his family.

He immediately joined the Opposition, of which the head at this time was Frederic, Prince of Wales, but for the first session he took no part in the proceedings of the House beyond giving his vote. His maiden speech was delivered on the 29th of April, 1736, on occasion of a motion made by Mr. Pulteney, for an address of congratulation to his majesty on the recent marriage of the prince. The motion was seconded by Mr. Pitt, and was supported by his friend George Lyttelton (afterwards the first Lord Lyttelton), who held the office of secretary to his royal highness. Pitt's speech is described by Tindal as 'unmixed with any strains but that of declamation;' 'and,' he adds, 'we have few models of antiquity more perfect in that kind, it being more ornamented than the declamations of Demosthenes, and less diffused than those of Cicero.' Pitt's appearance and elocution must have been imposing from the first; for there was certainly nothing in the matter of this speech, if we may judge from what appears to be a verbatim report of it, to put any one in mind of either Demosthenes or Cicero. The animosity between the prince and his father now rose to a great height, and, among the other adherents of the former, Pitt experienced the vengeance of the court by being deprived of his commission. It appears indeed that his dismissal from the army took place within a few days after the delivery of his speech. (See the date published for the first time from the Records of the War-Office in an article in the 'Quarterly Review,' No. 131, for June, 1840.) For this loss however he was recompensed by being appointed by the prince one of the grooms of his bed-chamber. The next occasion on which he is recorded to have taken any part in the debates of the House was on an opposition motion for a reduction of the army, on the 3rd of February, 1738; nor did he become a frequent speaker till some years later. He made another speech, of more energy and vehemence than he had yet displayed, in the debate on the 8th of March, 1739, on the convention with Spain; but his name does not again occur in the reports of the debates, either in that or in the following session. He appears to have first taken a prominent part as a debater in the discussion of the successive motions directed against Walpole, in January and February, 1741, towards the close of the seventh and last session of this the first parliament in which he had a seat. It was in one of these debates, professedly on the second reading of the ministerial bill for the encouragement and increase of seamen, which took place on the 27th of January, that he is made, in the report drawn up by Johnson for the 'Gentleman's Magazine,' to have delivered his celebrated philippic in reply to the elder Horatio Walpole (the minister's brother, and afterwards Lord Walpole of Woolterton), beginning 'The atrocious crime of being a young man, which the honourable gentleman has with such spirit and decency charged upon me, I shall neither attempt to palliate nor deny, but content myself with wishing that I may be one of those whose follies may cease with their youth, and not of that number who are ignorant in spite of experience.' It is believed however that this brilliant declamation is almost entirely Johnson's own; the style at any rate is certainly his, and not Pitt's.

To the next parliament, which met in December, 1741, Pitt was again returned for Old Sarum. Walpole resigned in the beginning of February, 1742; but his retirement did not leave the road to office open to Pitt, against whom the king had conceived a violent prejudice, not only on account of the prominent and effective part he had taken in the general assault upon the late administration, but more especially in consequence of certain strong opinions he had expressed on the subject of Hanover, and the public mischiefs arising from his majesty's partiality to the interests of that electorate. It is understood also that Pulteney, the framer of the new ministry, owing to a dislike which existed between his friend Lord Carteret (afterwards earl of Granville), who now became one of the secretaries of state, and Lord Cobham, the friend and relation of Pitt, Lyttelton, and George Grenville, found it impossible or unadvisable to bring any one of the three last-mentioned persons into office for the present, although the most distinguished members of his party. Grenville's elder brother Richard (afterwards Earl Temple) and Lyttelton's father had married sisters of Lord Cobham, and Pitt's elder brother was married to a sister of Lyttelton's.

The nominal head of the new ministry was Lord Wilmington, who held the office of first lord of the treasury; but when Walpole, in a few months after his own fall, had contrived to extinguish Pulteney by forcing him into the House of Lords, where, from being the most popular and powerful man in England, he suddenly dropped down into a despised nonentity as earl of Bath, the real supremacy in the cabinet was divided, or rather contended for, between Carteret and the two Pelhams, the elder of whom, the duke of Newcastle, was the other secretary of state, his brother Henry Pelham being paymaster-general. Wilmington died in July, 1743, and although by Walpole's advice Mr. Pelham was then appointed first lord of the treasury and chancellor of the exchequer, Carteret notwithstanding derived from the favour of the king a power really superior to that of his rival, and upon which his bold and impetuous character made him presume in a manner equally offensive to the public and to his colleagues. In this state of affairs, Pitt soon threw himself again into opposition, and became more active and acrimonious in his denunciations of the new ministry than he had ever been in inveighing against Walpole himself. On the subject of the king's Hanoverian partialities in particular, to his sympathy with which Carteret was understood chiefly to owe his influence over the royal mind, the eloquent commoner was now louder and more eloquent than ever. He and Lyttelton are also said to have both been members of the secret committee of six, headed by Bubb Dodington (afterwards Lord Melcombe), by which all the operations of the opposition were now directed.

Carteret, now become lord Granville, was dismissed a few days before the opening of the session of parliament in November, 1744; and what was called the *broad-bottom ministry* was formed, with Mr. Pelham, in reality as well as in appearance, at its head. But although his friends George Grenville and Lyttelton both obtained places in the new arrangement, Pitt's time was not yet come; his recent conduct in fact had given additional provocation to the king. From this date however he ranged himself among the supporters of administration, and not merely softened his tone touching Hanover and other delicate points, but even did not scruple to unsay and retract a good deal of what had in past years formed the staple of his oratory.

In the beginning of the year 1746 an attempt was made by the duke of Newcastle to overcome the king's repugnance to the admission of Pitt into office; but the insinuations of Pulteney are said to have been employed to strengthen the royal aversion; and his majesty made a desperate struggle to escape the threatened infliction. On the 10th of February lord Bath was actually named first lord of the treasury and the head of a new administration, with his friend Granville for secretary of state; but it was found that this project could not be carried through; and four days afterwards Pelham and all his colleagues were again in the occupation of their several offices. On the 22nd Pitt was appointed one of the joint vice-treasurers for Ireland; and on the 6th of May following he was promoted to the more lucrative office of paymaster-general. After each of these appointments he was re-elected for Old Sarum. To the next parliament however, which met in November, 1747, he was returned, by the influence of the government, for Seaford, one of the Cinque Ports. On this occasion the duke of Newcastle is said to have personally interfered in the election in the most open manner; but when the return was petitioned against on this account, Mr. Pitt, according to the report of the debate, 'treated the petition with great contempt, and turned it into a mere jest;' and the motion for its being taken into consideration was negatived by a great majority. The opposition in fact was now reduced to a helplessly inconsiderable fraction of the house.

A few years before, Pitt's pecuniary circumstances had been rendered much easier by a legacy of 10,000*l.*, left to him by the duchess of Marlborough, 'in reward,' as her will expressed it, 'for the noble disinterestedness with which he had maintained the authority of the laws, and prevented the ruin of his country.' He had thereupon resigned his post in the household of the Prince of Wales, and indeed had separated himself entirely from his royal highness, who still remained the recognised head of the opposition, such as it was, till his death in March, 1751. Mr. Pitt distinguished himself in his new place by a proud disdain of certain sources of emolument of which his predecessors had been accustomed to avail themselves; and also by the frank and courageous style in which he went on urging and defending the course of national policy, especially in relation to foreign affairs, which the whole of his previous parliamentary life had been spent in opposing and reprobating. His change of opinion or feeling may be illustrated by a speech he made in the debate on the address of thanks at the opening of the session in January, 1751, in reference to the abandonment by the government, at the recent peace of Aix-la-Chapelle, of the claim of exemption from search for British ships when found near the coast of Spanish America—a claim which, when in opposition, he had passionately insisted ought to be made an indispensable preliminary to any treaty of peace with Spain. 'I was then,' he said, 'very young and sanguine; I am now ten years older, and have had time to consider things more coolly.' And he added, referring to a motion which he had formerly supported for an address to the crown against concurring in any peace in which this claim should not be recognised, 'I am also convinced that all addresses from this house, during the course of a war, for prescribing terms of peace, are in themselves ridiculous;....and as the crown has the sole power of making peace or war, every such address must certainly be an encroachment upon the king's prerogative, which has always hitherto proved to be unlucky.' However wise this language may have been, or however sincere and honest, there is no bitterness of deprecation and scorn which it would not have drawn down from Pitt upon the head of any luckless member of the government by whom it might have been uttered but a very few years before.

The discussions upon the Regency Bill, which in this session followed the death of the Prince of Wales, first brought out that opposition between Pitt and Henry Fox (afterwards the first Lord Holland), which not only made them rivals during their lives, but gave rise to a competition for the chief power in the state in which their two celebrated sons also spent their days. For the present the influence of the Pelham section of the cabinet, which Pitt represented, prevailed over that of the Bedford section, which supported Fox: Fox himself, who was secretary at war, kept his place, as well as Pitt; but his patron the duke of Bedford resigned, along with one or two friends who also belonged to the cabinet, and whose seats were immediately filled by connections or dependants of the Pelhams. The arrangements now made subsisted till the sudden death of Mr. Pelham, in March, 1754; upon which the duke of Newcastle was appointed first lord of the treasury and premier. A few weeks after, the parliament was dissolved. This year Pitt drew closer his connection with the Grenvilles by his marriage with Hester, sister of the right honourable George Grenville, and of his brother, the then viscount Cobham, afterwards earl Temple.

To the new parliament, which met in November, 1754, Pitt was returned for the duke of Newcastle's borough of Aldborough in Yorkshire. Before the end of the session however a complete breach had taken place between Pitt and his grace; which ended, after about a year, in a reconstruction of the government. On the 15th of November, 1755, Fox was appointed secretary of state, and, five days after, Pitt and his friend Grenville both received intimations that his majesty had no further occasion for their services. But after about another year, Newcastle, already deserted by Fox, found it necessary to resign a position for which the nearly unanimous voice of the public had pronounced him unfit, and his occupation of which had only been signalised by a series of national disasters and disgraces. In this crisis of affairs the king, after a short struggle, found it necessary to call in the popular favourite of the hour; and although the office of first lord of the treasury was given for the present to the duke of Devonshire, Pitt, appointed secretary of state, became the actual premier, with a cabinet consisting of his personal friends and the other chief members of his party, in December, 1756. He was now returned both for the town of Buckingham and for Oakhampton, and chose to sit for the latter. But this first ministry of Pitt's lasted only for a few months. The king's old aversion had not been weakened by the manner in which the man of the people had been forced upon his acceptance; and in April of the year following (1757), his majesty abruptly sent Lord Temple his dismissal from the post he held of first lord of the admiralty, an act which was immediately followed, as must have been foreseen and designed, by Mr. Pitt's resignation. For two months and a half the country remained without a government, during which time the court applied in succession to almost every section of party-men in the country, without being able to prevail upon any individual to undertake the management of affairs. At last, on the 11th of June, Lord Mansfield received full powers from his majesty to open negociations with Mr. Pitt and the duke of Newcastle; the result of which was that before the end of the month Pitt was again premier, with the seals of secretary of state. Newcastle was re-appointed first lord of the treasury; Pitt's friends, earl Temple, George Grenville, and Mr. Legge, became respectively lord privy seal, treasurer of the navy, and chancellor of the exchequer; Mr. Fox was made paymaster of the forces; and even Lord Granville obtained a seat in this comprehensive cabinet as president of the council. Upon this new appointment Mr. Pitt was chosen member for Bath, for which he was also returned to the next parliament, which met in November, 1761, and which was the last place he represented.

The detail of the brilliant military successes which distinguished Mr. Pitt's administration belongs to the general history of the country; but an enumeration of the principal results of his conduct of the war may be found in the article on George II., vol. xi., p. 161. The new reign however brought along with it the ascendancy in the cabinet of Lord Bute and his friends [Bute, Earl of, and George III.]; and on the 5th of October, 1761, a few weeks before the meeting of parliament, Mr. Pitt, on the refusal of his colleagues to acquiesce in his proposition of declaring war against Spain, resigned, along with his friend Earl Temple, the only member of the cabinet who had supported his views. On his retirement however a pension of 3000*l.* a year for the lives of himself, his wife, and his eldest son, was conferred on Pitt, and his wife was made a peeress with the title of Baroness Chatham. These honours and rewards did not increase the popularity of the late premier.

In his new position nevertheless Pitt acted a sufficiently independent part. Without engaging in any factious opposition, but on the contrary giving a general support to the government, he directed his eloquence against certain of their measures with all his old energy and fervour. In particular he denounced the preliminaries of peace signed in November, 1762; resisted as far as he could, though ineffectually, the famous bill for extending the excise regulations to the manufacture and sale of cider, brought forward in the same session; and the next session took a conspicuous part in maintaining against ministers the illegality of general warrants on the proceedings that arose out of the affair of Wilkes and his 'North Briton.' Before this last question arose, the premiership, by the sudden resignation of Lord Bute, in April, 1763, had fallen for a time into the hands of George Grenville, who had continued in office when his brother Lord Temple and Pitt had retired in October, 1761, and had ever since remained separated from his old friends. In September, 1763, an attempt had been made to bring Pitt again into the cabinet; but he declined the overtures made to him when he found he was not to have the first place; and when parliament met in November the head of the ministry was considered to be the Duke of Bedford, who, on the failure of the negotiation with Pitt, had been appointed to the office of president of the council

Another attempt which the king made, in May, 1765, to obtain the assistance of Mr. Pitt in forming a new cabinet, proved equally unsuccessful with the last, and so did a renewal of it in June following. It was while these negotiations were in progress that Burke, not yet himself introduced to public life, but a keen observer of the scene in which he was soon to be one of the most brilliant figures, wrote to Flood: 'Nothing but an intractable temper in your friend Pitt can prevent a most admirable and lasting system from being put together, but this crisis will show whether pride or patriotism be predominant in his character; for you may be assured he has it now in his power to come into the service of his country, upon any plan of politics he may choose to dictate, with great and honourable terms to himself and every friend he has in the world, and with such a strength of power as will be equal to anything but absolute despotism over king and kingdom. A few days will show whether he will take this part, or continue on his back at Hayes talking fustian.'

The result was the accession of the Rockingham administration, in which Pitt had no place, but whose measures generally had his support, although in the debate on the address in January, 1766, he declared that he could not give them his confidence, adding, while he bowed to the treasury bench, 'Pardon me, gentlemen, confidence is a plant of slow growth in an aged bosom; youth is the season of credulity.' It was upon this occasion that he announced his peculiar view of the constitutional question involved in the dispute already begun with America. 'It is my opinion,' he said, 'that this kingdom has no right to levy a tax upon the colonies. At the same time I assert the authority of this kingdom over the colonies to be sovereign and supreme in every circumstance of government and legislation whatsoever. Taxation is no part of the governing or legislative power. The taxes are a voluntary gift and grant of the Commons alone. In legislation the three estates of the realm are alike concerned; but the concurrence of the peers and the crown to a tax is only necessary to close with the form of a law. The gift and grant is of the Commons alone. To this singular and not very intelligible theory Pitt clung to the end of his days, dying, indeed, it may be said, in the utterance and vindication of it.

Meanwhile in the difficulties to which this ministry also soon found itself reduced, another application was made to Pitt, so early as the end of February, 1766. At that time it came to nothing, but the attempt was renewed after a few months; and in the end Pitt received a *carte blanche* to frame a new cabinet, which was completed about the beginning of August. And a very extraordinary piece of handywork it turned out. 'He made an administration,' as Burke has said in a famous passage, 'so chequered and speckled; he put together a piece of joinery so crossly indented and whimsically dovetailed; a cabinet so variously inlaid; such a piece of diversified mosaic; such a tessellated pavement without cement; here a bit of black stone, and there a bit of white; patriots and courtiers, king's friends and republicans, whigs and tories, treacherous friends and open enemies, that it was indeed a very curious show, but utterly unsafe to touch and unsure to stand on.' What most astonished the public in the whole arrangement was the manner in which Pitt disposed of himself: he appropriated the almost sinecure place of lord privy seal, and, leaving the old scene of his glory, went to the Upper House as Viscount Pitt and Earl of Chatham. 'The joke here is,' wrote Lord Chesterfield to a friend on the occasion, 'that he has had *a fall upstairs*, and has done himself so much hurt that he will never be able to stand upon his legs again. Everybody is puzzled how to account for this step; though it would not be the first time that great abilities have been duped by low cunning. But, be it what it will, he is now certainly only earl of Chatham, and no longer Mr. Pitt in any respect whatever.'

We cannot enter into the history of the rickety administration thus attempted to be set up. Suffice it to say that it was in a state of confusion and embarrassment all the time it subsisted, and that Lord Chatham, its nominal head, was soon withdrawn from all share in the conduct of affairs by a serious illness, which, from the evidence furnished by his lately published correspondence, clearly appears to have been chiefly mental, and to have taken the form of a deep hypochondria, making him shrink with horror from business and from intercourse with any person beyond the circle of his own family. At last, on the 15th of October, 1768, he sent his friend Lord Camden to the king with a resignation of his office.

This decision, and the relief from responsibility which it brought with it, probably had a beneficial effect on his health. In the session of parliament which began on the 9th of January, 1770, he again appeared in his place, and took as prominent and active a part in debate as he had ever done in his best days. One of the chief questions on which he exerted himself in this and the next session was that of the conduct of the House of Commons in the affair of Wilkes's election for Middlesex, which he condemned vehemently and without reserve, and contended to be a flagrant outrage on the first principles of the constitution. He also appeared occasionally in the session which began 21st January, 1772; in one speech in particular, which he delivered in May that year, in support of a bill for the relief of Protestant Dissenters, he showed, according to the report of the debate, 'as much oratory and fire as perhaps he ever did in his life.' But his name does not appear again in the debates till towards the end of the session of 1774, on the 27th of May in which year, though still labouring under a state of ill-health, which had long kept him absent from the House, he spoke warmly and impressively in opposition to one of Lord North's bills for subduing the resistance in America. He spoke also several times on the same now all-engrossing subject in the earlier part of the first session of the next parliament, which met in November of this year; but then a return of ill-health sent him back for nearly two years into retirement. When he again made his appearance in the House, in the end of May, 1777, it was to reiterate with increased earnestness his views and warnings on American affairs; and he continued to come down for the same purpose during the next session as often as the little strength remaining in his racked and shattered frame would permit. At last, on the 7th of April, 1778, after he had spoken once on a motion for an address to the king on the state of the nation, he attempted to rise again to notice something that had been said by the duke of Richmond in reply, when he dropped senseless into the arms of those beside him. He was carried home to his house at Hayes, in Kent, but never again rose from his bed, and died on Monday, the 11th of May, in the seventieth year of his age.

All the enthusiasm which had been stirred by his name in former days was revived for the moment by the death, in circumstances so affecting, of the orator and statesman who for more than forty years had filled so large a space in the public eye, and whose memory was associated with so much of popular principle and national glory; and to a funeral and a monument in Westminster Abbey at the public expense, were added the more substantial rewards of a grant of twenty thousand pounds for the payment of his debts, and a pension of 4000*l*. a year to his descendants.

As to Lord Chatham's real claims, either as an orator, a minister, or a patriot, we may observe in general that in each of these capacities he appears to have been at best the man merely of his own time. His eloquence, of the immediate effects of which there can be no question, must have partaken very much of the only half-intellectual art of acting, and been indebted for its power to his voice, his eye, and other mere external advantages, as much as to any higher qualities. At least no report that has come down to us of any of his speeches conveys an impression at all answering to their traditionary fame. Earnestness and fervour there is, as well as clearness and distinctness, with occasional point or happy aptness of expression; there is generally forcible reasoning, and a luminous disposition of the subject; but that is nearly all. Lord Chatham's eloquence is rarely irradiated by any imaginative colouring, and is without any remarkable depth or novelty of thought; its ordinary rhetorical characteristic is tawdriness, and its vein of reflection common-place. Indeed it is probably to this last-mentioned quality that it was in great part indebted for its immediate success; it hit the popular or general understanding, as it were, between wind and water. And to this effect also contributed the thoroughly English character of Lord Chatham's mind; a proud love of his country was his master-passion, and her greatness and glory ever the object on which he kept his eye. He was also altogether a public man—amiable and beloved, indeed, in his domestic circle, and both enjoying and returning very cordially the affection of his family, but, as his enemies admitted, free from dissipation of every kind, and having as little of vice or indolence or any other kind of sensuality in his composition or habits as any man of his time. On the subject of his ambition indeed it would be easy to say much, as much has been said; and some of his letters lately published go to show that his love of power was combined not only with great haughtiness of bearing towards his inferiors, but also with no small degree of what would now at least be called subserviency to those above him. But even in regard to this last most unfavourable exhibition which he makes of himself, something is to be allowed for the manners and indeed established etiquette of the age, which in all departments of social intercourse exacted a degree of formality and ceremonious observance which now seems extravagant and ridiculous, and if practised in the present day would really indicate a much greater degree of servility than it then implied. It can hardly be disputed that Chatham, whatever faults he may have had, was essentially a high-minded man, and it is most reasonable, when we find him appearing otherwise in any particular case, to set down the defect as one of manner rather than of character.

The Life of Lord Chatham has been written by Almon, the bookseller, in 3 vols. 8vo., under the title of 'Anecdotes of the Life of the Earl of Chatham;' and much more accurately, as well as fully, by the Rev. Mr. Thackray, in his 'History of the Earl of Chatham,' 2 vols. 4to. Of his own writings nothing has been given to the world except a small volume of letters addressed to the son of his elder brother, afterwards Lord Camelford, which were published a few years ago by the late Lord Grenville, and his 'Correspondence,' in 4 vols. 8vo., which has only very recently appeared. The latter publication abounds in matter illustrative both of the life of Chatham and of the political history of his time. By his wife, who survived till 1803, besides two daughters, he had three sons, the political distinction acquired by one of whom, the subject of the next article, rivalled that of his illustrious father.

PITT, THE RIGHT HONOURABLE WILLIAM, second son of the first earl of Chatham, was born at Hayes, in Kent, 28th May, 1759. His elementary education was conducted at home, under the immediate care of the Reverend Edward Wilson, afterwards canon of Windsor, and anxiously superintended by his father, whose favourite he was, and who early formed high anticipations of the figure he would make in life. He was sent in 1773 to Pembroke Hall, Cambridge, where his studies were principally under the direction of Dr. Pretyman (who afterwards took the name of Tomline, and became bishop of Winchester, and the biographer of his distinguished pupil). 'Although he was little more than fourteen years of age when he went to reside at the university,' says Bishop Tomline, 'and had laboured under the disadvantage of frequent ill health, the knowledge which he then possessed was very considerable; and, in particular, his proficiency in the learned languages was probably greater than ever was acquired by any other person in such early youth. In Latin authors he seldom met with difficulty; and it was no uncommon thing for him to read into English six or seven pages of Thucydides, which he had not previously seen, without more than two or three mistakes, and sometimes without even one.' Mr. Pitt was probably very well taught when he came up to the university; but this way of stating the matter only shows that the bishop's own scholarship was small.

After leaving Cambridge, Mr. Pitt visited France, and studied for a short time at Rheims. On his return to England, being intended for the profession of the law, he entered himself of Lincoln's Inn; and he was called to the bar in 1780. But after having gone the western circuit only once or twice, he was returned to parliament for the borough of Appleby, the patron of which was then Sir James Lowther (afterwards earl of Lonsdale); and from this date his original profession was given up for the House of Commons and a political career.

He took his seat on the 23rd of January, 1781, and his first appearance in debate was on the 26th of February following, on the motion for the second reading of Mr. Burke's famous bill for the regulation of the civil list establishments. He gave his hearty support to the measure, 'and,' says the report, 'in a speech directly in answer to matter that had fallen out in the course of the debate, displayed great and astonishing powers of eloquence. His voice is rich and striking, full of melody and force; his manner easy and elegant; his language beautiful and luxuriant. He gave in this first essay a specimen of eloquence not unworthy the son of his immortal parent.' He afterwards spoke repeatedly on the side of the opposition in the course of this and the following session, before the termination of which it may be said that he had taken his place with Burke, Fox, and Sheridan (the last also a member of only the same standing with himself), in the front rank of the debaters of the day.

It was on the 7th of May, 1782, a few weeks after the fall of the North and the appointment of the second Rockingham administration, that Mr. Pitt made his first motion for the reform of the representation of the people. The motion was defeated by an inconsiderable majority; but the mover continued for some years after this to advocate, if not to hold, the principles or opinions which he announced on this occasion. At this date indeed he was so zealous a friend of reform as to take a leading part in some proceedings out of doors for the promotion of that object.

The death of the Marquis of Rockingham in the beginning of July having dissolved the administration of which he was the head, and that of Lord Shelburne having succeeded, Mr. Pitt was appointed to office and to a seat in the cabinet, as chancellor of the exchequer, having just entered his twenty-fourth year. This was the administration to which it was left to finish the contest that had arisen out of the attempt to tax the Americans, by acknowledging the independence of the United States, and concluding peace with France and Spain. It was assailed upon these and various other grounds by the famous coalition formed between the adherents of the two immediately preceding ministers, as respectively represented by Lord North and Mr. Fox; and the issue was, that in March, 1773, Lord Shelburne and his colleagues were driven from office by the united force of this new opposition, and a cabinet was formed, nominally under the premiership of the Duke of Portland, but in which the chief power was actually lodged in the hands of North and Fox, who were appointed secretaries of state. The alliance of whigs and tories however, which had carried this victory, was now opposed by another body of similar composition, formed by the Shelburne whigs and the tories who, seceding from North, professed themselves the friends and supporters of the court, which was well understood to bear with impatience the yoke of the new ministry. Of this opposition Pitt was the recognised leader in the House of Commons. Among other manœuvres to which he had recourse with the view of annoying and damaging the government, was the renewal of his motion for parliamentary reform. The effect, as had been anticipated, was to array Fox and North against each other in the debate and the division; but the motion nevertheless was negatived in rather a full house by a majority of nearly two to one. The serious opposition to the government did not begin till the next session, when Fox brought forward his India bill; but even that measure was carried through all its stages in the House of Commons by great majorities, and only encountered a formidable resistance when it reached the Lords, where all the personal influence of the king was exerted to procure its defeat. This object being attained, his majesty, with his characteristic decision, followed up his advantage by dismissing Mr. Fox and Lord North, when they would not resign, and by appointing Mr. Pitt prime minister, with the offices of first lord of the treasury and chancellor of the exchequer. This was in the middle of December, 1783.

The state of parties was now very extraordinary, and gave rise to the most remarkable contest in the history of parliament. In the House of Commons the force of the opposition very considerably outnumbered that of the government, even after all the impression that the influence of the crown had been able to make upon the ranks of the former; so that if the issue of the struggle had depended solely upon that assembly, it could not have been doubtful or long deferred. But, if Mr. Pitt had the representatives of the nation against him, he had decidedly the nation itself on his side, and with this, backed by the support of the crown, his position was impregnable, for, if it came to the worst, a dissolution could in a moment put an end to the existence of the present House of Commons, and secure another in accordance with the prevailing popular feeling. Such an appeal to the people however was for obvious reasons far from palatable to the crown, and not to be resorted to if it could be avoided, although in this case the circumstances were as favourable for such an experiment as they could ever be expected to be, the permanent body of the House of Lords, whose union with the Commons might have considerably strengthened the latter, being already ministerial by a steady though not a very large majority. Theoretically, indeed, the crown might have made a majority for itself in that branch of the legislature more directly than in the other house; but practically, a creation of peers for such a purpose would have been a more violent and unconstitutional measure than a dissolution in any circumstances, and, ventured upon contemporaneously with a dissolution, would have been a wholly unexampled stretch of the prerogative, the effect of which upon the public mind probably would have been to counteract all the good effects that were to be hoped for from the other expedient. The policy which Mr. Pitt adopted was very masterly, and it was carried out with a steadiness and courage which would have been wonderful in the most veteran statesman. He did not dissolve the parliament immediately, but first suffered the opposition to waste their strength and damage themselves in the public opinion to an infinitely greater extent than ever by a long succession of infuriated and unavailing attempts to drive him from office; and then, when, after a battle which lasted for three months, he had reduced their majority from between fifty and sixty to one, he sent them back to their several constituencies, to be one-half of them rejected at a new general election. About 160 of them in fact lost their seats, and were dismissed to private life, with little to console them in their retirement except the name they received of 'Fox's Martyrs.'

Mr. Pitt's biography from this date is little else than the history of the public affairs of the kingdom so long as he lived. He continued at the head of the ministry which this great victory had established in power, for about seventeen years—a most eventful and important period, in the course of which the relations of parties were altogether changed, and this country and Europe were suddenly and violently translated from a state of profound peace into the most general and most convulsive war that had been known in modern times. [Bonaparte; Burke; George III.] The elder Pitt, as we have seen in the last article, owes his chief fame as a minister to his conduct of the war in which he found the country involved on his first accession to power; but it has been generally thought unfortunate for his son's political reputation that he should have been transformed from a peace into a war minister. In point of fact, the nation certainly continued to make a very steady economic progress during the first nine peaceful years of his administration, and the military results of the last eight were on the whole decidedly disastrous. During the former period the trade of the kingdom was estimated to have increased by very nearly a third; and in the five years from 1783 to 1788, the revenue had received an augmentation of 5,000,000*l.*, of which not more than 1,500,000*l.* was calculated to have arisen from new taxes. At the same time the expenditure was not greater in 1790 than it had been in 1784, being in both years under 12,000,000*l.* The establishment of a new constitution for the East India Company (1784), the establishment of a new sinking fund (1786) [NATIONAL DEBT, xvi., p. 100], the arrangement of a commercial treaty with France on very liberal principles (1786), the consolidation of the customs (1786), acts passed for the relief of the Roman Catholics in England, Scotland, and Ireland (1791, 1792), besides various minor measures for the suppression of smuggling, were the administrative innovations that chiefly distinguished this period, and that were understood to owe their origin mainly to the premier. In 1785 Mr. Pitt also once more brought forward the subject of the amendment of the representation of the people in parliament; but he did not call in the aid of his authority as minister to ensure the success of his motion, which was negatived by a considerable majority, and which he never renewed. Afterwards, when the question of reform was taken up by the Society of the Friends of the People, and brought forward at their instance by Mr. (now Lord) Grey, the proposal found in Mr. Pitt one of its most determined opponents. To the exertions that were now begun to be made for the abolition of the slave trade, he lent the aid of his eloquence and of his own vote; but upon this question also he declined to use his power or influence as the head of the government. He took much the same course in regard to the prosecution of Warren Hastings, and the correction of the abuses of the Indian government. All the measures, it may be observed, to which Pitt gave only this kind of support, failed of success during his administration.

One of the most remarkable of the contests and victories that illustrate this first period of his government, occurred in the session of 1788-9, when he successfully maintained against Mr. Fox the right of parliament to supply the temporary defect of the royal authority occasioned by the incapacity of the reigning king—a right which seems to be now received as an established doctrine of the constitution.

Almost the only memorable legislative measure of the latter years of Mr. Pitt's first ministry was the union with Ireland, which was effected in 1799. It is now known that the disappointment of the expectations which he considered himself entitled to entertain of the abolition, or at least very great mitigation, of the penal and disabling laws affecting the Roman Catholics, was the reason which he assigned to the king for retiring from office soon after the passing of this measure. He and his friends resigned in March, 1801.

For some time Mr. Pitt gave his support to the administration of his successor Mr. Addington; but when the rapidly growing conviction of the incompetency of the new cabinet began to foretel its speedy downfall, he joined in the general cry against it, and the result was that in May, 1804, he became again prime minister. He remained at the head of affairs till his death, on the 23rd of January, 1806, the consequence partly of a wasted constitution, partly, it is generally believed, of a broken heart. The overthrow of the new coalition which he had succeeded in forming against France by the series of successes achieved by that power in the latter part of the year 1805, is supposed to have combined with the vexation arising from the impeachment of his friend Lord Melville to destroy him. He had for some years been accustomed to stimulate his overtaxed powers of body and mind by a lavish indulgence in wine; and this habit also no doubt had its share in shortening his days.

The public bearing of Mr. Pitt was cold and lofty; but he is said to have unbent himself very gracefully among his intimate friends, and the few who really knew him well seem to have been strongly attached to him. Whatever were his faults, there was no meanness in his character. As to the merits of his general system of administration, opinion is still nearly as much divided as ever. With regard to the character of his oratory there is perhaps beginning to be a more general agreement; and we may venture to say, without incurring the chance of any very loud or extended dissent, that, imposing and effective as it was at the moment of delivery, it owed its success as much to the impression which it made upon the ear, and to what we may call its mere mechanical qualities, as to any diviner inspiration. It wanted even the earnestness and occasional fire of his father's eloquence; and of either splendour of imagination or any remarkable depth or force of thought, it must be admitted to have been nearly destitute. Its highest quality appears to have been a power of sarcasm, which was the proper expression of a nature like that of Pitt, cold, proud, and contemptuous, and having little sympathy either with the ordinary vices and weaknesses, or with the better feelings and enjoyments, of his fellow-men.

PITTA, M. Vieillot's name for a genus of remarkable birds, placed by Mr. Swainson among the *Myiotherinæ*, or *Ant-Thrushes*. [MERULIDÆ, vol. xv., p. 122, where the generic character of the genus and that of the subgenera *Chlorisoma* and *Grallaria* are given.]

Pitta. (Vieill., Temm.)

M. Lesson remarks that, under the name of *Myiothera*, Illiger and Cuvier united the *Brèves* of Buffon and the *Ant-Thrushes* properly so called. These *Brèves* are remarkable, he observes, for the vivid colours of their plumage, their long legs, and their very short tail. They are only found, he adds, in the Malaisian Islands, whilst the *Ant-Thrushes* belong to the New Continent as well as to the Old World.

Mr. Swainson notices the genus *Pitta* as one of remarkable beauty, and observes that they have the gradually-curved bill of the true thrushes, but much stronger. 'The predominant colour of their plumage,' continues Mr. Swainson, 'is green, the sides of the head and wings being generally variegated with vivid blue; some species have a hood of black, and all are confined to New Holland and the neighbouring isles of the Indian Seas. America indeed presents us with a representation of these genera, in the subgenera *Grallaria*, Vieill., and *Chamæza*, Vig.; but the species are very few, and they are coloured in the homely hues of ordinary thrushes. To this group, as a subgenus, we refer *Chlorisoma*, called by some writers by the barbarous and unmeaning name of *Kitta*. The bill is clearly that of a thrush, while the legs place it among the *Myotherinæ* (*Myiotherinæ*), of which it seems to be the rasorial subgenus, both on account of its size, its crest, and its affinity to *Myophonus*. There are two or three species, all natives of India.'

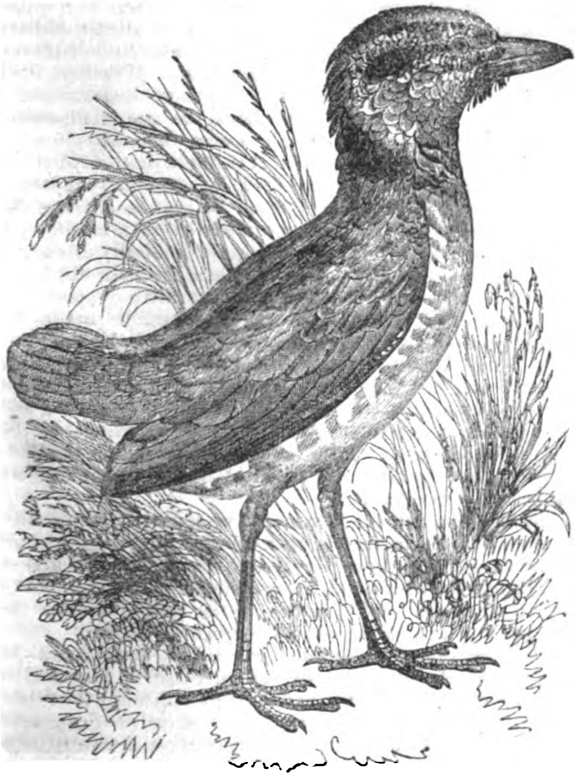
'The genus *Myothera*, on the other hand, is chiefly restricted to tropical America, and comprises numerous species of a smaller size, clothed in dark colours, but prettily variegated with white. Although distinctly separated from the Oriental group by their abruptly-hooked and strongly-toothed bill, they are yet so intimately allied to the small bush-shrikes (*Thamnophilinæ*) that it is almost impossible to draw a distinction between them.'

'Of all the tribes of insects which swarm in the tropics the ants are the most numerous; they are the universal devastators, and in the dry and overgrown forests of the interior the traveller can scarcely proceed five paces without treading upon their nests. To keep these myriads within due limits, a wise Providence has called into existence the ant-thrushes, and has given to them this particular food. Both are proportionate in their geographic range, for, beyond the tropical latitudes the ants suddenly decrease, and their enemies, the *Myotheræ*, totally disappear. As a general distinction by which this family may be known from the bush-shrikes, we may mention the difference in the feet,—the structure of one being adapted for walking, while that of the other is more suited for perching. The ant-thrushes are very locally distributed; for, although the group is tropical, we frequently found that a particular species, very common in one forest, was replaced in another by a second; while a third locality in the same district would present us with still another kind, different from those we had previously found. Cayenne and Surinam, in like manner, furnish us with many species totally unknown in the forests of Brazil.'

To return to *Pitta*. We select, as an example, *Pitta Gigas*, *Brève Geant*, or *Giant Pitta*.

Description.—Size equal to that of a magpie, but the tail is short and squared, and the wings cover it entirely. A very brilliant azure blue covers the back, the scapulars, the rump, and tail; a less vivid tint is spread over the wings, the quills of which are black, coloured with azure towards the tips; summit of the head, nape and demi-collar of the lower part of the neck black; feathers of the front and eyebrows ashy-brown; throat whitish; an ashy-brown tint is spread over all the lower parts; the feet are very long and of a horny ash-colour. Total length nine inches.

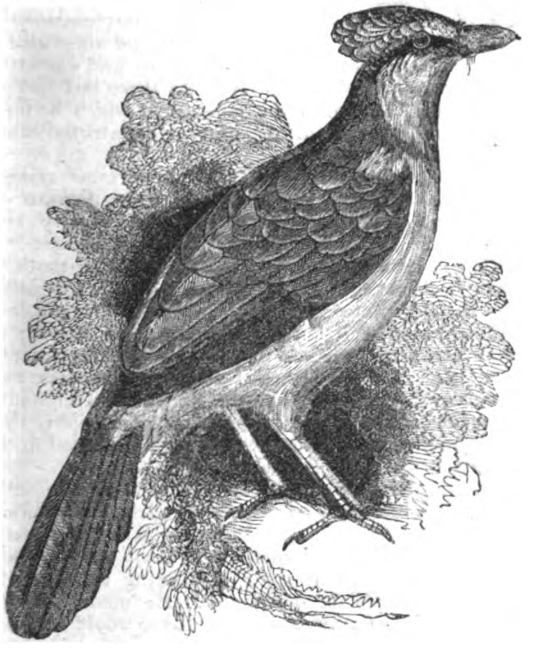
Locality.—Sumatra. (Temm.)



Pitta Gigas.

Chlorisoma. (Sw.)

Example, *Chlorisoma thalassinum* (*Kitta thalassina*, *Piroll Thalassin*, Temm.).



Chlorisoma thalassinum.

Description.—Greater part of the plumage very brilliant celadon-green; a velvety black band springs at the angle of the bill, passes backwards so as to include the eye, and surrounds the occiput; tail deep tarnished green, wings reddish, but the three or four secondary feathers nearest the body are opaline bluish ash; iris, bill, and feet very bright vermillion red. Total length eleven inches two or three lines.

The *male* and *female* have nearly the same livery.

The young of the year differ in the colour of their bill and feet, which are black; in that of the wings, which is a tarnished rusty red, and in the very clear blue, which is nearly whitish, of all the rest of the plumage. This blue tint is more vivid in middle age, and passes by degrees from bright azure blue to celadon-green. Individuals during moult have the plumage varied with these two tints very vivid and pure.

Localities.—Java and Sumatra. (Temm.)

Grallaria. (Vieill.)

Example, *Grallaria Rex* (*Roi des fourmilliers*, Buff.; *King Thrush*, Lath.; *Turdus Rex*, Gmel.).

Description.—Brown, inclining to red, lighter beneath; occiput plumbeous; forehead varied with black and white.

Locality.—South America, Guiana, and Brazil especially.

Grallaria Rex.

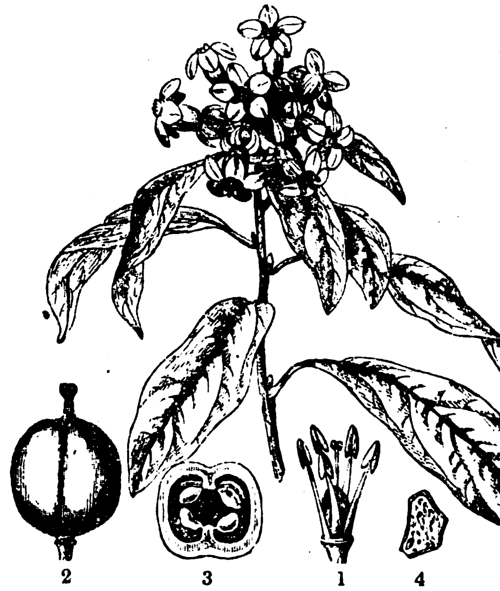
PITTACAL, one of the ingredients of wood-tar, and so named by Reichenbach, who discovered it, from *πίττα*, *pitch*, and *κάλλος*, *ornament*, on account of its fine colour. When a little barytes-water is added to impure picamar, or to oil of tar deprived of its acid, the liquor directly becomes of a fine blue tint, which very soon passes into the colour of indigo: like this pigment, it assumes a copper colour when rubbed, and according to its purity becomes afterwards golden or brass yellow.

Pittacal is inodorous, tasteless, and not volatile; at a high temperature it is decomposed and charred, but does not give out ammonia. It is suspended in water in so fine a state of division, that it passes through filters and gives a blue colour to the water, but it does not dissolve in it; light and air do not act upon it; it is insoluble in alcohol and æther; it dissolves in cold diluted sulphuric and hydrochloric acid; acetic acid also dissolves it readily, and the solution is of a fine red colour; alkalis restore the blue colour; nitric acid decomposes it. Reichenbach states that it is a more delicate test of acids and alkalis than litmus.

PI'TTACUS, one of the so-called seven wise men of Greece, was the son of Hyrradius, and born at Mitylene in the island of Lesbos, about the year 652 B.C. Nothing is known of his education and the early part of his life, and the first facts which his biographer, Diogenes Laertius, mentions are, that, with the assistance of the brothers of Alcæus, he delivered his native island from the tyranny of Melanchrus (B.C. 612), and that when the Mitylenæans were involved in a war with the Athenians about the possession of the town of Sigeum on the Hellespont, Pittacus gained the victory over the Athenian general Phrynon by a singular stratagem. He came into the field armed with a casting-net, a trident, and a dagger, and first entangled and then despatched his adversary (B.C. 606). In this war Alcæus left his shield a trophy to the enemy. It must have been soon after this war that Mitylene was distracted by the two political parties which about this time began to appear in various parts of Greece. The aristocratic party, to which Alcæus and his brother Antimenidas belonged, was driven from the town, and the popular party unanimously elected Pittacus to the office of æsymnetes to defend the constitution. During his administration, which lasted from 590 to 580 B.C., he overcame his adversaries, and gained them by his clemency and moderation. Even Alcæus, who had assailed him in his poems with the greatest bitterness, became reconciled. Pittacus regulated the affairs of his country by the most salutary laws and institutions, and in B.C. 580 he voluntarily resigned his office and withdrew from public life. Valerius Maximus (vi. 5, ext. i.) erroneously states that Pittacus was made æsymnetes at the time of the war with the Athenians for the purpose of conducting it: but this is sufficiently refuted by the authority of Strabo, the fragments of Alcæus, and Diogenes Laertius. Pittacus passed the last ten years of his life in quiet retirement, enjoying the esteem and love of the best and wisest of his countrymen; and when the Mitylenæans wished to reward him for his services with an extensive tract of territory, he refused to accept it for himself, but had it made consecrated ground, which to the time of Diogenes Laertius retained the name of the grounds of Pittacus. He died in B.C. 570, at the age of 82.

He was the author of a considerable number of elegies, of which a few fragments are still extant. Diogenes Laertius has preserved a short letter ascribed to Pittacus, and addressed to Crœsus, king of Lydia, which contains an answer to an invitation of the king to come to see his magnificent treasures. Many of the numerous maxims of practical wisdom current among the antients were ascribed to Pittacus, and are preserved in the works of Diogenes Laertius, Plutarch, Ælian, and others.

PITTOSPORA'CEÆ are polypetalous exogenous plants with a definite number of hypogynous stamens, a superior one- or two-celled ovary, which in the former case has parietal placentæ, numerous ovules, a single style, and hard seeds containing a very small embryo in the region of the hilum. Their position in a natural arrangement is unsettled, but appears to be near the Vitaceous order, rather than the Rhamnaceous or Polygalaceous. All the species contain in greater or less abundance a resinous substance, the use of which is unknown. Many of the species are pretty shrubs or bushes, sometimes extremely graceful, but they are of no known use. Most of them are natives of Australia. The names of Sollya and Billardiera recal to the mind some of the prettiest twiners of the greenhouse.



Pittosporum Tomentosum.

1, the stamens and pistil; 2, a ripe fruit; 3, the same divided transversely; 4, a section of a seed with the minute embryo near the base.

PITTS, WILLIAM. The very recent death of this highly-gifted artist prevents our attempting a biography, for which the materials are not yet collected. Still, rather than entirely pass over the name of one who will henceforth be known as one of the greatest among British artists, we content ourselves with giving a brief record of him.

He was born in London, in the year 1790, and brought up by his father to his own business, which was that of a chaser, or what would have been termed in Italy an *orefice*, a branch of art now regarded as little better than a mechanical one, and accordingly turned over almost entirely to artisans, although it was that in which Cellini displayed his mastery and earned his reputation. Whether Pitts subsequently studied under any sculptor we do not know.

His very early marriage, at about the age of nineteen, would seem to indicate that he was even then following his profession on his own account. It is likely that for what instruction in sculpture he ever had, he was chiefly indebted to Flaxman, for he was employed by him in chasing the shield of Achilles, designed and modelled by himself. Indeed there seems to have been great similarity of feeling and taste between Pitts and Flaxman, for both displayed their talents in poetical subjects and extensive compositions consisting of a number of figures. As a counterpart to the shield of Achilles by the one, may be placed the shield of Æneas by the other; also the shield of Hercules, from Hesiod, and the Brunswick shield, which is a large circular relief, representing George IV. in a car in the centre, and in the other compartments the principal events of the House of Hanover. Pitts was also employed on the Wellington shield, which was executed under the immediate inspection of Stothard.

By way of parallel to Flaxman's two series of designs from Homer and Dante, may be mentioned similar graphic compositions by Pitts from Virgil and Ossian, only the first of which has been engraved, being etched by himself in 1831; as yet they are hardly known to the public, whereas the designs of Flaxman are known throughout Europe.

Both for the exquisite fancy which they display and for their masterly graces of execution, some of his smaller subjects in relief have obtained for Pitts with many the title of the 'British Cellini.' Yet, except as indicative of congenial fancy and artistical power, such appellation is utterly inappropriate, hardly any two individuals being so utterly dissimilar in personal character as the arrogant and daring Benvenuto and the meek and unassuming William Pitts, who was an enthusiast entirely devoted to his own art, and utterly unskilled in the art of winning his way to popularity and fortune. Hence it is matter of regret rather than surprise that he should not have obtained patronage at all in proportion to his ability and his genius; or that he encountered many disappointments, and was latterly involved in embarrassments. How far these last had any share in impelling him to the fatal act by which he terminated his life, it is difficult to judge. He destroyed himself by poison, April 16, 1840.

The following is a list of his chief productions, arranged according to their dates:—The Deluge, 1823; Samson slaying the Lion; the Creation of Eve; Herod's Cruelty, 1824; a Chariot-race, 1826; the Pleiades; Shield of Æneas, 1828; the Rape of Proserpine, and the Nuptials of Peirithous, two bas-reliefs, about eight feet long, executed for Mr. Simmons, of the Regent's Park, 1829; the Brunswick Shield, 1830; the Apotheoses of Spenser, Shakspere, and Milton; and another series of reliefs in two of the drawing-rooms at Buckingham Palace, 1831; the Shield of Hercules, 1834; a long bas-relief or frieze of all the English sovereigns from the Conquest, 1837; a design for a masonic trophy, 1839; the Triumph of Ceres, and a small subject modelled in wax, exhibited at the Royal Academy, 1840.

Whatever difference of opinion may exist with regard to Pitts' talents, there can only be one opinion as to his enthusiastic devotion to his profession, when it is known upon good authority that he sometimes had not his clothes off for a fortnight together, snatching during all that while only short intervals for bodily rest. He used to observe that even a day of eminence as a sculptor would not be too dearly purchased by a life of anxious toil.

In addition to the works above enumerated, may be mentioned two of his latest performances, the 'Kemble Tribute,' presented to C. Kemble, Esq., and a vase, executed for her majesty, as a sponsal present by her, of exquisite design as to its general form, and poetically embellished with groups in relief, signifying Birth, Infancy, Instruction, Education, and Love.

PITTSBURG. [PENNSYLVANIA.]

PI'TYLUS. [TANAGRINÆ.]

PITYRIA'SIS (from πίτυρον, bran) is a disease of the skin in which irregular patches of the cuticle appear covered with thin bran-like scales or with particles of a fine white powder, which, as fast as they fall off, are succeeded by others. It may be regarded as a morbid excess of the natural process of desquamation which is constantly going on, and by which the old cuticle is removed from the surface of the body to be replaced by that of more recent formation. [NUTRITION.] The commonest form of this disease is that called Pityriasis capitis, or dandriff. It affects chiefly the scalp and eyebrows, and is most frequent in children, in whom it originates either from generally disordered health or from mere neglect of cleanliness. It occurs also on the face and sometimes on other parts of the body in adults and old persons after exposure to the sun or a cutting wind, and it usually accompanies the commencement of baldness. The only local treatment which is necessary or useful is frequent washing and the application of some mild and simple ointment.

In the other forms of Pityriasis the discolouration of the cuticle is a more prominent sign than its desquamation in fine scales. The P. versicolor occurs in the form of irregular yellow or light brown patches, which are chiefly situated on the front of the chest and abdomen, and are commonly called liver-spots or tan-spots. The extent and form which such spots present are infinitely various; but though they sometimes exist unaltered for several years, they rarely produce any inconvenience beyond a slight itching. The P. rubra is an aggravated form of the preceding; the spots are more or less brightly red, and are the seats of considerable irritation. In the P. nigra the essential part of the disease, which is of very rare occurrence, is the production of a cuticle of nearly a black colour. It may be doubted whether it deserves to be regarded as a variety of Pityriasis, or whether the few cases that have occurred are not merely examples of the production in Europeans of cuticle similar to that which belongs naturally to negroes and other coloured nations, and of which the formation has been observed as often on apparently healthy as on diseased skin.

PITYU'SÆ. [BALEARIC ISLANDS.]

PIUS I., a native of Aquileia, succeeded Hyginus as bishop of Rome, A.D. 142. Little is known of him. Several decretals have been attributed to him by Gratian, but they are generally considered apocryphal. Pius died in the year 157, and was succeeded by Anicetus.

PIUS II., Æneas Sylvius Piccolomini, born in 1405, at Corsignano in the state of Siena, succeeded Calixtus III. in 1458. He was a man of extensive learning, and had distinguished himself in the Council of Basle, A.D. 1431-39—that celebrated assembly which attempted earnestly, though with little success, the reformation of the Church, and in which Piccolomini acted as secretary, and of which he wrote a history, 'Commentarius de Gestis Basil. Concilii,' in two books, a very important work for the history of the Church. At that time Piccolomini was a strong advocate for the supremacy of the Council and its right to judge and even depose the pope, 'who,' he argued, 'ought to be considered as the vicar of the Church rather than as the vicar of Christ.' These tenets however were condemned by Eugenius IV., but the Council asserted its authority by suspending the pope from his dignity; and then began a long struggle, which terminated in an open schism, the Council deposing Eugenius and electing Felix V. [AMADEUS VIII.] Piccolomini was appointed secretary of the new pope or antipope, and was sent by him as his ambassador to the emperor Frederic III., who was so pleased with him, that he prevailed upon him to give up his precarious situation and accept the place of imperial secretary. Frederic afterwards sent him on several missions and loaded him with favours. Piccolomini was not ungrateful; he wrote several works in praise of his patron and in support of his imperial prerogative—'De Origine et Auctoritate Romani Imperii ad Fridericum III. Imperatorem, Liber Unus;' 'Historia Rerum Friderici III.;' 'De Itinere, Nuptiis, et Coronatione Friderici III. Commentariolus;' 'De his, qui Friderico III. Imperante, in Germaniam, et per totam Europam memorabiliter gesta sunt, usque ad annum 1458, Commentarius.' At last Frederic sent Piccolomini as his ambassador to Pope Eugenius. This was a delicate errand for him who had been one of the avowed antagonists of that pontiff; but he managed so well by his dexterity, his captivating address, and, above all, his eloquence, that the pope not only forgave him, but became his friend, and Piccolomini had hardly returned to Germany from his mission, when he received a papal brief appointing him apostolic secretary. He accepted an office congenial to his clerical profession, and also as the means of fixing his residence in Italy; but he still retained a lively sense of gratitude towards his Imperial benefactor. From that time a marked change took place in the opinions, or at least in the professions, of Piccolomini, and he became a stout advocate for the claims of the see of Rome. Meantime Eugenius died, A.D. 1447, and his successor, Nicholas V., was recognised by the Fathers of the Council of Basle, who, being forsaken by both the emperor and the French king, made their peace with Rome. Felix V. also having abdicated in favour of Nicholas, the schism of the Church was healed. Nicholas made Piccolomini bishop of Trieste, and afterwards of Siena, and sent him as nuncio to Germany and Bohemia, where he had several conferences with the Hussites, which he relates in his Epistles. (*Epistola* 130.) He had however the merit (rare in that age) of recommending mild and conciliatory measures as the most likely to reclaim dissenters to the bosom of the Church. He wrote a work on the history of Bohemia and the Hussites, in which he states fairly and without any exaggeration the tenets of that sect, as well as those of the Valdenses, which he calls 'impious,' but which are mainly the same that have since been acknowledged by the Protestant and Reformed churches throughout Europe. He relates the burning of John Huss and Jerome of Prague, and speaks of their fortitude, 'which,' he says, 'exceeded that of any of the philosophers of antiquity,' and he recapitulates literally their charges against the corruption of the clergy. (Æneæ Sylvii *Historia Bohemica.*)

In the year 1552, Piccolomini, being then in Italy, was present at the solemn coronation of Frederic III. at Rome, and delivered an oration to the pope in the name of that sovereign, whom he afterwards accompanied to Naples. On their return to Rome, he delivered another oration before the pope, the emperor, and other German and Italian princes, and the ambassadors of other European courts, for the purpose of exhorting them to form an effectual league against the Turks, who were then on the point of taking Constantinople. Piccolomini felt the great danger to Christian Europe from the rapid advance of the Ottoman conquerors, and his paramount object through the remainder of his life was to form a strong bulwark to protect Italy and Germany; but at the same time he was too well acquainted with the politics of the various Christian courts, and their selfish and petty jealousies, to expect much union in their councils, and he expresses his views and his doubts in a masterly manner in several of his Epistles.

Calixtus III., the successor of Nicholas V., made Piccolomini a cardinal, and in 1458, after the death of Calixtus, he was unanimously elected pope by the name of Pius II. His pontificate lasted only six years, but during this period he distinguished himself by promoting learning, by inculcating peace and concord among the Christian princes, and exhorting them to unite their efforts against their common enemy, the barbarous Turks. Machiavelli, a writer not very favourable to the court of Rome, says that 'Pius showed himself mindful above all of the welfare of Christendom and of the honour of the Church, independent of any private passion or interest of his own.' (*Storie Fiorentine*, b. vi.) The year after his election he convoked a congress of the ambassadors of all the Christian sovereigns to arrange the plan of a general war against the Ottomans. The pope himself repaired to Mantua, accompanied by the learned Philelphus, who spoke eloquently in favour of the proposed league. Most of the Italian states were willing to join in it, but Germany and France stood aloof, and nothing was decided. Pius assisted Ferdinand, king of Naples, in his war against the duke of Anjou, the pretender to that crown. At the same time he was obliged to make war in his own states against Sigismondo Malatesta, lord of Rimini, and against the Savelli and other feudal barons, and he was successful. By a bull addressed to the universities of Paris and of Cologne, Pius condemned his own writings in defence of the Council of Basle, concluding with these words: 'Believe what I, an old man, now say to you, and not what I wrote when I was young; believe the pontiff rather than the private individual; reject Æneas Sylvius, and accept Pius II.' (*Bulla Retractionum omnium Dudum per eum in Minoribus adhuc agentem pro Consilio Basiliensi et contra Eugenium summum Pontificem Scriptorum*, Colonia, 1468.) In several of his letters to his friends also, and especially to Pietro di Noceto, he expresses sorrow for his juvenile weaknesses, for he had once been too fond of the fair sex, and had even written accounts of some of his amorous adventures and of those of other persons, which are found among his Epistles.

A vacancy having occurred in the archiepiscopal see of Mainz, two candidates appeared for it, Adolph, count of Nassau, and Dietrich of Isemberg. The latter had the majority of votes, but Pius, who by the concordat had the right of deciding in cases of contested elections, refused to confirm the choice of Dietrich unless he engaged not to assert the supremacy of a general council, not to convoke of his own authority an imperial diet, and further to pay to Rome double the sum fixed for the annates, or first fruits. Dietrich demurred to the first two conditions, and positively refused to accede to the last, and as proceedings were instituted against him in the apostolic court, he appealed to the next general council. Pius declared such appeals to be heretical, and excommunicated and deposed him, appointing Adolph of Nassau in his place. The emperor acknowledged Adolph, but Dietrich being supported by the Count Palatine and the elector of Bavaria, a war ensued, which, after much mischief, ended in the submission of Dietrich. Those who remembered the sentiments of Piccolomini when imperial secretary, and especially his letter (*Epistola* 25) to the Papal nuncio John Carvaia, concerning the supremacy of the council, were inclined to think that change of station had, in him as well as in most men, produced a corresponding change of opinions. Pius took also the pains to write a long letter to Sultan Mahomet II. to convince him of the errors of Islamism, and to induce him to turn Christian.

In the year 1464 an armament intended against the Turks was directed to assemble at Ancona, and soldiers began to repair thither from various parts. Matthias, king of Hungary, and Charles, duke of Burgundy, had promised to be of the expedition. The Venetians also had promised the use of their fleet to forward the troops across the Adriatic into Albania. Pius II. set off from Rome for Ancona, but on arriving there he found that the soldiers were in want of arms, clothes, and provisions; the foreign princes did not come; and instead of the Venetian fleet, only a few galleys made their appearance. The aged and disappointed pontiff fell ill, and on the 14th of August he expired, after having taken leave of his cardinals and begged forgiveness if he had erred in the government of the church. He was generally regretted, especially throughout Italy. He was succeeded by Paul II. Pius II. before his death raised his native town, Corsignano, to the rank of a bishop's see, and gave it the name of Pienza, by which it is now known.

As a learned man and a writer he is best known under the name of Æneas Sylvius, the most important part of his career being passed before he was elected pope. He was one of the first historians of his age, a geographer, a scholar, a statesman, and a divine. He was also a great traveller by sea and by land: he lived many years in Germany, he repeatedly visited France, went to Great Britain and as far as Scotland, and to Hungary. His biographer, Campanus, bishop of Arezzo, speaks at length of his peregrinations, and his diligence in informing himself of everything worth notice in the countries which he visited. His principal works, besides those already mentioned, are: 1, 'Cosmographia, vel de Mundo Universo Historiarum,' liber i. (a second book treats especially of Europe and its contemporary history); 2, 'In Antonii Panormitæ de Dictis et Factis Alphonsi Arragonum Regis, libros quatuor, Commentaria;' 3, 'Epitome supra Decades Flavii Blondi Forliviensis, ab inclinatione Imperii usque ad tempora Johannis XXIII., Pont. Max.,' in 10 books; 4, 'Historia Gothica,' published first at Leipzig in 1730; 5, 'A Treatise on the Education of Children, with Rules of Grammar and Rhetoric;' 6, lastly, his numerous 'Epistles,' which contain much varied information. A collection of his works was published at Basle: 'Æneæ Sylvii Piccolomini Senensis Opera quæ extant,' fol., 1551; but this edition does not include all. Domenico de Rossetti has published a catalogue of all his works and their various editions, and also of his biographers and commentators: 'Serie di Edizioni delle Opere di Pio II., o da lui intitolate,' Trieste, 1830. Biographies of Pius II. by Platina and Campanus are annexed to the Basle edition of his works, but a much more ample biography is found in the Commentaries published at Frankfort, 1614, under the name of John Gobellinus, his secretary, but which are known to have been written by himself or under his dictation: 'Pii II., Pont. Max., Commentarii Rerum Memorabilium quæ Temporibus suis contigerunt,' libr. xii., with a continuation by his intimate friend James Ammanato, cardinal of Pavia, who had, at his desire, assumed the name of Piccolomini.

PIUS III., Cardinal Francesco Todeschini Piccolomini of Siena, descended from a sister of Pius II., was elected pope in 1503, after the death of Alexander VI., and died himself in less than a month after his election.

PIUS IV., Giovanni Angelo Medici, or Medichini, of Milan, not of the great Florentine family of Medici, succeeded Paul IV. in 1560. He made his nephew Charles Borromeo a cardinal, who afterwards became celebrated as archbishop of Milan. He instituted proceedings against the nephews of the late pope, Cardinal Carlo Caraffa, and his brother the duke of Paliano, who were accused of various crimes, which were said to be proved against them, and both were executed. But in the succeeding pontificate of Pius V., the proceedings being revised, the two brothers Caraffa were declared to have been unjustly condemned. At Easter, 1561, Pius re-assembled the Council of Trent, which had been prorogued under Paul III. He was particularly intent upon checking the spread of heresy, which had taken root in several parts of Italy, besides the valleys of Piedmont, and especially in some districts of Calabria. The Spanish viceroy of Naples sent his troops, assisted by an inquisitor and a number of monks, to exterminate by fire and sword the heretics of Calabria. Emmanuel Philibert, duke of Savoy, after attacking with an armed force the Valdenses, who made a gallant resistance, agreed to allow them the exercise of their religion within their own districts, subject to certain regulations. The quarrels between the Catholics and Protestants, in France, were more difficult to settle. Some of the French Catholic prelates, among others Monluc, bishop of Valence, and the cardinal of Lorraine, recommended large concessions to be made to the Protestants with the hope of reconciling them to the church, and Queen Catherine de' Medici wrote to the pope to that effect. The pope referred the matter to the council, and in the meantime Catherine published the edict of pacification, in January, 1562, which allowed the Protestants liberty of conscience, and leave to perform their worship in country places, but not within walled towns.

The prelates sent by France to the Council of Trent, and several councillors of the parliament of Paris who were also ordered to attend in the name of the king, spoke loudly of the necessity of an extensive reform in the church, and seemed disposed to render the bishops more independent of the see of Rome. The cardinal of Lorraine was of opinion that the mass and other offices should be performed in the vulgar or popular language of each country; but the Italian prelates, and Lainez, general of the Jesuits, supported the maintenance of the established form of worship, as well as of the papal authority in all its existing plenitude. The discussions grew warm, and it was only in the following year, 1563, that the two parties came to an understanding. [TRENT, COUNCIL OF.] The council terminated its sittings in December of that year, and the pope confirmed its decrees by a bull. This was the principal event of the life of Pius IV. He died in December, 1565. His disposition was generous; and he embellished Rome; but he was charged with the common fault of nepotism.

PIUS V., Cardinal Michele Ghislieri, a native of Alessandria in Piedmont, and a Dominican monk, succeeded Pius IV. in 1566. He had distinguished himself by his zeal in support of the Inquisition, of which tribunal he was one of the leading members. At the same time he was austere in his morals, and wished to enforce a strict discipline among the clergy, and especially the monks and nuns, more than fifty thousand of whom are said to have been at that time living and strolling about Italy out of their respective convents, regardless of any of the obligations enjoined by their order. (Botta, *Storia d' Italia*, b. xii.) There was also a monastic order in Lombardy called the 'Umiliati,' possessed of considerable wealth, the heads of which led openly a most dissolute life, and even kept bravoes, or hired assassins, to execute their mandates. Charles Borromeo, archbishop of Milan, who endeavoured to check these atrocities, was shot at by one of the monks while at prayers in his oratory. The ball however only grazed the skin: the assassin was taken, and revealed his employers; and several preposti, or superiors of convents of the Umiliati, were executed. Pius V., having examined the whole affair, suppressed the order, and gave their property to the Jesuits and other orders.

Pius V. enforced the authority of the Inquisition over all Italy. There were at that time in several towns, especially in Tuscany, some scholars and other men of learning who advocated the doctrines of the Reformation. Some ladies also of high rank, who enjoyed a reputation for learning, such as Vittoria Colonna, Giulia Gonzaga, and Margaret, the wife of Emmanuel Philibert, duke of Savoy, were suspected of a similar bias. Pius demanded of Cosmo, duke of Florence, the person of Carnesecchi, a Florentine nobleman who made a public profession of opinions considered as heretical; being given up to the Inquisition, he was put to death at Rome. The same happened to Palearius, Bartocci, and Giulio Zanetti; the last, who was at Padua, being given up to the pope by the Venetian senate, on the plea that he was a native of Fano and a subject of the Papal State. Numerous informers were kept by the Inquisition in every town of Italy; and such was the terror produced by these severities, that the university of Pisa became almost deserted both by teachers and students. The pope also enforced the strict observance of the index of forbidden books, and enacted severe penalties against those who printed or introduced or kept such books. The printing-presses of Italy, those of Giunti of Florence, and others, declined greatly in consequence, and many printers emigrated to Switzerland or Germany. Pius V. enforced the canons against those priests who kept concubines; but instead of leaving to the civil magistrates the repression of this abuse, he insisted upon the bishops acting both as magistrates and judges, by means of armed men attached to their episcopal courts, and of prisons for the same purpose. This gave rise to frequent collisions between the secular and the ecclesiastical authorities, especially at Naples and Milan. Similar disputes took place concerning the ecclesiastical inspectors and collectors sent by the pope to visit and demand accounts of all church property throughout Italy. Pius proceeded on the principle asserted in the false decretals, that the pope has the disposal of all clerical benefices throughout the world. He also reproduced the famous bull called 'In cœna Domini,' which excommunicates all princes, magistrates, and other men in authority, who in any way favour heresy, or who attempt to circumscribe the ecclesiastical jurisdiction, spiritual and temporal, or to touch the property or revenues of the church; and all those who appeal from the decision of the pope to the general council, as well as those who say that the pope is subject to the council. He ordered this bull to be read every Thursday before Easter in every parish church throughout the Christian world. France, Spain, and the emperor of Germany strenuously resisted the publication of this bull. In Italy the senate of Venice likewise forbade its publication. At Naples and Milan the Spanish governors did the same, but the bishops and monks refused absolution to those who in any way opposed the bull. After much altercation and some mischief, the civil power attained its object, and the bull was set aside. In Tuscany the bull was allowed to be published, but rather as a matter of form than as a measure upon which judicial proceedings could be grounded. The monks and some of the parochial clergy however pretended by virtue of the bull to be exempt from all taxes, and refused the sacrament to the collectors and other revenue officers and their families. The duke of Florence, Cosmo de' Medici, threatened to put the monks in prison and prosecute them. The Tuscan bishops tried to conciliate matters, and to repress the arrogance of the clergy, but the disturbances continued till the death of Pius V. (*The famous Bull 'In Cœna Domini,' published at Rome every Maundy Thursday, against Heretics and all Infringers of Ecclesiastical Liberties*, with a *Preface*, London, 1689.)

By a bull dated August, 1569, Pius created Cosmo de' Medici, who till then had only the title of duke of Florence, grand-duke of Tuscany, and his successors after him, and sent with the bull the model of a crown, ornamented with a red lily, the former ensign of the Florentine republic. Pius was a great promoter of the Christian league against the threatening arms of the Ottomans. After the glorious naval victory of the Curzolari, or of Lepanto, won by the Christian combined fleet against the Turks, in September, 1571, Pius caused Marcantonio Colonna, commander of the Papal galleys, who had distinguished himself in the battle, to make his triumphal entrance into Rome on horseback, preceded by the Turkish captives and spoils, and accompanied by the magistrates, noblemen, and heads of trades of the city of Rome. He ascended the Capitol, and thence proceeded to the palace of the pope, who received him with great honour. The whole scene was like a renewal of the antient Roman triumphs. Pius V. died of the stone, in May, 1572. He was austere and intolerant in his religious opinions, but he was sincere and disinterested, and of unspotted morals; he was learned, and a friend to learning, provided it did not encroach upon matters of belief. It is said that when some one told him that the people of Rome were dissatisfied with the austerity of his discipline, he answered, 'They will be still more grieved at my death:'—and so it was; for that fickle people crowded round his dead body, endeavouring to touch his garments, as if they were relics. The Roman church has numbered Pius V. among its saints. He was succeeded by Gregory XIII.

PIUS VI. (Cardinal Angelo Braschi), a native of Cesena, was elected pope in 1774, after the death of Clement XIV. He was then fifty-five years of age, and had the reputation of being of a generous disposition, and fond of learning and the arts. He had also, besides the advantages of a handsome person, a graceful demeanour and easy and affable manners. In his previous office of treasurer he had managed the financial affairs of the country with wisdom and disinterestedness. The choice of such a man was generally approved. One of the new pope's first acts was to allow greater comforts and indulgence to Father Ricci, the general of the suppressed order of Jesuits, who had been confined in the castle of St. Angelo for some years, though nothing was ever proved against him. Ricci died shortly after, in his place of confinement, in November, 1775, and the pope ordered his remains to be interred in a solemn manner. [Jesuits.]

In 1777, Pius VI. had a serious dispute with Leopold I., grand-duke of Tuscany, and Ricci, bishop of Pistoja, on the subject of some grave moral offences which had been discovered in several convents. [Leopold II. of Germany, and I. of Tuscany.] The question of jurisdiction was at last settled, but it left a coldness between the courts of Rome and Tuscany. A more important disagreement took place between the pope and Joseph II., Leopold's brother, and emperor of Germany. Joseph was busy in suppressing superfluous convents, and emancipating the clergy of his dominions from the supremacy of Rome in matters of discipline. The principal points upon which the emperor insisted were the following:—that the monks should be subject to the jurisdiction of the bishops of their respective dioceses; that the bulls 'Vineam Domini' and 'Unigenitus,' and all other proceedings against the Jansenists, should no longer be quoted as authority; that in the universities and colleges of the Austrian states the Roman doctrines of the infallibility of the pope, of his temporal supremacy over secular princes, and his superiority over general councils, should no longer be taught. Pius VI. perceived in these reforms of Joseph II. a design to weaken the power and influence of the see of Rome, and he determined to make an effort to turn the emperor from his purpose. Accordingly he set out for Vienna in 1782, to visit the emperor, and to converse with him personally on the matters in question. For several centuries no pope had left Italy, and this movement of Pius VI. attracted universal attention. Monti wrote a poem on the subject, entitled 'Il Pellegrino Apostolico.'

Pius was received at Vienna with every honour; but he made little impression on the emperor, who referred the matter in discussion to his ministers, who were not favourably disposed towards Rome. The pope returned to his capital in disappointment, and was censured by many for having lowered the dignity of the holy see without obtaining any good result. Next came the synod of Pistoja, which was assembled by the bishop Ricci in 1786, and passed several propositions that were considered highly censurable at Rome, such as that every bishop holds his authority from Christ direct, and independent of the pope; that he should every two years convoke a synod of the parish incumbents of his diocese; and that a national council should be assembled whenever any serious controversy or doubt occurs in a country concerning either a matter of faith or discipline. Ricci went still further, for he openly spoke against indulgences: he maintained that the liturgy should be in the popular language of each country; and he approved of the four articles of the Gallican church established by the clergy of France in 1682. Pius condemned these propositions by a bull, and suspended bishop Ricci from his functions; but Ricci, being supported by his sovereign, continued in his see. Ricci was in reality a Jansenist, but he was not a heretic: he proposed to restore the antient discipline of the church. He was a zealous Catholic in matters of dogma, and he was even remarkably strict in enforcing the fasts and abstinence from meat on certain days prescribed by the church.

Pius VI. was also busily employed in other matters besides controversy. He undertook and partly effected, through the direction of the engineer Rapini, the draining of the marshy region, containing near two hundred square miles, called the Pomptine marshes, by which a considerable proportion of it was made cultivable. He restored the antient Via Appia, which had become impassable, and built villages and post stations along the same. He also restored the port of Terracina, and adorned it with handsome buildings. He greatly enlarged the museum of the Vatican, which he made one of the richest in Europe in works of sculpture, vases, precious marbles, and other remains of antiquity; and he caused a splendid set of engravings of the objects in this museum to be published, under the title of 'Museo Pio Clementino.' He made additions to the church of St. Peter's, and embellished Rome with new palaces, fountains, and other structures.

The internal administration of Pius was liberal and mild. An unusual freedom of opinion and speech prevailed at Rome, a number of learned men gathered thither from other parts of Italy, many foreigners came to settle in that capital, the fine arts were encouraged by the pope and by several of the cardinals, and modern Rome had perhaps never been, since the times of Leo X., so brilliant and so pleasant a residence as it was under the pontificate of Braschi. But the storms of the French revolution darkened the scene, and rendered the latter years of Pius as gloomy and calamitous as the earlier part had been bright and prosperous. In the first period of that revolution, Pius VI. solemnly condemned the abrupt changes made in France concerning the discipline and the property of the clergy; but with regard to general or secular politics he showed great temperance. He even encouraged a man of learning, Spedalieri by name, to publish, in 1791, a work entitled 'I Diritti dell' Uomo' (the Rights of Man), in which the author openly condemns despotism, and asserts that a nation has the right of deposing a sovereign who abuses his authority, and he confirmed his doctrines by the authority of Thomas Aquinas, in his work 'De Regimine Principum,' addressed to the king of Cyprus. But, unlike Paine and the other expounders of the rights of man in France, Spedalieri maintains that the Christian religion is the surest, nay, the only guarantee of the rights of man and of civil freedom, and that social institutions, though they are the work of man, ought to be conformable to the Divine laws as revealed to us in the Scriptures. The work of Spedalieri was dedicated to Cardinal Ruffo, treasurer of the apostolic chamber, and Pius VI. rewarded the author with a stall in the chapter of St. Peter's.

An accident which occurred at Rome in January, 1793, widened the breach already existing between France and Rome. A young man, Hugo Basseville, an agent of the French republican party, being on his way to Naples, where he had been appointed secretary of embassy, made a foolish demonstration in the Corso, or high street of Rome, apparently to sound the opinions of the people. He appeared in a carriage with several tricoloured flags, and distributed revolutionary tracts, vociferating something about liberty and against tyrants; but he soon found that the people of Rome were not prepared to listen to him. A mob was collected; he rushed out or was dragged out of his carriage, and mortally stabbed in several places by the populace. The military came to the spot, but too late; some of the murderers were taken and tried; and yet the papal government, though innocent of the fact, was charged by the French Convention as being a party to it. [Monti.] The pope then joined the league of the sovereigns against France, and strengthened his military establishment.

When General Bonaparte invaded Northern Italy in 1796, he took possession of the legations, but at the same time offered to the pope conditions of peace. After some negotiation, the pope refused to submit to the onerous conditions imposed on him by the Directory. Bonaparte, who was then threatened by fresh armies from Austria, openly blamed the Directory for their harshness towards the court of Rome, saying that was not the way to make friends in Italy, and he spoke very highly of several cardinals and prelates with whom he was in friendly intercourse. (*Correspondence of General Bonaparte*, Letters of the 8th October, 1796, and 1st of January, 1797.) Meantime however he took possession of Ancona and Loreto, after defeating the papal troops on the banks of the river Senio; but the pope having sent envoys to sue for peace, Bonaparte granted it to him at Tolentino upon more moderate conditions than might have been expected. After the peace of Campoformio (October, 1797) and Bonaparte's departure from Italy, the agents of the Directory added vexation to vexation against the unfortunate pope, who, old and infirm, was unequal to the difficulties which crowded upon him. The papal treasury being drained, in order to pay the contribution of thirty millions of livres (1,200,000*l.*), the pope was obliged to seize the deposits in the Monte di Pietà, by which many families lost all they had. A tragical incident hastened the catastrophe. On the 28th December, 1797, a small band of revolutionists of Rome and other parts of Italy, with some Frenchmen among them, among whom was General Duphot, who was attached to the French embassy at Rome, having dined together in the palace of the French academy of the arts, and being heated with wine, took into their heads to renew the former attempt of Basseville. Raising the tricoloured flag, they sallied into the streets, calling out that they were going to hoist the ensign of liberty on the Capitol. A body of military came to disperse them, which was effected at first without bloodshed; but the fugitives ran to the palace of the French ambassador, followed by the soldiers, who fired and wounded some of the insurgents. The remainder rushed into the vestibule and court of the palace. The papal soldiers halted outside, but being provoked and mocked by those within, they rushed into the court, in order to clear it of the insurgents. The ambassador then made his appearance on the great staircase, in company with General Duphot, to appease the tumult. The soldiers cried out that the rebels should immediately quit the palace; but Duphot, who was young and hasty, drew his sword and encouraged the insurgents to drive the papal soldiers out of the court. The soldiers then fired, and Duphot, with several of the insurgents, fell. This affray was by the French Directory made the pretext for invading Rome and dethroning the pontiff, a thing on which they were bent, and would have effected long before, had it not been for Bonaparte's cooler policy. After issuing manifestoes in the usual style of those times, calling in plain terms the court of Rome a nest of assassins, the Directory ordered Berthier to march upon Rome. The pope gave orders that no opposition whatever should be made, as it would only serve to aggravate the evil. On the 10th February, 1798, Berthier entered Rome with his army, took possession of the castle St. Angelo, and went himself to live in the Quirinal palace. Pius VI., forsaken by most of the cardinals, who had escaped, remained in the Vatican. On the 15th of the same month a crowd of men assembled on the Campo Vaccino, dragging with them a tree which they styled the tree of liberty, and fixed it in the ground with a red cap on the top of it. Some of the leaders then began to ask the multitude what they wanted, and the answer was, that they wished to live free in a republican form, without any pope. The leaders gravely asked 'whether that was the will of the Roman people;' which was answered by acclamations in the affirmative. Five notaries then drew up a solemn act to that purpose, which was taken to Berthier. The French general ascended the Capitol, followed by a large retinue of officers, and proclaimed the Roman republic 'the sister and ally of France,' and said something in praise of 'the descendants of the Brutuses and the Scipios.' Songs, illuminations, and balls concluded the ceremony. Berthier afterwards sent an officer to intimate to the pope that he must renounce his temporal sovereignty. Pius answered, that he had received it from God and by the free election of men, and could not renounce it; that he was eighty years old, and his troubles could not be of long duration, but that he was determined to do nothing derogatory to his high office. Next came the commissary-general of the French army, who, after taking an inventory of all the valuables that still remained in the papal residence, ordered Pius to prepare to set out in two days. The pope said he could not oppose force, but protested against this new act of violence. On the 20th of February, Pius VI. left the Vatican with a few attendants, and, escorted by a strong detachment of cavalry, took the road to Florence. He was lodged first in a convent at Siena, and afterwards in the Carthusian convent near Florence, where he remained till the following year, when the French, having driven out of Tuscany the grand-duke Ferdinand, and being threatened by the Austro-Russians, who were advancing to the Adige, ordered the pope to be transferred to France. They took him to Pignerol, and from thence, in the month of April, the old pontiff was made to cross the Alps in a litter by the pass of Mount Genèvre, which was covered with deep snow, to Briançon. From thence he was taken to Grenoble, and afterwards to Valence on the Rhône, where he died, in August of that year (1799), in the 82nd year of his age and the 24th of his pontificate. Just before his death the Roman republic had ceased to exist, the French being driven out of Italy by the Austro-Russians, and Rome was occupied by Austrian and Neapolitan troops. The short period of the so-called republican government, enforced by French bayonets, was one of unspeakable distress for the people of Rome: dearth, exactions, suspension of commerce, and consequent poverty, overbearing military rule, authorised licentiousness, and general confusion of society, were the characteristics of that time.

In the year 1802, after the restoration of the papal government, the remains of Pius VI. were transferred to Rome by leave of the first consul Bonaparte, at the request of his successor Pius VII., and deposited with solemn pomp in the church of St. Peter.

(Botta, *Storia d' Italia*.)

PIUS VII. (Cardinal Gregorio Barnaba Chiaramonti) was born in the year 1742, of a noble family of Cesena, which is supposed to have been originally a branch of the French house of Clermont. He first studied in the college of Ravenna, and subsequently entered the order of Benedictines, in 1758. He was appointed lecturer on philosophy, and afterwards on theology, to the novices of his order, first at Parma and then at Rome. Pius VI. appointed him bishop of Tivoli, and in 1785 made him a cardinal and bishop of Imola. When Bonaparte took possession of the legations, and annexed them to the Cisalpine republic, Cardinal Chiaramonti in a homily exhorted his flock to submit to the new institutions, and to be faithful to the state of which they had become a part. This conduct is said to have acquired him the good opinion of Bonaparte. When the news of the death of Pius VI., in his exile at Valence, in August, 1799, came to Italy, the conclave being summoned to assemble at Venice, then under the dominion of Austria, as Rome was in a state of anarchy, Cardinal Chiaramonti repaired to the former city. Thirty-five cardinals assembled at Venice, in the Benedictine convent of S. Giorgio Maggiore, in order to elect a new pope, a dignity apparently not very enviable in those troubled times. The deliberations of the conclave lasted several months, and at last Cardinal Chiaramonti was chosen, on the 14th of March, 1800, and crowned pope on the 21st of the same month, under the name of Pius VII. In the following July the pope made his entrance into Rome, and soon after appointed Cardinal Consalvi his secretary of state, or prime minister. [Consalvi.] In the following year the peace of Luneville, between France and Austria, was made, and Bonaparte, first consul of France, ordered his troops to evacuate the Papal territories, with the exception of the legations, which had been formally incorporated with the so-called 'Italian Republic.' Meantime the ecclesiastical affairs of France were in a state of the greatest confusion. France was still nominally Roman Catholic, but the clergy were no longer in communication with the see of Rome, and were divided into parties. One party consisted of those who had sworn fidelity to the republican constitution, and were called 'Prêtres assermentés,' or 'constitutionnels;' another was composed of those who protested against the changes that had taken place in the administration of the church since the Revolution, and were called 'insermentés,' or 'réfractaires.' Each party had its bishops, who were in a state of schism towards one another. Many dioceses had no bishops, and others had two; some of the constitutional priests were latitudinarians in principle as well as in practice; others had married, contrary to the canons of the council of Trent; and others professed Jansenist principles. The refractory priests were generally soured by their past sufferings, were intolerant by principle, and provoked persecution against themselves rather than acknowledge the liberty of conscience which the government had proclaimed. In the midst of this confusion about one half of the population of France followed no mode of worship, and professed no religion whatever. A vast number of parish churches were shut up, and had been so for ten years. (Jauffret, *Mémoires sur les Affaires Ecclésiastiques de France*, vol. i.; Thibaudeau, *Mémoires sur le Consulat.*) Bonaparte wished for a concordat with Rome. The pope appointed the prelate Spina and the theologian Caselli, who proceeded to Paris, and Bonaparte named his brother Joseph, Cretet, councillor of state, and Bernier, a Vendéan priest, to treat with the pope's negotiators. At the same time Bonaparte, who was not himself much acquainted with ecclesiastical controversy, listened willingly to the advocates of the various parties. Grégoire, bishop of Blois, one of the leaders of the constitutional clergy, was opposed to the concordat. According to him, the church had no need of it: 'She had done without it for twelve centuries; the canons of the first four Œcumenical councils were sufficient for its administration. Vacancies to the sees should be filled up by election, by the bishops of the province, under the presidence of the metropolitan. The Gallican church ought to be untrammelled by Roman jurisdiction.' (Gregoire, *Essai Historique sur les Libertés de l'Eglise Gallicane.*) Others advised Bonaparte to proclaim unrestricted religious freedom and liberty of worship. (De Pradt, *Les Quatre Concordats.*) Others told him that he had in his hands the most favourable opportunity of shaking off the power and influence of the Roman see, and establishing in France a reformed religion. 'A vast number of people agreed about the necessity of having one established mode of worship, and most of the large proprietors were of this opinion, not that they were religiously inclined, but because they looked upon religion as the safest guarantee of their property. They wished to see an end of ecclesiastical anarchy, and if the first consul had thought proper to change the religion of France, he would have found not a few to support him.' (Jauffret, *Mémoires sur les Affaires Ecclésiastiques.*) But Bonaparte considered that if he were to proclaim the reformed communion, he would have one half of France against it, whilst of the other half only a small part would support him in earnest. He preferred therefore to be with the decided majority, as affording an easier means of government. Bonaparte's instructions to his negotiators were, 1, that there should be no longer any exclusive form of religion in France, and that therefore the only thing that could be done was merely to state that the Roman Catholic was the state religion, being that of the majority of the people; 2, that a new division of dioceses was requisite; 3, that with regard to the nomination and institution of the bishops, they might take the concordat of 1516 between Francis I. and Leo X. as a basis; 4, that all monastic orders requiring perpetual vows should remain suppressed. Above all he required the business to be promptly settled, and he wrote to Rome to that effect. The pope despatched to Paris Cardinal Consalvi, who smoothed down all difficulties, and the concordat was signed at Paris, the 15th of July, 1801, and was ratified by Pius at Rome, after some hesitation and consultation, on the 14th of August following. The principal scruples of the pope were concerning certain articles called 'organic,' which Bonaparte appended to the concordat, as if they had formed part of it, and which were proclaimed as laws of the state. (Botta, b. xxi.; Thibaudeau.)

From 1801 till 1804 Pius VII. enjoyed tranquillity at Rome, which he employed in restoring order to the finances, in ameliorating the judicial administration, in promoting the agriculture of the Campagna, and in other similar cares. His personal establishment was moderate, his table frugal, his habits simple, and his conduct exemplary. In May, 1804, Napoleon was proclaimed emperor, and some time after he wrote to the pope requesting him to crown him solemnly at Paris. After considerable hesitation Pius consented, and set off from Rome at the beginning of November of that year. The ceremony of the coronation took place in the cathedral of Notre Dame, after which the pope spent several months in Paris, visiting the public establishments, and receiving the homage of men of all parties, who were won by his unassuming yet dignified behaviour, and his unaffected piety. In May, 1805, he returned to Rome; and his troubles began soon after. In October, 1805, a body of French troops suddenly took military possession of Ancona. Pius remonstrated by a letter which he wrote to Napoleon, who was at that time at the head of his army in Austria. It was only after the peace of Presburg that he received an answer, in which Napoleon said, that he considered himself as the protector of the church against heretics and schismatics, like his predecessors from the time of Charlemagne, and that as such he had occupied Ancona to prevent it falling into the hands of the English or the Russians. Soon after, Napoleon officially required the pope, through his ambassador at Rome, to expel from his dominions all English, Russian, Swedish, and Sardinian subjects, and to forbid his ports to the vessels of those powers who were then at war with France. Pius replied at length in a letter to Napoleon, representing to him that his request was destructive of the independence of the Papal State and of its political neutrality, which were necessary to the welfare of the church and for the security of the numerous members of it who were living in those very countries with which the emperor was then at war. He said that the head of the church ought to be a minister of peace, and not to take part in a war which has not religion for its object; that if some of his predecessors had not always abided by this rule, he at least should not follow their example. Napoleon however insisted, and an angry correspondence was carried on between the two courts for about two years on this subject of contention, the neutrality of the Papal State being all the while merely nominal, as the French troops marching from and to Naples crossed and recrossed it at their pleasure, and the French also kept a garrison at Ancona, the only papal port of any importance. By degrees they extended their posts all along the Adriatic coast, and garrisoned the various ports. Some time after, a body of French troops, coming from Naples, passed through Rome, ostensibly to proceed to Leghorn, but they suddenly turned out of the main road and surprised in the night the town of Civitavecchia, of which they took military possession. In all these places they confiscated whatever English property they could find. The papal troops at Ancona, Civitavecchia, and other places, were ordered to place themselves under the direction of the French commanders, and some officers who refused to do so were arrested and kept in confinement. Napoleon in the mean time found fresh grounds of quarrel with the pope. He wished to declare the marriage of his brother Jerome with an American Protestant lady null; but Pius refused, saying that although the church abhorred marriages between Catholics and heretics, yet if they were contracted in Protestant countries, according to the laws of those countries, they were binding and indissoluble. ('Letter of Pius VII.' on this important subject, in Artaud, *Vie du Pape Pie VII.*, Paris, 1826.) He next accused the pope of dilatoriness in giving the canonical institution to the bishops elected to vacant sees in the kingdom of Italy. The delay was defended by the court of Rome on the ground of the non-execution or misinterpretation by the French of several articles of the concordat, especially as to the Venetian territories, which had been annexed to the Italian kingdom after the concordat was made, and which the pope did not therefore include in its provisions. Eugene Beauharnois, viceroy of the kingdom of Italy, wrote a very able and conciliatory letter to the pope, in order to bring about an arrangement, and the pope was induced to invite the bishops elect to Rome, in order to receive the canonical institution, when a threatening letter came, written by Napoleon from Dresden, after the peace of Tilsit, in the summer of 1807, in which he said that 'the pope must not take him for a Louis le Débonnaire; that his anathemas would never make his soldiers drop their muskets; that he, Napoleon, if provoked too far, could separate the greater part of Europe from the Roman church, and establish a more rational form of worship than that of which the pope was the head, that such a thing was easy in the actual state of people's minds,' &c.; and he forbade Eugene to correspond any longer with the pope, or send the bishops elect to Rome, for, he said, 'they would only imbibe there principles of sedition against their sovereign.' Matters were now brought to an open rupture. A French force under General Miollis entered Rome in February, 1808; took possession of the castle and the gates, leaving however the civil authorities undisturbed. The pope was prevailed upon to send Cardinal De Bayanne as his legate to Paris, to make a last effort at reconciliation, but the cardinal had not arrived at his destination when a decree of Napoleon, dated 2nd April, 1808, united the provinces of Ancona, Macerata, Fermo, and Urbino to the kingdom of Italy, stating in the preamble: 1, that the temporal sovereign of Rome had constantly refused to declare war against the English, and to enter into a confederation with the kings of Italy and of Naples for the defence of the peninsula; 2, that the interests of those two kingdoms required an uninterrupted communication between them; 3, that the donation made by Charlemagne to the see of Rome was intended for the advantage of the church, and not for that of heretics and enemies to that church; 4, lastly, that the ambassador of Rome at Paris had demanded his passport on the 30th March last, and the diplomatic relations between the two states were at an end.

Fresh remonstrances on the part of Pius were answered by threats of further hostile measures on the part of Napoleon, unless the pope entered into an offensive and defensive league with the kingdoms of Naples and Italy, and by a declaration that 'the pope would lose his temporal sovereignty and remain bishop of Rome as his predecessors were during the first eight centuries and under the reign of Charlemagne.' (*Note de M. de Champagny, Ministre des affaires étrangères, à S. Eminence le Cardinal Caprara*, 18th April, 1808.)

The war which began soon after in Spain prevented Napoleon from occupying himself with the affairs of Rome, which remained in a state of uncertainty amidst frequent clashing between the French military authorities and the papal civil officers. The papal treasury, impoverished as it was by the loss of its finest provinces, was obliged to pay the French troops which garrisoned the towns that still nominally belonged to the pope. All the disaffected and the turbulent, trusting to French protection, openly insulted the papal government. The pope remained confined to his palace on the Quirinal with his Swiss guard at the gates, not wishing to expose himself to violence by venturing out.

On the 17th May, 1809, Napoleon, who was then making war against Austria, issued a decree from Vienna, in which he united the remainder of the Roman states to the French empire, leaving to the pope his palaces and an income of two millions of francs (80,000*l.* sterling). The preamble of the decree was, as usual, grounded on the alleged donation of Charlemagne, 'his illustrious predecessor,' to the see of Rome, which donation, it was stated, was on the condition of feudal allegiance, Rome being still considered as belonging to the empire. 'But the union of the two powers, temporal and spiritual, having proved a source of perpetual discord, and of never-ending pretensions and assumptions, he, Napoleon, thought proper, for the security of his empire and of his people, to resume the grant of Charlemagne.'

On the 10th June, 1809, the pope issued a bull of excommunication against all the perpetrators and abettors of the invasion of Rome and of the territories of the Holy See. The bull was affixed to the gates of the principal churches of Rome and in other public places. The text of the bull is given by Cardinal Pacca, in his 'Memorie Storiche,' Appendix to the 1st part, No. v.

The French commander, Miollis, being afraid of an insurrection of the people of Rome, who had shown unequivocal signs of attachment to their sovereign, thought it expedient to remove Pius from the capital. It is stated, in the 'Memoirs of Las Cases,' that he did this without orders from Napoleon, who was still with his army in Austria, but that he concerted his measures with Murat, king of Naples, who sent him a reinforcement of Neapolitan troops for the purpose. General Radet of the gendarmerie was entrusted with the abduction of the pope, who had shut himself up in his palace on the Quirinal. Between two and three o'clock in the morning of the 6th of July, some men scaled the walls in the greatest silence, broke open several doors, and having opened the great gates, let in their comrades from without. The Swiss guards made no resistance, having orders to that effect from the pope. General Radet penetrated to the apartment in which Pius was, and found him in full dress, surrounded by several attendants. The general told him respectfully that he had orders to remove him from Rome unless he consented to sign an abdication of his temporal sovereignty, and on the pope saying that he could not do that, Radet told him that he must depart immediately. 'I then yield to force,' replied Pius; and, taking his breviary under his arm, he accompanied the general to the gate, where his carriage was ready, and drove off under an escort. He was taken first to Grenoble in Dauphiné, from whence he was removed, by order of Napoleon, to Savona in the Riviera of Genoa, where he remained till June, 1812, when he was removed to Fontainebleau, by an order from Napoleon. During his stay at Savona, Napoleon convoked a council at Paris of the bishops of his empire, but he found that assembly less docile than he expected, and he dissolved it without any conclusion being come to. The great question was how to fill up the vacant sees, when the pope refused the canonical institution. The pope at the same time would not recognise Napoleon's divorce from his first wife Josephine. In short, Napoleon found that unarmed priests were more difficult to conquer than the armies of one half of Europe. (Thibaudeau, *Le Consulat et l'Empire*, ch. 77; Botta, *Stòria d'Italia*, b. 25.) The plan of Napoleon was to have the pope settled at Avignon, or some other town of his empire, as his subject and his pensionary, and to have himself the nomination not only of the bishops, but of the cardinals also, by which means he would have added to his already overbearing temporal power the incalculable support of a spiritual authority which extends over a great part of the world. The resistance of Pius disappointed his views. 'Strange, but true,' exclaims Botta, 'in this instance the independence of the church was the only remaining prop of general liberty, and if the ecclesiastical authority had given way, no check was left against a universal and overwhelming tyranny.' Napoleon at last imagined that by removing Pius to Fontainebleau, he might succeed in overcoming his firmness. Pius was again obliged to make a long journey with the greatest secresy. He arrived at Fontainebleau in June, 1812, and was lodged in the imperial palace, and treated with marked respect. Napoleon had set out on his Russian expedition. After his return from that disastrous campaign, in December, 1812, he went to see the pope, embraced him, and treated him with studied attention; he also allowed several cardinals who were at Paris to repair to Fontainebleau, and at last, chiefly through their persuasions, he prevailed upon the pope to sign a new concordat, the 25th of January, 1813. It is not true, as some have stated, that Napoleon, in one of his conferences with Pius, had lifted his hand against him and struck him. Pacca ('Memorie Storiche,' part iii., ch. 1) denies this on the authority of Pius himself, but thinks it very probable that Napoleon spoke to his prisoner in an authoritative and threatening tone.

The principal articles of the concordat were, 1, that the pope should give to the bishops who might from time to time be elected to the vacant sees, in six months at latest after their nomination by the emperor, the canonical institution. If this were not granted after six months, the metropolitan of the province (and on his default, the senior bishop) should give the institution to the bishops elect, so that no see should remain vacant longer than a twelvemonth; 2, the pope should have the nomination to ten sees of France and Italy, besides that of the six bishops, called suburbicarii, in the neighbourhood of Rome; 3, the other bishops of the Papal State, who had been banished their dioceses for noncompliance with the orders of Napoleon, should not be reinstated, but appointed bishops 'in partibus;' 4, the pope was to fix his residence either in France or in the kingdom of Italy, and to hold his court and appoint his officers, ministers, and legates as before, in his quality of head of the church; 5, the emperor Napoleon granted full amnesty to the cardinals and other prelates or clergymen who had incurred his displeasure during the late controversy. (Pacca, *Memorie Storiche*, part ii., ch. 6.)

Napoleon hastened to publish the articles of the concordat, and to give them the force of laws of the empire; after which he granted free access to the pope to all cardinals and others who chose to repair to Fontainebleau. Pius, who had scruples concerning some of the articles which he had signed, laid them before the cardinals, and asked their opinion. Several of the cardinals, especially the Italian ones, such as Consalvi, Pacca, Litta, and Di Pietro, stated that some of the articles were contrary to the canon law and the legitimate jurisdiction of the Roman see, and pregnant with the most serious evils to the church, and they urged the necessity of a prompt retractation. They quoted the well-known example of Paschal II., who, in similar circumstances having ceded to the emperor Henry V. the right of investiture, hastened to submit his conduct to the judgment of a council assembled in the Lateran, and the council revoked the cession. [PASCHAL II.] Upon this Pius wrote to Napoleon, on the 24th of March, retracting his concessions, but proposing a new basis for a concordat; Napoleon however took no notice of the retractation, except by exiling some of the cardinals who, he thought, had influenced it. Napoleon soon after set off for his army in Germany, and the affair with the pope remained in suspense. It was only after the defeat of the French armies and their expulsion from Germany that Napoleon proposed to restore to the pope the Papal States south of the Apennines, if the pope would agree to a concordat. Pius answered, that he would not enter into any negotiations until he was restored to Rome. On the 22nd of January, 1814, an order came for the pope to leave Fontainebleau the following day. None of the cardinals were allowed to accompany him. He set off accompanied by an escort, and was taken to Italy. On arriving at the bridge on the river Nura, in the state of Parma, he met the advanced posts of the Neapolitan troops under Murat, who was then making common cause with the allied powers against Napoleon. Murat had taken military occupation of the Roman state, but he offered to give up Rome and the Campagna. Pius however preferred stopping at Cesena, his native town, until the political horizon was cleared up. After the abdication of Napoleon and the peace of Paris, Pius made his entrance into Rome, on the 24th of May, 1814, in the midst of rejoicings and acclamations. His faithful Consalvi soon after resumed his office of secretary of state. By the articles of the congress of Vienna the whole of the Papal States were restored, including the legations, which were not however evacuated by the Austrian troops until after the fall of Murat, in 1815.

The remaining years of the life of Pius were spent in comparative tranquillity, though not in idleness. He applied himself to adapt, as far as it was practicable, the civil institutions of his dominions to the great changes which had taken place in the social state. By a 'motu proprio' of the year 1816, he confirmed the suppression of all feudal imposts, privileges, monopolies, and jurisdictions; he abolished every kind of torture, including that called the 'corda,' or 'estrapade,' which was formerly a frequent mode of punishment at Rome; he diminished the land-tax; retained the register of hypothèques, or 'mortgages,' instituted by the French; laid down the basis of a new code of public administration, and in November of the following year he published a new code of civil procedure, in which he regulated the costs of judicial proceedings. He maintained the commercial courts established by the French, as well as the new system of police, enforced by a regular corps of carabineers, instead of the old 'sbirri,' who were ineffective and corrupt. (Tournon, *Etudes Statistiques sur Rome*, b. iv., ch. 6.) Unfortunately however the old system of secret proceedings in criminal matters was restored, as well as that of the ecclesiastical courts, which have jurisdiction also over laymen. Pius however made some important alterations in the form of proceeding of the Inquisition, abolishing torture as well as the punishment of death for offences concerning religion. He did probably all that he could do as a pope, and certainly more than any pope had done before him. Cardinal Consalvi took vigorous measures to extirpate the banditti of the Campagna; and in July, 1819, he ordered the town of Sonnino, a notorious nest of incorrigible robbers, to be razed to the ground. With regard to spiritual matters, Pius concluded a new concordat with France, Naples, Bavaria, and other states. He condemned by a bull the political society of Carbonari, as well as other secret societies.

In the month of July, 1823, Pius, who was then eighty-one years of age, had a fall in his apartments, and broke his thigh. This accident brought on inflammation, and after a few weeks he died, on the 20th of August, universally regretted. He was succeeded by Leo XII. Thorwaldsen was commissioned to make his monument, which has been placed in St. Peter's.

Pius VII. stands prominent among the long series of popes for his exemplary conduct under adversity, his truly Christian virtues, and his general benevolence and charity. Free from nepotism, modest, unassuming, and personally disinterested, he was a staunch though temperate defender of the rights of his see, and his meek bearing and unblemished character engaged on his side the sympathies of the whole Christian world, without distinction of community or sect, during his long struggle with his gigantic and ungenerous adversary.

PIUS VIII. (Cardinal Castiglioni) was elected in March, 1829, to succeed Leo XII., and died at the end of the following year. He was succeeded by Gregory XVI. Nothing remarkable occurred during his short pontificate. Pius VIII. died just before the explosion of the abortive attempt at insurrection in the Romagna, in consequence of the events of Paris, of July, 1830.

PIX, TRIAL OF THE. The private assay within the Mint, which sanctioned the delivery of the coins to the owner of the bullion, was not considered by our ancestors as a sufficient security for the integrity of the coins, but they required them to be submitted to a trial by a jury before the master could receive his discharge; and this trial was repeated at such short intervals as to form a sufficient check upon improper issues of the money. This final examination is technically called the Trial of the Pix, from the box in which the coins, which have been selected for that purpose, are contained. They are secured by three locks, the keys of which are respectively in the custody of the warden, master, and comptroller of the Mint.

The first regular public trial of the Pix upon record, according to Madox (*Hist. Excheq.*, vol. i., p. 291), took place in the ninth and tenth year of Edward I., when the king commanded, by writ, the barons of the exchequer to take with them Gregory de Rokesle, and straightway, before they retired from the exchequer, to open the boxes of the assay of London and Canterbury, and to make the assay in such manner as the king's council was wont to do, and to take an account thereof, so that they might be able to certify the king touching the same, whenever he should please.

From the form of this trial laid down in an indenture of the 18th Edward III., it was then to be made regularly every three months. In subsequent reigns however, down to a late period, this trial was made at uncertain times. In the reign of George II. it was called for when two or three millions had been coined. The practice of more modern times has been to call for a trial of the pix usually upon the appointment of a new master of the Mint, in order that the master who has retired may receive his discharge.

As the authority under which these trials were held occasionally varied, so did likewise the persons who sat as judges in the court. They were first the members of the king's council, then the barons of the exchequer, and again the members of the privy council as judges of the Star Chamber, where sometimes the king himself presided, as did James I. at an assay which was made upon the 9th of May, 1611. During the period of the interregnum, in which at least six trials of the pix were held, the authority and judges were in almost every instance varied. The court is now composed of such members of the privy council as are expressly summoned for that purpose, the lord-high-chancellor, or, in his absence, the chancellor of the exchequer, presiding.

Ruding was unable to discover any very antient ceremonial by which the forms of this trial were regulated. He found one however among the Harleian manuscripts in the British Museum (No. 698, fol. 169) which professed to be the order of older times. It was evidently derived from an earlier date, as in the form of the oath the standard is called the king's, and not the queen's, and was drawn up by Sir Richard Martyn, warden of the Mint, who held that office from the second to the thirty-seventh of Elizabeth. Ruding, in the appendix to his 'Annals of the Coinage of Britain,' has given an abstract of the pix verdicts from 1603 to 1802.

'The modern practice,' says Ruding, 'is for the master of the Mint to present a memorial praying for a trial of the pix. Upon this the chancellor of the exchequer moves his Majesty in council, who commands the trial to be holden; and the members of the privy council are accordingly summoned to meet at a certain day and hour (eleven o'clock in the forenoon) at the house lately inhabited by the usher within the receipt of his Majesty's exchequer at Westminster.* A precept is likewise directed by the lord-high-chancellor to the wardens of the Goldsmiths' Company, requiring them to nominate and set down the names of a competent number of sufficient and able freemen of their Company, skilful to judge of and to present the defaults of the coins, if any should be found, to be of the jury, to attend at the same time and place. This number is usually twenty-five, of which the assay-master of the Company is always one.

'When the court is formed, the clerk of the Goldsmiths' Company returns the precept, together with the list of names; the jury is called over, and twelve persons are sworn.

'The president then gives his charge, which used formerly to be general, like the oath, to examine by fire, by water, by touch, or by weight, or by all or by some of them, in the most just manner, whether the monies were made according to the indenture and standard trial-pieces, and within the remedies; but in 1734 the lord-high-chancellor Talbot directed the jury to express precisely how much the money was within the remedies, and the practice which he thus enjoined is still continued. The other parts of the charge necessarily vary according to the ability of the president and his knowledge of the subject.

'When it is concluded, the pix is delivered to the jury, and the court is commonly adjourned to the house of the president, where the verdict is afterwards delivered in writing.

'The jury then retires to the court-room of the duchy of Lancaster, whither the pix is removed, together with the weights of the Exchequer and Mint, and where the scales which are used upon this occasion are suspended, the beam of which is so delicate that it will turn with six grains, when loaded with the whole of those weights, to the amount of 48lbs. 8ozs. in each scale.

'The jury being seated, the indenture, or the warrant under which the master has acted, is read. Then the pix is opened, and the money which had been taken out of each delivery and enclosed in a separate paper parcel, under the seals of the warden, master, and comptroller of the Mint, is given into the hands of the foreman, who reads aloud the indorsement, and compares it with the account which lies before him. He then delivers the parcel to one of the jury, who opens it, and examines whether its contents agree with the indorsement.

'From the minutes which I took at a trial of the pix in the year 1799, it appears that it then contained—

Guineas	7590
Half guineas	1085
Thirds of guineas, or pieces of seven shillings	1073,

making by tale 8914*l.* 13*s.* 6*d.*, being the pieces taken from ninety-three deliveries, from the 3rd of December, 1794, to the 27th of March, 1799, which deliveries amounted in weight to 146,220lbs.

'The silver coins in the pix were only one groat, one quarter-shilling, one half-groat, and one penny, making by tale ten pence. They were taken from one delivery of 94lbs. 8ozs. 10dwts., on the 16th of December, 1795.

'When all the parcels of gold were opened and found to be right, then the monies contained in them were mixed together in wooden bowls, and afterwards weighed in five parts.

	lbs.	ozs.	dwts.	grs.
'The first weighed . .	42	8	0	12
The second	42	8	0	12
The third	42	8	0	12
The fourth . . .	42	8	0	12
The fifth	20	1	6	0
	190	9	8	0

'By calculation at the rate of 46*l.* 14*s.* 6*d.* to the pound troy, which is the proportion required by the indenture, they ought to have weighed 190lbs. 9ozs. 9dwts. 15grs.; so that they were deficient one pennyweight fifteen grains. But the remedy on 190lbs. 9ozs. 9dwts. 15grs. is 1lb. 3ozs. 18dwts. 0gr.; they were therefore within the remedy by 1lb. 3ozs. 16dwts. 9grs.

'The jury then took from the said monies so mingled together thirty-four guineas, thirteen half-guineas, and twelve seven-shilling pieces, for the assay by fire. The above coins were all the different sorts contained in the pix. By tale they amounted to 46*l.* 14*s.* 6*d.*, and they were in weight exactly one pound, which is the quantity taken for that purpose, particular attention being paid that some of every sort of coin shall be selected.

'The indented standard trial pieces of gold and silver, of the dates specified in the indenture, were then produced by the proper officers, and a sufficient quantity cut off from each, and compared with the pound weight of gold coin, and the aforesaid several pieces of silver coin, by the usual methods of assay.

---

* This house was subsequently allotted to the office of deputy clerk of the pells in the Exchequer. It was inhabited by the usher in 1799, when Mr. Ruding took his Minutes. It has since been destroyed, with the other buildings of the Exchequer, to make way for the new Houses of Lords and Commons.

'When that operation was finished, the jury returned their verdict, that the gold coins were in weight and in alloy sufficient according to the terms of the indenture; as were also the silver coins in alloy; but the quantity of them was too small to allow their agreement in weight to be ascertained.'

The trial in 1799 was an assay of the coins minted during a period of somewhat more than four years. The 'Gentleman's Magazine' for 1815 (vol. lxxxv., pt. ii., p. 207) contains an account of the trial of the pix upon the monies coined from the 19th February, 1806, to the 28th September, 1814, of gold to the amount of 47,613lbs. weight, and of 209lbs. of silver, which had been coined into 2,224,717*l.* 8*s.* 6*d.* of gold, and 647*l.* 18*s.* of silver; the gold consisting of half-guineas and seven-shilling pieces, and the silver of fourpences, threepences, twopences, and pence. The total contained in the pix was—

	£.	s.	d.
Gold . .	1719	18	0
Silver . .	0	12	0
	1720	10	0

(Ruding's *Annals of the Coinage of Britain*, new edit., 1840, vol. i., p. 69-76.)

PIZARRO, FRANCISCO, the discoverer and conqueror of Peru, was the natural son of Gonzalo Pizarro, an officer who served with considerable distinction under the Great Captain in the Italian wars. Gomara relates that Francisco was born upon the steps of a church, and in his earliest days was suckled by a sow. Garcilaso denies this, but all agree that he was born at Truxillo, about the year 1480. His education was so completely neglected, that he never learned to read or write, and he was employed by his father in tending pigs; but getting tired of this occupation, he ran away to Seville with some of his companions, became a soldier, and shortly afterwards embarked to try his fortune in the New World. The first occasion on which he gained distinction was during the expedition of Ojeda to Tierra Firma, in 1510, by whom he was left as his lieutenant in the new conquest. He gained the confidence of Vasco Nuñez de Balboa, whom he accompanied in his expedition to Mexico. On these occasions Pizarro showed himself superior to all his companions in courage, enterprise, and powers of endurance, and he became the favourite leader of the soldiers, who never felt so much confidence as when they were under his orders. Pizarro had seen fourteen years of arduous service, and was still one of the least wealthy of the Spanish colonists, when he joined Hernando de Luque and Diego de Almagro in the project of extending the Spanish conquests along the southern coast. Pizarro and Almagro could only give their personal labour and experience, while the wealthy priest, their associate, advanced 20,000 ounces of gold towards defraying the expenses of the expedition. Pizarro sailed from Panama in November, 1524, with one small ship, eighty men, and four horses, to attempt the conquest of a great country; leaving Almagro to follow with reinforcements as soon as he could raise them. Pizarro shaped his course to the south-east, but having in ignorance selected that period of the year in which the winds and currents were opposed to him, his progress was very slow. He touched at several places in Tierra Firma, where he found a most uninviting country, the low grounds of which were covered with swamps, the higher with impenetrable forests, having few inhabitants, and those fierce and hostile. Fatigue, famine, and disease having wasted his little band, Pizarro was compelled to await the arrival of Almagro at Chicama, who at length joined him, having undergone equal hardships. With unbroken spirit they decided on their course of action. Pizarro remained at Chicama while Almagro returned for fresh forces, which Luque with difficulty persuaded Pedrarias, the governor of Panama, to furnish. With these reinforcements, in the year 1526, Pizarro advanced from Chicama to the south, and explored the coast of Quito. He entered the bay of Saint Matthew, where he found a fertile country, the inhabitants of which were clothed in garments of woollen and cotton, with ornaments of gold and silver. This country being too populous to attack, Almagro returned to Panama for further aid, and Pizarro retired to a neighbouring island. The new governor of Panama, Pedro de los Rios, not only would not permit any new levies to be made, but sent a vessel to bring away Pizarro and his band. Pizarro refused to obey this order, and drawing a line on the sand with his sword, desired those who chose to remain with him to cross to his side: thirteen alone of his hardy veterans had sufficient courage to do so, with whom, and the crew of a vessel subsequently sent to his aid from Panama, he prosecuted his examination of the coast of Peru. He landed at Tumbez, where there was a palace of the Incas, and he ranged for some time peaceably along the coast. The abundance of gold and silver used by the inhabitants not only for ornament, but for utensils of common use, filled Pizarro and his companions with wonder. He returned to Panama in 1528, having encountered, during his absence of three years, greater hardships and dangers than any other adventurer of the age. The governor was not moved by his accounts of the opulence of the newly-discovered country, and it was settled by the associates that Pizarro should proceed to Europe to obtain the sanction of the emperor. By his address he succeeded in gaining the attention of Charles V. and his ministers, and without bestowing a thought upon his associates, he obtained for himself the appointments of governor and captain-general, and adelantado over all the country to be discovered, with supreme authority, both civil and military, stipulating in return to equip a certain force, and remit one-fifth of all the treasure that he should acquire to the crown. Pizarro was so poor, that without the assistance of Cortez he could not have performed his part of the agreement, and at length he sailed from Spain with only half the number of men required, among whom were his three brothers. He returned to Panama in 1530, and having with difficulty effected a reconciliation with Almagro, who was indignant at his perfidy, he sailed in February, 1531, with 186 soldiers, of whom 36 were horsemen, leaving Almagro as before to follow with reinforcements. Pizarro first surprised the principal town of the province of Coaque, where he obtained a great booty, which enabled him to despatch two of his ships to Panama and Nicaragua with remittances, which soon procured him recruits. Proceeding southward he attacked, and, after a fierce resistance, took the island of Puno, in the bay of Guayaquil. At Tumbez he was forced to remain three months, in consequence of a violent distemper among his men. At the mouth of the river Piura he founded the first Spanish settlement, and called it S. Michael. Fortunately for Pizarro a civil war was at this period raging in Peru between the brothers Atahualpa and Huascar [Peru], and each party requested his assistance against the other: Pizarro seized the opportunity, and marched up the country to Caxamarca. Having posted his little band in a strong position, he visited Atahualpa, who was encamped near that city, where the sight of a profusion of the precious metals that he found inflamed his cupidity to such a degree, that he resolved upon a plan as daring as it was treacherous and dishonourable. At a given signal, when Atahualpa was returning Pizarro's visit, the Spaniards opened a fire upon the followers of the Inca, the suddenness and surprise of which completely stupified them, and as no resistance was attempted, Pizarro carried off the unfortunate Atahualpa a prisoner to his quarters, where he was confined in a room 22 feet long by 16 feet broad. Having soon discovered the insatiable avarice of the Spaniards, Atahualpa offered as his ransom to fill this room with gold as high as he could reach. The offer was eagerly accepted by Pizarro, without the smallest intention of performing his part of the agreement. Before the whole was collected, the soldiers became so much excited at the sight of such vast treasure, that it was found impossible to restrain their impatience, and after setting aside the fifth part for the crown, and a share for Almagro's party, 1,528,500 pesos, or ounces, were divided. Pizarro's share was 2350 marks of silver, and 57,220 ounces of gold. Having obtained all that he could from Atahualpa, his feelings were soon excited to hatred and a desire of revenge, on perceiving that he was an object of scorn and contempt to Atahualpa, who had discovered that Pizarro was ignorant of the arts that he most admired in the Spaniards, reading and writing. Pizarro accordingly caused him to be put to death in 1533. The government of Peru was now so far overthrown, and the country so torn by intestine convulsions, that no effectual opposition was offered to Pizarro, who marched upon and captured Cuzco, the plunder of which city exceeded in value the ransom of Atahualpa.

In 1534, Ferdinand Pizarro landed in Spain with the royal share of Atahualpa's ransom, when Francisco's authority was confirmed with new powers and privileges, and Almagro was appointed adelantado of a country to be conquered to the southward of Pizarro's government. The reconciliation between Almagro and Pizarro had never been sincere; their evil passions were however for the present suppressed, and Almagro marched to the conquest of Chile, while Pizarro busied himself with the internal government of Peru, in the arrangement and administration of which he showed considerable judgment. In January, 1535, he founded the city of Lima, to which he gave the name of Ciudad de los Reyes. In 1536 the Peruvians rose and endeavoured to throw off the Spanish yoke: they cut off several detachments, and completely blockaded Pizarro in Lima, and his brother in Cuzco. This brought Almagro from Chile, who, having defeated the Peruvians, attacked Cuzco, took prisoners Pizarro's brothers, and subsequently Alvarado also; but certain compunctions preventing him from attacking Pizarro immediately after, the viceroy was enabled to collect his forces and attack Almagro, whom he took prisoner, and soon afterwards tried and executed in 1538. Pizarro's partiality in entirely leaving out the followers of Almagro in the subsequent allotment of lands, completely alienated them, and they attached themselves to the young Almagro, who soon became the rallying point for all who were disaffected towards Pizarro. A conspiracy was formed against him, and on Sunday, June 26, 1541, the conspirators, sixteen in number, headed by Herrada, entered the governor's palace at mid-day, the hour of repose in hot climates, and succeeded in reaching the staircase before an alarm was given. Pizarro, with his half-brother Alcantara, and a knot of faithful friends, defended themselves to the last. They fell, one after another, till Pizarro remained alone. At length, exhausted by the long conflict, and unable to parry the numerous blows aimed at him, he received a thrust in the throat, and expired in the 62nd year of his age, full of strength and vigour.

Robertson says of Pizarro, 'With a temper of mind no less daring than the constitution of his body was robust, he was foremost in every danger, patient under the greatest hardships, and unsubdued by any fatigue. Though so illiterate that he could not even read, he was soon found to be formed for command. Every operation committed to his conduct proved successful, as, by a happy but rare conjunction, he united perseverance with ardour, and was as cautious in executing as he was bold in forming his plans. To the soldierly qualities of intrepid valour, indefatigable activity, insurmountable constancy in enduring the hardships of military service in the New World, he added the address, the craft, the dissimulation of the politician, with the art of concealing his own purposes, and sagacity to penetrate into those of other men.'

(*Vidas de Españoles Célebres*, par Don M. F. Quintana; Robertson's *Hist. of America.*)

PIZZIGHETTO'NE. [Cremona.]

PIZZO. [Calabria.]

PLACE, LA. [Laplace.]

PLACENTA (Conchology), Schumacher's name for the *Placuna* of authors.

PLACENTA, in Botany, is that part of a seed-vessel on which the ovules or seeds are placed. It is always of a soft cellular texture, and is commonly found occupying the margin of a carpel. It is however as often confined to a single point, as in nettles, and many other plants. Morphologists usually regard it as a mere cellular expansion of the margin or surface of a carpel; but there seems to be no means of reconciling with this view some kinds of parietal placentæ and all kinds of the free central. This had led to the opinion that some placentæ are merely an expansion of the axis of growth, round and over which the carpellary leaves are folded; and there can be no doubt that this is true of Primulaceæ, Lamiaceæ, Boraginaceæ, and Graminaceæ at least. The subject has however as yet been very imperfectly investigated, and will probably be found connected with systematical points of great value. (Lindley's *Introduction to Botany*, 3rd ed., p. 208.)

PLACENTA. [Fœtus.]

PLACENTIA. [Piacenza.]

PLACE'NTULA, Schumacher's name for a genus of microscopic *Foraminifera*.

PLA'CITUS PAPYRIENSIS, SEXTUS, sometimes called by mistake Sextus Platonicus, or Sextus Empiricus, the author of a work entitled 'De Medicamentis ex Animalibus.' His age is unknown, but he is supposed to have lived about the fourth century A.D.; by some persons he is called Papiensis; but all that is known of him is that he was a physician, as appears from various parts of his work (cap. 27, &c.). It is written in Latin, and consists of thirty-four short chapters, each of which treats of some animal that was considered to have certain medical properties in different parts of its body. It is of little or no value, as may easily be seen from the following specimens:—against a quartan fever he directs the heart of a hare to be hung round the arm or neck (cap. 2); in order to be delivered for ever from pain in the bowels, he recommends a very young puppy to be dressed and eaten (cap. 11); for persons affected with phthisis or a bad cough, he orders the saliva of a horse to be taken, mixed with wine or water: 'This,' says he, 'I have myself tried, but it is a matter of notoriety (*expertissimum est*) that the horse will die' (cap. 14).

The work has been frequently published both separately and in different collections. It was first published in 1538, Norimb., 4to.; in the same year, Basil., 8vo. It is inserted in the first volume of the 'Medicæ Artis Principes,' published by H. Stephens, Paris, 1567, in the collection edited by And. Rivinus, Lips., 1654, 8vo.; in the thirteenth volume of the old edition of Fabricius, 'Biblioth. Græca;' and in Ackermann's collection entitled 'Parabilium Medicamentorum Scriptores Antiqui,' Norimb. et Altorf., 1788, 8vo. There are two German translations, one by Henisch, Basel, 1582, 8vo.; and the other by May or Mayer, Magdeb., 1612, fol. It should be mentioned that Constantinus Afer, in his work entitled 'De Remediis ex Animalibus,' has borrowed very freely from this treatise, and indeed copied great part of it almost word for word.

PLACOBRANCHIA'TA, or PLACOBRA'NCHIDÆ, M. Rang's name for a family of mollusks, forming his fifth family of *Gasteropoda* (Cuv.), but placed by Cuvier among his *Nudibranchiata*. [Nudibranchiata, vol. xvi., p. 362.]

M. Rang (*Manuel*) observes that M. de Férussac had shown to him some mollusks which had been sent to M. de Férussac from the Mediterranean, and in which M. Rang at once recognised the genus *Actæon* of Oken, or *Elysia* of Risso. M. de Férussac pointed out to M. Rang that the *branchiæ* covered the back and upper surface of the lobes, under the form of a vascular net, and therefore M. Rang is of opinion that it should be added to his family of *Placobranchidæ*, which had previously contained but one genus, viz. *Placobranchus*.

PLACOBRANCHUS. [Nudibranchiata, vol. xvi., p. 362; Placobranchiata.]

PLACU'NA. [Oysters; Pectinidæ, vol. xvii., p. 363.]

PLACUNANO'MIA. [Pectinidæ, vol. xvii., p. 364.]

PLAGAL, a term in old ecclesiastical music, relating solely to the Canto-Fermo, or Plain-Song, or Plain-Chant, and signifying *collateral*. The Plain-Song was seldom allowed to exceed the compass of an octave, and never went beyond nine notes. When the octave was so divided that the fifth was above the fourth, the mode or key was said to be *Plagal*. [Authentic.]

PLAGIO'STOMA (Conchology). [Spondylidæ.] M. Duméril uses the term *Plagiostomes* to denote the *Sélaciens*, Cuvier's first family, including the Sharks (*Squalus*, Linn.) and the Rays (*Raia*, Linn.), of the *Chondroptérygiens à branchies fixes*.

PLAGUE. [Pestilence.]

PLAGU'SIA. [Grapsus, vol. xi., p. 362.] *Plagusia* is also Browne's name for a fish: 'The little brown Sole with a pointed tail.' (*Jamaica*, p. 445.)

PLAID, the antient garb of the Scots Highlanders; still worn by the 42nd, 72nd, 78th, 79th, 92nd, and 93rd Highland regiments.

The belted plaid consists of twelve yards of tartan, which are plaited, and bound round the waist by a leathern belt, the upper part being attached to the left shoulder.

In the regulations relative to the clothing and half mounting of the British infantry, it is directed that in a Highland corp serving in Europe, in North America, or at the Cape of Good Hope, each serjeant, corporal, drummer, and private man shall have six yards of plaid once in two years, and a purse every seven years. (James's *Military Dictionary*, 8vo., Lond., 1810.)

In the glossary to Jamieson's 'Popular Ballads,' 8vo., Edinb., 1806, Plaiding is interpreted 'blanketing.' The plaids of the shepherds, the author adds, in the pastoral counties in the south of Scotland are actually a finer sort of blankets; and so are the plaids worn by the wives and daughters of the peasants in many parts of the north-east of Scotland at this day.

PLAIN-CHANT. [PLAIN-SONG.]

PLAIN-SONG, or *Cantus Firmus* (Lat.), or *Canto Fermo* (Ital.), a name given by the Church of Rome to the ecclesiastical chant, which most probably was borrowed partly from the music of the Greeks and partly from that used by the Jews in the synagogue. The *Plain-Song* is an extremely simple melody, if melody it may be called; it admits but one measure, the duple, and only notes of equal value. It is rarely allowed to extend beyond the compass of an octave, and never exceeds nine notes; and the staff on which the notes are placed consists of but four lines. The clefs are those of C and F. To St. Ambrose, archbishop of Milan, the church is supposed to be indebted for the regular form of the Plain-Song, and to the pope St. Gregory, surnamed the Great, for having perfected and brought it into that state in which it still continues to be used in the orthodox Roman church.

PLAIN SAILING. [SAILING.]

PLAINS. All those parts of the dry land which cannot properly be called mountainous are plains, and such compose by far the greater part of the earth's surface. Thus, for instance, it has been estimated that in South America the plains are to the mountainous country as 4 to 1. We are not aware that a similar calculation has been made for the other parts of the world, nor are there perhaps materials sufficiently exact for the purpose.

The word plain has but an indefinite meaning of itself, and seems to be rightly understood only when used in opposition to the word mountains, or when conjoined to the name of some known place, in which case it means the country itself so designated, or the environs of some particular spot. Thus we speak of the cities of the plains, the valleys of the plains, the plains of Lombardy, the plains of Quito, &c.

It were a great error to imagine that by the word plain a perfectly horizontal surface is always understood. In its usual acceptation it means a greater or less extent of country, flat in its general level as compared with a mountainous country. The more perfectly even and horizontal the surface, the better does it deserve to be called a plain, such as the plains of Venezuela and of the lower Orinoco, Mesopotamia, &c. But the surface of the ground may be gently waving, as Salisbury plain, and the Ukraine; or more prominently undulated, as the plain round Paris; or it may be studded with hills, as the plains of the Cassiquiare; or it may be traversed by valleys more or less wide and deep, like that part of France which lies between the Loire and the Garonne; or intersected with deep ravines, as the central plains of Russia, without ceasing on such accounts to be a plain.

Plains have been divided into two classes, high and low; but a moment's reflection will show that such denominations can apply rigorously only to the two extremities of a scale of elevation, at the bottom of which would stand, for example, the delta of Egypt or the llanos of South America (which latter are raised only about 150 feet above the level of the ocean, and in some places even less), and at the top the plain of Antisana, 13,435 feet above the sea-level; whereas the greater number of plains are found at intermediate heights, as the following will show:—

	Feet above the Ocean.
The plains of Hungary	200 to 250
The extensive plains on the north of the old continent from the Schelde to the Yenisei	250 to 300
Plains of Moscow	460
Plains of Lombardy	500
Plains of Lithuania	600
Suabia	900
The plateau of Valdaï	1000
Auvergne	1100
Switzerland between the Alps and Jura	1400
Steppes of the Kirghis	1300 to 1600
Bavaria	1650
Plains of the two Castilles	1800 to 2100
Mysore	2300 to 2600
Table-land of Persia	3800 to 4200
&c.	

Though we generally regard those plains which are the least raised above the surface of the ocean as the lowest, it must not be forgotten that round the Caspian and Aral there are plains of many thousand square miles considerably depressed below the sea-level; as is also the case with the plain or valley of the Jordan.

The term *plateau* has often been given exclusively to elevated plains, but this also is incorrect, inasmuch as by a plateau is sometimes meant a great extent of country considerably raised above the rest of the land, and having its mountains, its plains, and its valleys, as is particularly exemplified in the minor plateau of Albania, and in the great plateau of Central Asia. The latter contains four great chains of mountains, the Altaï on the north, the Thian-Chan and the Huen-lun in the interior, and the Himalaya on the south, between which are the vast plains of Dzoungaria, of Tongout, and of Tibet, with their rivers, valleys, and lakes.

Table-land, properly so called, is an elevated plain rising abruptly from the general level of the country, and being, as it were, the broad and horizontal or gently undulating top of an immense mountain, as the Nilgherry district of India. Sometimes there are several such, set one upon the other, at least on one or two sides, when they are called platforms or terraces, as those on the eastern slope of the Cordillera of New Mexico.

Some writers regard the words plateau and table-land as merely the French and English names for the same sort of elevation. Humboldt is of opinion that these names should be confined to elevations producing a sensible diminution of temperature, and accordingly to such heights only as attain to 1800 or 2400 feet. Some again, as Balbi, give the name of plateau to all high and extensive mountain-tracts.

Generally speaking, the plains of Europe are of middling elevation, the extremes of high and low being principally found in Asia and America. Thus while the great plains of Central Asia, about Ladak, Tibet, and Katchi, and round Koukounoor and elsewhere, attain a height similar to those of Quito and Titicaca, or from 9000 to 12,000 feet, the great marshy plains of Siberia along the borders of the Frozen Ocean are very slightly raised above the sea level, as is also the case with the plains of Bengal at the mouths of the Ganges, the whole of Mesopotamia, the Tehama of Arabia, &c.

In South America, contrasting with the lofty plains of Quito, of Santa Fé de Bogota, &c., are the llanos and the plains of the Amazon; while in North America, the interminable prairies and the low swamps round New Orleans form a striking contrast with the Rocky Mountains and the elevated plains of Mexico.

Of Africa little is known, but there is reason to believe that if the plains of Lower Egypt and part of the Sahara are very low, there may be high plains in the mountainous regions.

Plains differ not only in their elevation, but in the horizontality of their surface and general slope, and in the nature of their soil; which circumstances, together with their geographical position, influence their climate and productions, and give to the most considerable among them a particular character and physiognomy. It may be remarked that the rocky and sandy plains belong almost exclusively to the hot and temperate regions of the old world. The plains of America are generally characterised by their gramineous covering or their vast forests; the Asiatic steppes by a twofold appearance, being in some parts studded with low saline plants, and in others, as in Southern Russia, Siberia, and Turkistan, covered with plants of the families of the Compositæ and Leguminosæ; while the greater part of the European plains are richly cultivated.

We say such are the general characteristics, for there are plains of similar character and physiognomy in very different and widely separated regions of the world. The high land of the Campos Parexis, for instance, in South America, is very similar in physiognomy to the desert of Gobi in Asia. The *Desiertos*, near Coquimbo, are of the same character as the Sahara. The *Puszta* of Hungary resemble the savannas of the New World; and the pampas of Cordova are not unlike some of the Siberian steppes.

Though, as we have said, plains constitute by far the greater portion of the earth's surface, and are very varied in their appearance, there are nevertheless some which are remarkable not only for their extent, but for the peculiarities which distinguish them; peculiarities derived, no doubt, in part from the circumstances attending their original formation, and which no subsequent causes have been able to obliterate. These remarkable plains are known under the names of deserts, landes and heaths, steppes savannas and prairies, llanos, pampas, and selvas (or forest plains) of the Marañon. Deserts having been already described under their particular head, we shall here give a brief account of the others.

Heaths and Landes of Europe.—From Paris to Moscow and Cazan on the one hand, and to Astrakan on the other, is one continued plain, comprising the lowlands of Northern France, the Netherlands, the North of Germany, the whole of Prussia, and the greater part of Poland and Russia, as far as the first terraces of the Ural. Besides which there are many minor plains, as those of Wallachia and Bulgaria, Hungary, Lombardy, &c. The antient civilization of Europe has covered the greater part of its plains with cultivation and rendered some of these lands the richest in the world (the plains of Lombardy); nevertheless there are some spots which seem to defy all human efforts to bring them into cultivation; such are those between the Lower Volga and the Ural, of which we shall speak more fully in describing the steppes, and such are the heaths and landes. Of these, next to those of Russia, the most extensive are in Lapland and West Gothland. But the chief landes and heaths, properly so called, lie in the northwest of Germany. In Lower Silesia, Lusatia, and Brandenburg, there is little else than sand, and also in Pomerania and Mecklenburg, studded with a few hills, numerous lakes, and, along the maritime parts of the latter, having some woods of oak. In Hanover the gentle acclivities are covered with heath, which extends through part of Holstein to the centre of Jutland. The most sterile parts of Hanover however are the landes of Lüneburg and Verden between the Elbe and the Weser, and those of Meppen on the right bank of the Ems. Those of Lüneburg and its vicinity are said to cover a space of about 6000 square miles. These landes are covered with heath, with pine woods, and marshes. On the west of the Ems, about Bentheim, there are also extensive landes covered with swamps and stagnant pools. In the province of the Lower Rhine, in the environs of Monjoie, between Eupen and Malmedy, we again find vast landes coated with heath. In France, of which country about one-twelfth is unproductive soil, there are extensive landes and barren spots. That tract which extends eastward from the right bank of the Adour, and gives its name to the department, consists almost wholly of pools, marshes, and heath, and this sterile plain extends a great way into the department of the Gironde. The shingle plain of Crau, in the department of the Bouches du Rhone [BOUCHES DU RHONE], is well known, and likewise the sterile chalky plain of La Champagne Pouilleuse. In the kingdom of Naples there are considerable landes.

Steppes.—This name, which is Russian, is given more particularly to the extensive plains which lie on the northwest of Asia. Considered as a whole, the steppes have a character quite different from the other great plains of the world, though in different parts they present partially the distinguishing features which characterise the llanos, the savannas, the pampas, the sandy deserts, &c. Generally speaking, they consist of rich pastures intermingled with woods, barren sands, muriatiferous clay, and abounding in lakes, pools, and streams of salt and bitter waters.

From the sea of Azof on the west to the foot of the Little Altaï on the east, there is a band extending, in a north-east direction, from the mouth of the Kuban towards Torusk, where the undulations of the plain prevent the egress of the waters, which, percolating through a highly saline soil, are collected in the hollows into innumerable lakes and pools of salt water, which give a peculiar feature and interest to these steppes.

Further northward, the Siberian plains have a general slope towards the Frozen Ocean, and are intersected by the great rivers Obi, Yenisei, and Lena; between the lower courses of which extend immense frozen marshes, covered with moss, and interspersed with a few sandy and clayey hills crowned with tufts or clumps of stunted birch and other dwarf shrubs.

The greater part of what are properly called the steppes form a considerable part of the country known as Independent Tartary, which is inhabited by the nomadic hordes of the Kirghis Cossacks.

The steppe which lies on the north-west of the Caspian, bounded by the Caucasus, the sea of Azof, the lower course of the Don, and thence to the Ural or Iaïk, is inhabited by the Cossacks of the Black Sea and the Nogay Tartars. The whole of this steppe is characterised as composed of hills of a moving shelly sand, between which are beautiful green pastures, and marshy hollows with reeds and clumps of trees, among which are willows, poplars, and wild olive. There are numerous salt streams and brine pools, barren patches covered with a saline efflorescence, and in many places tufts of saline plants. The fertility of the hollows seems due to a sheet of water which, coming from the hilly range called Obstcheï Sirt, a branch of the Ural, flows immediately below the sandy surface, being probably retained by an impervious substratum.

Between the Iaïk on the west and a low ridge of hills on the east, which may be regarded as a south-eastern continuation of the Ural, and which extends between the Aral and the Caspian, is another steppe similar in character to that already described. It is occupied by the Kirghis of the little horde; while what is called the central or middle horde ranges over the vast steppe contained between the lake Aral and the Sir on the south, the low hills already mentioned on the west, the Ouloustaou and Naourgiuskaia ranges on the north, and the Sarasou on the east. With the exception of the Sir, all the waters of this great basin lose themselves in the sand, or in lakes more or less salt, the principal of which is the famous Aksakal Bari.

To the north of the last-mentioned steppe lies the great steppe or plain of Ischim, which extends from the eastern slope of the southern extremity of the Ural, across the Tobol, to the Irtish. It takes its name from the river Ischim, which, dividing it nearly in two, falls into the Irtish near Petropavloffskoï. The north-east part of this steppe towards Tara, on the left bank of the Irtish, is covered with dense forests abounding in game and rich in furs. Sables are in great number, but of indifferent quality; besides which there are bears, wolves, foxes, ermines and squirrels, beavers, lynxes, gluttons, and others, and still further north are reindeer. The Kirghis of the middle horde sometimes encamp in the plains of Ischim, of similar general character to those already described.

Crossing the Irtish, we enter the great steppe of Baraba, occupying all the space between that river and the Upper Obi. This steppe, lying nearer the foot of the mountainous district of the south and east, contains numerous lakes and pools, particularly in its southern portion. This district is in many places extremely fertile, and along the water-courses the grass grows luxuriantly. The north and north-west parts are wooded, but the more southern, those lying along the Irtish and towards the Altaï, have few trees, and are less fertile. The lake Tschany, the largest and nearly the most northerly of the great group of lakes, abounds in fish; the surrounding country is extremely fertile, and abounds in aquatic game, the chief nourishment of the Tartar tribes who live dispersed along the frontiers of this canton. Interspersed with the sandy, barren, and saline spots, are many places where there is excellent land for tillage, in which grain and flax succeed well. In those parts of this district which suit them there are great quantities of elks, roebucks, and wild boars. The Kirghis of the great horde occupy a more mountainous country to the south of the Sarasou.

Besides these great steppes, there are numerous other patches of greater or less extent and similar general character in Central Siberia, reaching from the Ural to the Lena.

Previous to the nominal subjection of the wandering hordes to Russia, that country had lines of fortified posts for its protection against these predatory bands; but now that the different hordes of Kirghis acknowledge the supremacy of Russia, and their several chiefs are paid by the Russian government, many of these posts have been abandoned, and open villages are now multiplying along the roads by which the Russian caravans travel towards Kiachta and in the direction of the mining districts of the Altaï. The inhabitants of these villages, some of which are very large, are the only stationary population of the steppes. The wandering tribes are very numerous, and are continually shifting their ground to find food for their numerous cattle, consisting of horses, camels, horned cattle, sheep, and goats. These herds, together with the booty taken in their incursions upon the Calmucks and others, form the sole wealth of the Kirghis, who lead easy and independent lives.

The extent of the steppes properly so called, excluding the marshy plains of the north, may be about 1,000,000 square miles.

Savannas or Prairies.—The central part of North America, from the Frozen Ocean to the Gulf of Mexico, may be regarded as one continuous plain, divided by a low watershed into the north-eastern basin, whose waters flow into the Polar Sea, Hudson's Bay, and, by the great lakes and St. Lawrence, into the Atlantic, and the basin of the Missouri and Mississippi, whose waters fall into the Gulf of Mexico.

This immense tract of country, estimated by Humboldt at 2,430,000 square miles, is extremely varied in climate, in character, and productions; for while the northern portion, which is watered by the Mackenzie, Back's River, the Churchill, and the Saskatchewan, is condemned for the greater part of the year to all the horrors of an iron-bound soil and stunted polar vegetation, palms and other tropical trees grow at the extremity of the southern portion. It is this southern basin, watered by the mighty Missouri and Mississippi, with their abundant affluents, that contains those extensive grass-covered tracts, the savannas and prairies. They lie chiefly on the western side of the Mississippi, though along the Illinois river they are found to the extent of 1,200,000 acres, and also in other parts of the basin east of the Mississippi. But the whole of the territory from the right bank of the Mississippi to the mountains is not one continued savanna, or even an unbroken horizontal plain; for it is rises towards the mountains, many of whose spurs are reached by the Missouri, which has erroded their extremities into bluffs. These ridges form the boundaries of the basins of the great tributary streams, the Platte, the Kanses, the Osage, the Arkansas, &c. Woods are also occasionally met with along the Mississippi and other watercourses, as likewise in Arkansas; and in some places, as between the Platte and the Missouri, there are extensive surfaces of moving sands resembling those of the African desert. Elsewhere again, as from the mouth of the Arkansas along the Mississippi, a distance of 450 miles long and 40 miles broad, the soil is all swamps and pools, with abundance of trees: this is also the case above Illinois lake and elsewhere. Along the upper Missouri, from the territory of the Mandans, is an interminable plain without trees or shrubs except in the marshy spots. In various parts, but more especially along the borders of the great plain, and in Arkansas, salt is found.

The savannas, or prairies, as they are also called, are divided by Flint, an American writer, into three kinds:—1, the heathy or bushy, which have springs and are covered with small shrubs, grape-vines, &c., very common in Indiana, Illinois, and Missouri; 2, dry or rolling, generally destitute of water and almost of all vegetation but grass; they are the most common and extensive: the traveller may wander for days in these vast and nearly level plains without wood or water, and see no object rising above the horizon; 3, the alluvial or wet prairies, the smallest division; they are covered with a rich vegetation of tall rank grass. The soil is deep, black, friable, and fertile, and abounding in pools without issue, left by the floodings of the rainy season. It is over the second kind chiefly that the bisons wander in herds of from 40,000 to 50,000. Stags, or more properly wapitis, are also very numerous; and between the Arkansas and Red rivers there are droves of wild horses. Deer are also numerous; and along the borders of the Missouri, above the Platte, or shallow river, the antelope abounds in herds of several hundreds. In summer wild goats are seen in vast numbers along the Mississippi. Above the Mandan villages are grizzly bears; and badgers, beavers, otters, foxes, wolves, racoons, opossums, squirrels, porcupines, and skunks inhabit the same region. To this enumeration of Warden's and Flint's, Lyell adds the jaguar. The waters teem with alligators and tortoises, and their surface is covered with millions of migratory water-fowl, which perform their annual voyage between the Canadian lakes and the shores of the Mexican Gulf.

Llanos.—The whole interior of South America, from the mountains of Caracas on the north to the Straits of Magalhaens on the south, is divided by comparatively low transverse ridges, running east and west into three great basins; that of the Orinoco on the north, that of the Amazon or Marañon in the centre, and that of the La Plata on the south. The first comprises the llanos, vast plains occupying a surface of 260,000 square miles. They may be divided into two principal portions: the first, beginning at the mouths of the Orinoco, extends westward as far as the Andes of New Granada, being bounded on the north by the Caracas, and on the south by the mountainous group of Parime and the Rio Apure, an affluent of the lower Orinoco. The other portion of the llanos, which is twice as extensive as the first, reaches from the Apure on the north to the Caqueta (an affluent of the Marañon) on the south; having the Andes on the west, and the sierra of Parime and the Orinoco on the east. The inclination of these plains is to the east and south, and they are traversed by many streams, which, taking their rise from the eastern slope of the Andes, bear their tributary waters to the Orinoco. As the medium height of the llanos does not exceed 200 feet, the course of the rivers is very slow and often scarcely perceptible.

The chief characteristic of the llanos, says Humboldt, is the absolute want of hills and inequalities, the perfect level of every part of the soil. Often in the space of 270 square miles there is not an eminence of a foot high. This resemblance to the surface of the sea strikes the imagination most powerfully where the plains are altogether destitute of palm-trees, and where the mountains of the shore and of the Orinoco are so distant that they cannot be seen. This unvarying equality of surface reigns without interruption from the mouths of the Orinoco to the Villa de Aurore and Ospinos, under a parallel of 540 miles in length, and from San Carlos to the Caqueta, on a meridian of 600 miles.

There are however, notwithstanding this uniformity of surface, two kinds of inequalities in the llanos. The first, called *brancos*, are horizontal banks of sandstone or limestone standing four or five feet higher than the rest of the plain, and sometimes many leagues in length. The second kind of inequality, called *mesa*, consists of convex eminences rising to the height of a few fathoms.

The llanos have different names in different parts: thus, from the Mouth of the Dragon, the llanos of Cumana, of Barcelona, and of Caracas or Venezuela, follow from east to west, when, turning southward from 8° N. lat., between the meridians of 67° 40′ and 70° 40′, we find the llanos of Varinas, Casuare, the Meta, Guaviaro, Caguan, and Caqueta. All these are again subdivided.

The aspect of the llanos is somewhat dissimilar in different places; but the greatest difference depends upon the seasons. The local dissimilarity arises chiefly from the nature of the palm-trees scattered about, which vary in different places, and also from the greater or less abundance and variety of the dicotyledonous plants which are intermixed with the grasses, the height of which latter is also very unequal, being sometimes only a few inches at a distance from the watercourses, and rising to a height of four feet in their vicinity. In this high grass the jaguar, or American tiger, lurks to spring upon the mules and horses that cross the plain. But the season of drought or of rain entirely changes the aspect of the greater part of the llanos. In the rainy season, says Humboldt, the llanos display a beautiful verdure, but in the time of great drought they assume the aspect of a desert. The grass is then reduced to powder, the earth cracks, the alligators and great serpents remain buried in the dried mud, till awakened from their long lethargy by the first showers of spring. These phenomena are observed on barren tracts of fifty or sixty leagues in length where the llanos are not traversed by rivers.

The principal and almost the only trees of the llanos are different varieties of palms. The *Corypha tectorum*, or Palma de Cobija, solitary or in clumps, rises here and there as a landmark through these trackless plains. It is chiefly found in the llanos of Caracas from Mesa de Peja, as far as Guayaval. Farther north and north-west, near Guavare and San Carlos, its place is taken by another species of the same genus. Other palm-trees appear to the south of Guayaval, especially the *Piritu*, with pinnate leaves, and the *Murichi*, whose beautiful verdure, at the period of the greatest drought, contrasts with the mournful aspect of the grey and dusty leaves of the cobija. Two or three other species of trees besides palms are also found in the llanos, and it is round these clumps that the llanos are the most fertile.

The great wealth of the llanos consists in the numerous herds which they feed. The first horned cattle were let loose in these extensive pastures by Christoval Rodriguez, about the year 1548, since which time they have increased to almost countless numbers. About 98,000 head of cattle are said to wander in the pastures round Calaboza. But, according to M. Depons, there are, from the mouths of the Orinoco to the lake of Maracaybo, 1,200,000 oxen, 180,000 horses, and 90,000 mules, the annual produce of which herds is estimated at about 5,000,000 francs. The richest proprietors are said to mark as many as 14,000 head every year, and sell to the number of five or six thousand. According to official documents, prior to the Revolution the exportation of hides from the whole capitania-general amounted annually, from the West India Islands alone, to 174,000 skins of oxen and 11,000 of goats; and as in this account no mention is made of fraudulent dealings in hides, it would appear that the number of 1,200,000, stated above, is much underrated.

All the parts of the llanos are not equally favourable for the breeding of mules and oxen; but in some of those places, where the herds are less numerous, the pastures are so fertile as to furnish meat of an excellent quality for provisioning the coast.

The horses of the llanos are not very large, but are descended from a fine Spanish breed. Deer are natives of these plains.

The greatest curiosity of the llanos are the gymnoti, or electrical eels, which live in the pools as well as in the rivers of this part of South America.

We may also mention, as distinguishing the llanos from the pampas, and from the plains of North America, the Sahara, and the steppes of Asia, the total absence of any formation of muriate of soda.

Pampas, from an Indian word, which, in the Quichua language, signifies properly a flat, is the name given to extensive plains in the southern and central parts of South America. Those which lie to the south and north-west of Buenos Ayres are called, the former the Pampas of Buenos Ayres, or simply the Pampas, and the latter the Pampas of Cordova. The plains to the south of the province of Chiquitos bear the name of the Pampas de Huanacos. There is also one more to the north, between the river Beni and the river Marmore, a tributary of the Madeira; and lastly, to the north between Huallaga and the Ucayal there is another, called the Pampas del Sacramento.

The Pampas of Buenos Ayres are bordered on the west by the forests which lie along the base of the Andes of Chile; on the east by the Atlantic; on the south by the Rio Negro and Patagonia, the interior of which, though little known, seems to be of the same nature with the pampa itself; and on the north-east by the Rio de la Plata. In the direction due north the pampa narrows between the Parana and a ridge coming from the Andes, called the Sierra de Cordova.

This region, reckoning to the foot of the mountains on the west, occupies a surface of about 315,000 square miles. This plain has no general slope, or rather it slopes so gently towards the east, that the slightest inequalities, together with the absorbing nature of the soil and the great evaporation, are sufficient to arrest the course of the waters; so that, with the exception of the rivers Colorado and Negro, which come from the Cordilleras, and which traverse the southern part of the pampas, and the Salado, a small stream which flows into the Rio de la Plata at its mouth, the pampas have no running waters, but, instead of them, a great many shallow pools, of which the water is often brackish. There is one at about four hundred and fifty miles from Buenos Ayres, in the direction west-south-west, always filled with salt, from which the city of Buenos Ayres was yearly supplied before the port was thrown open to foreigners. The southern part of the pampas is sandy, with patches of saline plants and stunted trees; the northern parts are covered with grass, supplying food to large herds of cattle and wild horses, the descendants of those first introduced by the Spaniards. It is said that several million head of cattle and about half as many horses feed on the Pampas of Buenos Ayres. There are also wild beasts.

This plain is traversed by a road which leads from Buenos Ayres to Chile, along which the traveller meets with huts, which form stations, distant from each other about seven or eight leagues. The journey may be made on horseback or in a carriage, but it is sometimes dangerous, on account of the Indians.

The Pampa of Cordova extends from the right bank of the lower Parana to the Sierra de Cordova at the west. On the north it joins the sandy plains or *travesia* of Santiago del Estero.

This pampa resembles that already described in all things, excepting being traversed by a greater number of streams All these streams however, with the exception of the Rio Salado, which falls into the Parana, lose themselves in the sands, or end in marshes and lakes without issue, and which in the country are called *Lagunas*. Such is particularly the case with the Rio Dulce, which, rising in a fertile valley on the eastern slope of one of the lateral chains of the Andes, passes by S. Miguel de Tucuman and Santiago, and finally empties itself into the Lagunas de las Porongos; the same is also the case with the Rio Primero, on which is situated Cordova, the best of all the towns of Tucuman, the residence of a bishop, and where the Jesuits had formerly a celebrated university.

Throughout the whole of the country between the Parana and the mountains to the west, from Chaco on the north to the extreme southern extremity of the Pampa of Buenos Ayres, says Azara, there is neither river, lake, nor well that is not brackish. Even the Pilcomayo and the Vermejo partake of this saltness; and the same author assures us that he has seen in lagunas, dried up by the heat, a layer of Epsom salts above three inches in thickness.

The inhabitants of the fertile valleys lying to the west and north of the plains of Tucuman, similar in some respects to Little Bucharia, rich in their flocks, without ambition, and without care, close the day in rural amusements worthy of being sung by Theocritus and Virgil. It is nevertheless true that there are spaces of many square leagues in extent condemned to absolute sterility. The traveller may pass for days together over sands and stones, between which there spring up here and there some saline plants, without meeting with any other objects than a few isolated huts on the borders of some brackish stream; these barren districts are generally designated by the term *travesia*.

Pampa of Huanacos.—Leaving the Pampa of Cordova on the south, and travelling through forests swarming with bees, which extend beyond the Rio Dulce and the Salado, we enter on the territory of the Abipones, a race of very warlike Indians; after which, crossing the Rio Vermejo, we gain the plains of the Gran Chaco, occupied by more or less savage indigenous tribes. This region is traversed by the Rio Pilcomayo, which, passing near the mines of Potosi, falls into the Paraguay below the city of Assumption. To the north lies the Pampa de Huanacos, adjoining the province of Chiquitos, bounded on the east by the great laguna of Xarayes, through which passes the frontier of Brazil; on the west by the heights of Santa Cruz de Sierra, and on the north by the forests of the province of Moxos and the sandy plateau called Campos Parexis.

Pampa de Moxos is on the north of the province of Moxos, between the rivers Beni and Marmoré; and between the junction of this latter and the Guapore, another source of the Madeira, are other pampas of considerable extent.

Pampa del Sacramento.—This pampa is situated on the north-west of Cuzco. It differs from the other pampas in having a more tropical vegetation, and in its soil not being saline. It occupies a surface of from 54,000 to 63,000 square miles.

Such are the principal pampas of South America; and, if we include a part of Patagonia as being of the same nature with the pampas, we shall have, without reckoning the pampas of Moxos and Sacramento, and a number of spots of similar character but less extent, an almost uninterrupted band, extending from the Campos Parexis, in latitude 15° S., to the bay of St. George in 45°, or about 2800 geographical miles long and 300 wide, or a surface of 840,000 square miles of plain, partly sand, and partly marshy and saline, and producing hardly anything but pasture and a few stunted trees. Humboldt estimates the whole of the pampas of Rio de la Plata and Patagonia at 135,200 square leagues of 20 to the degree.

The *Selvas*, or forest-covered plain of the Marañon.—Independent of the vast forests which cover great part of the plains of North America, particularly on the east of the Mississippi, there is the immense plain of the Marañon in South America, extending over a surface of 2,340,000 square miles, of which about 719,000 are covered with primeval forests, the rest of the space being occupied by the waters, and by open patches of a character similar to the llanos and savannas, though little known. We merely mention this region here as one of the most extensive continuous plains in the world.

If the great plains we have described owe their peculiar character to climate and situation, a very little reflection will suffice to show the immense influence which they in their turn must exercise over the climate of the regions contiguous to them, and the great modifications they must effect on mere astral temperature. Indeed the curves of the isothermal lines sufficiently prove that the several climates of the earth depend on the joint action of solar irradiation, and the magnitude, distribution, conformation, soil, and productions of the solid parts of the globe, and the extent and relative position of the great bodies of water by which they are surrounded. Nor have the vast plains of Asia and America performed a less important part in the moral history of mankind, whether as having favoured or opposed the emigrations of nations and the progress of civilization.

PLAN. This word (which is the same as Plane) means a representation of a plane section of any building, country, &c. Usually it is to the horizontal section that the term is applied, the words section or elevation being used to signify the vertical plans. A map is not properly a plan, but a Projection, unless the country represented be perfectly level: nevertheless the term is commonly applied to maps of very small portions of a country, as an estate or a town.

PLANA'RIA, Captain Brown's name for a genus of fossil shells which are discoïd, and much resemble *Planorbis;* but the outer lip is reflected; and the form is considered to have been marine. Mr. Lea notes a new species, *Planaria nitens*, from the Claiborne beds, Alabama. (*Contributions to Geology*.) *Planaria* had been used by Müller, Lamarck, and others, to designate a genus of animals placed by Cuvier among his *Intestinaux Parenchymateux*, but they do not live in other animals, and are only found in fresh or salt waters.

Dr. Johnston describes several British species of *Planaria*, all marine, in the 3rd and 4th vols. of the *Zoological Journal*.

PLANAXIS. [Entomostomata, vol. ix., p. 452.]

PLANE. [Straight Line and Plane.]

PLANE, INCLINED. [Inclined Plane.]

PLANE. Botanists enumerate several species of this tree, of which two only deserve notice here.

The *Oriental Plane*, or *Chinar*, is a native of Asia Minor and the Levant, and, according to Royle, it stretches eastward as far as Cashmere. Its favourite spots are low situations, where the soil is rich and humid; as it ascends the sides of mountains it soon becomes scrubby, and degenerates into a bush. In favourable situations it becomes one of the most noble of all trees, with deeply divided leaves, glossy and bright green, and huge branches which spread in all directions from its massive trunk, forming in eastern countries the most agreeable of all shade. It appears to acquire a very great age, was extensively employed by both the Greeks and Romans for avenues and other purposes of ornament, and is to the present day the handsomest of all the hardy deciduous trees in cultivation. It is also perfectly suited to the climate of England, suffering nothing from our winters or inclement and variable springs. Nevertheless by some strange inadvertence it is rarely seen with us in comparison with the next species, which is in all respects inferior. Its timber is fine grained, hard, and well suited to such kinds of joiners' work as do not require strength, for which its brittleness renders it ill suited. When the wood is very old it is said to acquire dark veins, and to assume the appearance of walnut.

The *Occidental Plane* is also a tree of very large size and of considerable beauty, although inferior to the Oriental. It is found over a great part of the North American Union, extending even into Canada, but its favourite range is in the moist rich grounds of the banks of the Ohio and in the Southern states, whence it straggles into Mexico. Its leaves are angular rather than fingered, by which it is readily known. In the United States it is called Buttonwood, and sometimes the Cotton-tree. A tree of this species is asserted to have existed on a small island in the Ohio, which, at five feet from the ground, measured forty feet four inches in circumference. This is the species found in Hyde Park, and in other public places near London, and is that usually planted in England, to the climate of which it is however ill suited. The wood is seldom well ripened, and is therefore liable to injury in winter, and it is continually damaged by our spring frosts; the consequence of which is that the trees grow slowly, and have always a shabby appearance, few of their leaves being free from brown and dead portions, unless in very favourable seasons. The multiplication of it ought therefore to be stopped, and that of the Oriental Plane substituted, if our planters have any regard to the beauty of the effect produced by their operations. A more unsuitable plant for the London parks than the Occidental Plane could hardly be selected.

Both species have the singular property of throwing off their old bark in hard plates of irregular size and form.

PLANE. [Mississippi, River.]

PLANET (ἀστὴρ πλανήτης, a wandering star), **PLANETARY THEORY, MOTIONS, PERTURBATIONS, INEQUALITY, &c.** The term planet was first used as one of distinction between the stars which preserve their places, or seem to do so, and those which have a sensible motion, and, as is now known, about the sun. The etymology would oblige us to include comets—many of the stars, which have small motions of their own, or proper motions, as they are called—all those double stars which revolve about each other—and all the satellites which revolve about other planets. As discovery proceeds, it is likely that every body in the universe will be found to be planetary. The word however has changed its meaning, and is used to stand for a heavenly body which makes successive revolutions about our sun. It thus includes—the old planets, Mercury, Venus, Mars, Jupiter, Saturn (excluding the sun and the moon, the most easily discovered planets of all)—the planet of Copernicus and Galileo, on which we live—the new planets, Vesta, Juno, Ceres, Pallas, and Uranus;—three comets certainly, those of Halley, Encke, and Biela, and probably many others.

The plan of this work leaves us little to say under so general a term as Planet, and that little consists mostly of references, and explanations of isolated points. The order of discoveries connected with the subject, so far as it is matter of history, must be looked for under Astronomy. It is impossible to separate the history of one part of astronomy from that of another: the fixed stars, on which all celestial measurements depend, must accompany the planets in every account of the latter; the mathematical and physical considerations which give rise to our power of predicting the motions and places of the planets, apply equally to those of the moon and comets.

By a Planetary Theory was once meant any hypothesis which serves to explain the motions of a planet, as actually perceived. Thus there was one theory of Mercury, another of Venus, &c., each (without connection with the rest) expounding the nature and magnitude of all the suppositions which must be superadded to that of the simple circular motion round the sun, in order to enable the theorist to predict the planet's place at any given future time. At present, by the theory of a planet is meant the deduction of its motion from the theory of gravitation. Given the places of all the bodies of the solar system at any one moment, together with their velocities and the directions of their motions, the assumptions of the theory of gravitation are found sufficient to deduce tables which almost rival observation itself in the accuracy with which predictions can be made; for an instance, see Moon. When tables are constructed with such fundamental data only, they are called *theoretical:* but if some of those details which should have been deduced from the theory of gravitation have been deduced from observation, the tables are then partly *empirical*. For the treatment of the theory of gravitation as a question of physics, see Attraction: for the deduction of the character of the main inequalities of the planetary motions, and most points connected with the detailed results of that theory, see Gravitation: for the results which are particularly connected with the secular inequalities, and the reasons which we have to infer the permanence of the whole system, unless acted on by some new and external cause, see Solar System. See also the general considerations under the word Theory.

The Planetary Theory, it must be remembered, in the sense in which those words are now understood, explains only the motions of the planets round the sun. A spectator situated on the last-named body would find it sufficient to predict the place among the stars, of every planet at every time: or a terrestrial astronomer might assign by it the places of the planets as seen from the sun, which are called *heliocentric* places. But our own circumstances, as being ourselves revolving about the sun, cause the apparent planetary motions to vary most materially from the real ones, and the *geocentric* places (or places as seen from the earth) to differ literally *toto cœlo* from the heliocentric places. Thus, as seen from the sun, a planet moves from west to east, always: as seen from the earth, it sometimes moves from east to west. As to this point, the circumstances of our day are, in regard to the astronomical education of the world at large, a complete reversal of those which preceded the time of Newton. Formerly, the apparent motions were well known to those who knew anything; the real motions were matter of dispute: now, every well educated boy of fourteen has a very good notion of the real motions, while few, except astronomers, could distinctly explain the apparent ones, and maps of them are quite out of date. To explain these motions here would require us to introduce the contents of another article; the whole of what is necessary on this point will be found in TROCHOIDAL CURVES, the preliminary considerations being found under MOTION.

The places of the principal planets are usually given in the almanacs, at intervals of several days, in a manner which is sufficient to find them in the heavens. In the 'Nautical Almanac' is now to be found a Greenwich meridian ephemeris of every planet for every day in the year, in which the places are predicted to the smallest quantities, so that the reduced observation of any one day affords an immediate comparison of the theoretical tables with the fact.

PLANETA'RIUM. [ORRERY.]

PLANIPENNES, one of the sections of insects into which Latreille divides the order Neuroptera. The species of this section have the antennæ composed of numerous joints, always larger than the head; the mandibles are well developed, and the posterior wings are nearly equal in size to the superior; they are either naturally extended or have the anterior portion simply folded beneath: the reticulations of the wings are very distinct, and they are naked; the maxillary palpi are usually filiform, or slightly thickened at the apex, shorter than the head, and four-jointed.

This section is divided into four families:—

1st. The *Panorpidæ*, the species of which are distinguished by all the tarsi being five-jointed, and the anterior portion of the head drawn out in the form of a snout or proboscis.

It consists chiefly of the Linnæan genus *Panorpa*, which is now divided into the following genera:—*Nemoptera*, Latreille; *Bittacus*, Lat.; *Panorpa proper*, and *Boreus*, Lat.

The *Panorpa communis* of Linnæus is a common insect in hedges and in woods. It is about three-quarters of an inch in length, black; the snout and apical portion of the abdomen red; the elytra are irregularly spotted with black.

Of the genus *Boreus* we also have an example in this country; the *B. hyemalis*, a small insect, which is found usually in moss, and during the winter time.

2ndly. The *Myrmeleonidæ*. In this family the antennæ are more or less suddenly incrassated at the apex; the head is transverse, and the eyes project considerably; there are six palpi, of which the labial are usually the longest and thickened at the apex; the first segment of the thorax is small; the anterior and posterior wings are equal, elongated, and, when closed, meet at an angle like the roof of a house; the abdomen is usually elongated, and furnished at the apex in the male sex with two appendages; the legs are short. These insects are found in the warmer portions both of the Old and New World: they form two genera according to Fabricius, *Myrmeleon* and *Ascalaphus*. The curious habits of the larva of the *Myrmeleon Formicarium*, a European insect, though not found in this country, have often attracted the attention of the naturalist. This insect is of a greyish colour, and short and broad form; the head is small, and furnished with a large pair of sharply pointed mandibles, which serve both to seize its prey and to extract the juices upon which it lives. The number of ants destroyed by this larva has obtained for it the name of Ant-lion. Although provided with six feet, says Latreille, it moves very slowly and almost always backwards. Thus, not being able to seize its prey by the celerity of its motions, it has recourse to stratagem, and lays a trap for it in the form of a funnel-shaped cavity which it excavates in the ground, at the foot of a tree, old walls, or in a bank exposed to the south. Having completed this cavity, it hides itself at the base, in the mould or sand, and waits until some insect is precipitated into it; if the insect endeavour to escape, or be at too great a distance for it to seize, the Ant-lion showers a quantity of sand upon the victim by means of its head and mandibles, and thus succeeds in overwhelming it and bringing it within reach of its mandibles. Having sucked the juices from the carcass, the remains are thrown at a distance from the domicile. When about to pass into the pupa state, the Ant-lion encloses itself in a white silken cocoon, mixing grains of sand with the outer surface. The perfect insect is about one inch in length; blackish, spotted with yellow; the wings are transparent, and have black nervures spotted with white; some dusky spots and one whitish spot are observable near their extremity.

The third family consists of the *Hemerobiidæ*, which are chiefly distinguished from the last group by their filiform antennæ; they moreover differ in having only four palpi In some (the genus *Hemerobius*), the wings when closed meet at an angle, as in the Myrmeleons, whilst in others (*Sembles*) they are horizontal.

Hemerobius perla is common in our gardens, and is often seen flying about the lilacs, especially towards the evening. It is rather more than half an inch in length, of a green colour, and has transparent wings with numerous green nervures; its eyes resemble small globes of gold; when touched, it emits a very disagreeable odour.

To the fourth family Latreille applies the name *Termitinæ;* it includes those Neuropterous insects which have a semi-complete metamorphosis; they are terrestrial and active, and are either carnivorous or gnawers in all their states.

The *Mantispæ*, which Latreille places in this division, differ much from other insects of the order in having large anterior legs formed like those of the Mantidæ; their tarsi have never more than four joints; the mandibles are strong, and the wings have no folds; the inferior pair are either smaller or equal to the superior wings in size.

Besides the genus *Mantispa*, this family includes *Raphidia*, *Termes*, and *Psocus*.

The last family of the *Planipennes* is the *Perlidæ*, in which the tarsi are three-jointed, and the mandibles almost always small and partly membranous; the inferior wings are wider than the others, and are folded when not in use. This family contains the genera *Perla* and *Neumora*. The larvæ of the Perlæ live in the water, and inhabit sheaths which they construct by joining together various substances by means of a silken web which they spin.

PLANISPHERE. This term originally stood for any representation of all or part of the sphere on a plane; it is now out of use, at least in that sense. It has partially however been retained (and it would be desirable that this meaning should become fixed and general) to signify any contrivance in which plane surfaces moving on one another fulfil any of the uses of a celestial globe.

The instrument* which we proceed to describe is one which, at or near a given latitude, is, for ordinary uses, that is, for finding the position of the heavens at any one moment, much more easily used than the celestial globe, and very much less expensive. A circular disk of pasteboard, on which the stars visible in our latitude are laid down, turns on a second disk, round which are the days of the year on one circle, and the hours of the day on another. A third and hollow disk turns upon the same pivot, the hollow part being so cut that the portion of the heavens which it shows is precisely that which is visible at one time in the latitude of the instrument: the points of the compass are marked round the rim of the hollow disk, or of the horizon. The effect is, that by setting the disk which contains the stars to the day of the year, and the hollow disk to the hour of the day, the part of the heavens visible at that day and hour is distinctly shown. The time at which any star rises, culminates, and sets can be immediately found within a minute. We strongly recommend this instrument to those who study the face of the heavens, as being much superior to the globe.

PLANORBIS. [LIMNEANS, vol. xiii., p. 498.]

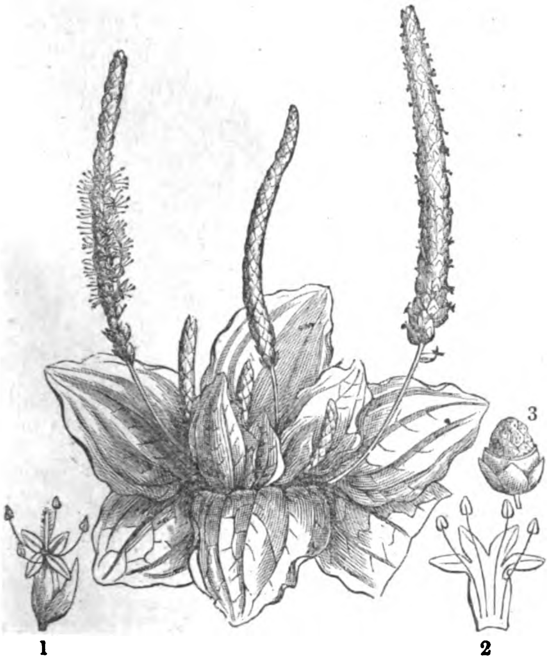
PLANORBULI'NA, M. D'Orbigny's name for a genus of microscopic *Foraminifera*. [FORAMINIFERA, vol. x., p. 348.]

---

* These planispheres are very well manufactured by Messrs. Smith and Sons, 172, Strand. We mention this, because some which we have seen are very erroneous: we remember one in which the equator cuts the horizon a great way from the east and west points.

PLANTAGENET. [HENRY I., II.]

PLANTAGINA'CEÆ are a small natural order of plants belonging to the monopetalous exogenous series, principally characterised by having a superior one-celled simple ovary, terminated by a simple linear stigma, many seeds, with a minute embryo in the midst of much albumen, and stamens with extremely weak filaments. They consist of herbaceous or suffrutescent plants, of which the *common Ribgrass*, or *Plantago lanceolata*, may be taken as the type, and are of no material importance to man. The mucilage surrounding the seeds of some is occasionally used in the stiffening of muslins by the manufacturers, and the *P. lanceolata* is sown on sandy bad lands as a material for sheep food. In structure Plantago possesses the rare peculiarity of having the cavity of its simple carpel divided into two by a vertical additional plate.



Plantago major.

1, a flower: 2, a corolla cut open; 3, a seed-vessel, with the upper half of the pyxis removed.

PLANTI'GRADA. [CARNIVORA, vol. vi., p. 307.] The genera placed by Cuvier in this tribe are *Ursus* [BEAR], *Procyon* (Racoons), *Ailurus* [PANDA], the *Benturongs* (*Ictides*, Valenc.), the *Coatis* (*Nasua*, Storr). (Here, he thinks, can hardly be placed the *Kinkajous*, or *Pottos*, Cuv. (*Cercoleptes*, Ill.), which join to plantigrade motion a long and prehensile tail, like that of the *Sapajous*, a short muzzle, a slender and extensible tongue, two pointed molar teeth in front, and three tubercular molars backwards.) *Meles*, Storr [BADGER; MELES], *Gulo*, Storr [GULO], and the *Ratels* (*Viverra mellivora*, Sparm.; *Viv. Capensis*, Schreb.), which have one false molar less in each jaw than the *Grisons*, and their tubercular molar above but little developed, so that they approach the *Cats* in their teeth, whilst their external form is that of the *Grison* and the Badger; the legs being low, and the feet plantigrade, with five toes on each foot, armed with very strong claws, &c. (*Règne Animal.*)

PLANTING and PLANTATIONS. Planting is the operation of placing in the soil the roots of a plant which has been previously removed; and the preservation of the roots is the first thing to be attended to. It should be kept in mind that the *spongioles*, or delicate extremities of the fibres, are the parts by which the chief supply of food from the earth is absorbed by the plant. Their tissue being tender and almost naked, they are very susceptible of injuries from mechanical action; and being adapted for performing their functions in a humid medium, they readily suffer from being kept for any length of time exposed to free air and drought. In taking up the plants therefore, the roots should be loosened in such a manner as to receive the least possible violence in the operation. Plants in pots can be shifted from one place to another without exhibiting symptoms of deranged functions; and if it were possible to preserve the spongioles of a large tree as entire as those of a plant in a pot, the same successful result would follow. But as it is next to impossible to do this, we can only attempt to preserve them as far as circumstances will permit. If the tree be large, a trench should be opened beyond the extremities of the roots, of sufficient width and depth to allow the process of undermining to be freely carried on. The roots should be gradually set at liberty by a round-pronged fork, the prongs tapering so as to be easily inserted, yet not by any means so sharp as to prick the roots. As the fork is being used, the soil from among the roots will fall into the open trench, but as it accumulates there it must be cleared away, and at the same time the portion of roots set at liberty will require to be slightly tied together with pieces of matting, and, if necessary, supported by temporary stakes, or held to one side by an assistant, whilst the planter proceeds in liberating others. If there be, as is frequently the case, a tap-root extending to a much greater depth than the other roots, and if the latter have been carefully preserved during the operation, the tap-root may be dispensed with, for it could only be raised in a mutilated state, owing to the great solidity of the earth at such a depth.

Although it is very desirable to preserve the greatest possible quantity of sound roots, yet all that are bruised or lacerated should be cleanly amputated up to the sound parts. Cross-roots are apt to gall the others when they become large, and therefore the sooner they are removed the better. When the plants are young and in the course of being occasionally removed in a nursing state, all irregularities in the roots should be corrected, which can then be done with comparatively little injury, as the roots of young plants bear a greater proportion to the top than seems to be the case at a more advanced period of growth, and the loss of any of them is consequently felt less. In the early stage of rearing trees, while the proportion of roots predominates, it may be found advisable in various cases to shorten not only the tap-root, as above mentioned, but also judiciously some of the other strong roots, in order that subdivisions of a more fibrous nature may be produced, and a number of rootlets substituted for large root-branches. Even in the case of large trees this principle has been acted upon for centuries, and latterly it has been strongly advocated and put in practice for the purpose of producing immediate effect in park or landscape scenery. A trench is cut out round the tree, and the roots shortened wherever they happen to traverse this trench, so as to leave it quite clear. This being done, the trench is filled up, either with its own excavated soil, or, in very particular cases, with fresh soil. The tree has still a sufficient number of undisturbed roots to keep it alive; and in fact it ought not to be merely kept alive, but as many roots should be left as will ensure its continuing in a healthy though not a vigorous state of growth. In the course of a year or two after this operation has been performed, a number of young roots will have been protruded from the various amputations into the loosened soil of the trench; and partly from the possibility of preserving these roots, and partly from the top becoming habituated to a more limited supply of food, the tree feels comparatively little the change consequent on transplantation.

Roots may be produced of a proper description for planting by the adoption of such means as the above, and if care be taken, they will suffer little from the operation of removal. Still they may be seriously injured from exposure to air, and more especially to drying winds, frost, and even to wet. To be covered in the soil is the natural condition of the roots of most vegetable productions, and therefore endeavours should be made to place them in such a condition with the least possible delay; or at all events, if circumstances render delay unavoidable, such means should be adopted as will preserve them in a state of moisture similar to that which they have in the soil. It is however necessary to observe, that when the tops are closely packed up and evaporation from them prevented, the roots should be kept rather dry than otherwise, for under such circumstances damp is found to be much more frequently destructive than a little dryness.

Though the preparatory steps to planting, as regards roots and their preservation, may be properly taken, yet, if the operation be not performed at the proper season, success will, not be complete. It is true that instances may be adduced of planting being done at the very opposite season to that which is here recommended as the best; but such cases are only examples of what may be done by extraordinary care in adopting artificial means so as to imitate more natural circumstances. It is a well known fact that plants are subject to a process of evaporation from all the parts which are exposed to the atmosphere, provided the latter is not in a state of saturation. The source from whence this evaporation is supplied is the moisture of the soil, and the roots are the media by which it is collected and transmitted to the stem, branches, and leaves. If the expenditure be greater than the supply of moisture, the plant will begin to suffer; if the disparity be great and continued, a degree of desiccation will be occasioned sufficient to deprive the vegetable tissue of that moisture which constitutes the medium of intercommunication between the different cells; organization is destroyed; the chain which connected it with vitality is broken, and incapable of being reunited by any mechanical means.

A much greater amount of evaporation takes place from a given surface in some species than in others; but the amount as regards plants of the same species, all other circumstances being the same, is in proportion to the extent of surface which the respective individuals possess. The leaves of a lime-tree may have a surface equal to thirty times that of the stem, branches, and twigs which produce them, and consequently the demand on the roots for the supply of evaporation will be thirty times greater when in leaf than when the branches are naked. Instances might be adduced in which this difference would even be exceeded; but if, on the contrary, it were found considerably less, still there would be sufficient evidence of the impropriety of moving plants when in leaf: and it may be here remarked, that young leaves admit of the fluids being more rapidly evaporated than old ones.

The month of December is that in which the condition of the air with regard to moisture approaches nearest to that of complete saturation, and next in this respect is January, which is also the coldest. It might therefore be concluded that these months are the best for planting, more especially as they are the most opposite in character to June and July, which, from their being the hottest and driest, are found to be the worst. But November is also moist; and although the temperature of the season has not then reached its minimum, yet the foliage, accustomed to exercise its functions under a summer heat, can no longer perform them under a reduction of temperature, which, though not the lowest, is comparatively low as regards summer productions. The leaves in consequence lose their connection with the roots; the earth still retains considerable warmth; and although the absence of leaves in deciduous trees, and perhaps the inactivity of those of evergreens, may prevent the formation of wood, except in the most limited degree, yet the buds, whilst they are themselves increased in volume, maintain a corresponding action in the roots, sufficient in many instances to form fresh spongioles before winter, a process which is favoured by the soil being warmer than the atmosphere. Should circumstances occur to prevent the actual protrusion of cellular substance in the form of spongioles, still an accumulation of it will be taking place, ready to burst forth in spring. On this account therefore, although December, January, and February are sufficiently moist, yet *November*, or *as soon as the leaves have fallen*, is the preferable season for planting. There may be some exceptions, as in the case of very wet soils, where the plants, if not firmly rooted, are liable to be thrown out during winter, owing to which spring planting would be more proper. But under ordinary circumstances all deciduous trees will succeed best at the period above indicated. Such species as push forth their buds early ought certainly to be planted in autumn. Many of the Coniferous tribe will succeed well if planted soon after they have made their summer's growth: the earth is then warm, and the plants make roots very promptly. Some species of this interesting order of trees require to be planted either before winter, so as to have sufficient time to strike root, or *immediately* before their buds begin to burst in the spring. These species of trees are injuriously affected by exposure to dry cold winds, even when their roots are undisturbed by removal; but if planted at a season when several months must elapse before any perfect action can commence, the tops are apt to become dried up in the interval. It appears that if their juices become inspissated to a certain extent, they never again become liquified, probably owing to their resinous nature.

The watering of newly planted trees ought to be attended to. The supply in the first instance should be copious, in order to wash the earth into the cavities among the roots. Some err in keeping the roots of newly planted trees constantly soaked with water, as if they were those of bog-plants, for which only such treatment is proper. In watering, consideration should always be had to the nature of the plant, to which, if it delight in dry soils, no more water should be artificially applied than is necessary to moisten it as much as the soil in which the species grows naturally, and at a time when shoots and leaves are abundantly produced. When watering is performed, it should be done thoroughly, so as to reach the lowest portions of the root. In the case of plants being much dried from long carriage or other causes, the supply on first planting should be very moderate. The tops however should be frequently syringed, in order to moisten the bark and prevent its absorbing the organisable matter which descends towards the root by the inner bark. The flow must be extremely weak under such circumstances; but if it can be preserved from the effects of drought till it reach the extremities of the roots, the formation of fresh spongioles will immediately commence, and the tree may then be pronounced out of danger.

The manner of performing the operation of planting may be reduced to one general principle, that of placing the roots in the soil so as to imitate as closely as possible the position which they occupy when growing wild and uncontrolled. Plants indeed may be instanced whose roots have been observed in one situation penetrating to the depth of four or five feet; or in another, creeping along the surface, amongst stones, or into the crevices of rocks, with scarcely soil to cover them, as for example in the vine. But although roots can usually accommodate themselves to that position which the nature of the situation renders it alone possible for them to occupy, yet there can be no doubt that in all cases the extremities of the roots should be lower than where they diverge from the stem, a rule which, however self-evident it may be, is frequently violated in practice by making a basin-shaped hole, deepest in the middle, in which the roots are either doubled or have their extremities tending upwards on the sloping sides of the cavity.

The excavation for the reception of the roots of a plant should be considerably larger than those roots will traverse when extended at the time of planting. It should be as wide at bottom as at top. The bottom should be more or less convex, and the depth such as to admit of the roots being covered to the extent observed in undisturbed seedling plants of the same species; that is to say, the upper part of the root should only be just covered. The lower roots should be regularly disposed over the convex bottom of the excavation, and carefully strewed with some of the finer portion of soil, over which the other roots may be spread. More soil should then be carefully rather than forcibly introduced. There should be no vacant spaces left, except those of so minute a description that they will be readily filled up by the finer particles of earth washed down by a plentiful watering. This watering should be given when the soil is nearly all filled in; and after the water has subsided so as not to stand above the surface, the latter should be covered with the remaining portion of soil. Except in very loose or light soils, this method will supersede the necessity of the hard beating and *treading in* to which the roots of trees are very generally subjected. The latter practice is now however being laid aside by many, from a conviction of its injurious effects. It is also necessary to remark that a plant should be placed, before the introduction of the soil, exactly as it is intended it should stand; and it should not be pulled from side to side for the purpose of shaking the earth amongst the roots. If the tree be drawn to one side, the fibres of the root will also be drawn towards the same side; but they are of course too flexible to force their way back when the tree is drawn in a contrary direction, and they must therefore become more or less doubled. Nor should the soil be thrown *against* the fibres whilst the roots are being covered; it should be made fine, and either shaken from the spade so as to fall perpendicularly among the roots, or scattered by a force impelling it in the direction of the fibres, which will be in general from the stem towards the extremities, or from the centre to the circumference.

The principles here stated are applicable to the planting of large as well as small trees, and in fact to any terrestrial species of plant. There are however many modifications in practice, some of which may be noticed as proper under certain circumstances, and others as only to be condemned under any circumstances whatever.

Small plants are very frequently inserted by the *dibber*, a cylindrical piece of wood, shod with iron and tapering to a point. This is thrust into the soil, and in the hole formed by this means the roots of the plant are introduced, and a portion of soil pressed towards them by a second stroke of the dibber. It is evident however that by this procedure the roots cannot be in the most natural position; they are in fact the very reverse of being spread out to the best advantage. In the case of very valuable species, the spade or planting-trowel is used in preference to the dibber. The latter has nothing to recommend it on the score of good principles in planting; the expedition with which it can be employed is all that can be said in its favour.

Besides the spade and dibber, various other implements are used in planting, such as the *diamond dibber*, a pointed plate of steel with a short iron handle; a *mattock*, used in stony soils; and some others, adopted according to circumstances. In all cases however where the spade can be used, it is undoubtedly the best instrument. If the soil be unfit for allowing the use of the spade, it should be rendered so previously; and if some time be lost and expense incurred by using it instead of smaller and more expeditious, but at the same more cramping implements as regards the roots, the difference will certainly be ultimately in favour of a proper disposition of the roots by means of the spade.

With regard to the preparation of the soil for plantations, it is found that trenching the ground is attended with profit where it is practised for the purpose of rearing wood for fuel and small timber. This mode of preparation ought likewise to be adopted where trees are intended to be planted for ornament or for shelter. It has not been generally attempted in the case of extensive plantations of heath or rugged mountain-land. It may however be affirmed without hesitation that great advantages would be derived from the operation being more extensively performed. Something more than merely burying the roots of hard-wooded plants is thought necessary, and accordingly *pits* are made. It is scarcely necessary to observe that if these are not of considerable size, the direct progress of the roots is soon obstructed. The time required to form these pits as they ought to be, would be sufficient to regularly trench double their area. The expense of trenching the intermediate spaces will be compensated by the greater return derived from the nurse plants, such as larch, when they come to be removed.

Plantations are generally planted thick in the first instance, and with various species of trees. Larch, Scotch fir or pine, mountain ash, &c. are interspersed amongst the hard wood for shelter, or as nurses. Laburnum is also useful for preserving the other sorts from the depredations of hares, as they prefer the laburnum to every other bark. Nurses are generally left till they are fit for various purposes for which small timber is applicable. They should be planted closer to each other than to the principal trees intended to constitute the more permanent part of the plantation.

After all the care of the planter and the skill with which the operation of removal may have been effected, much of the success of a plantation depends on the proper adaptation of species to the soils and situations most suitable to them. The following remarks upon some of the timber-trees principally cultivated may be useful.

The oak, *Quercus robur*, and *Q. sessiliflora*, prefers strong or even clayey loam; any soil not wet or chalky.

Beech, *Fagus sylvatica*, calcareous soils, gravelly or sandy loam; dislikes stiff clay.

Elm, *Ulmus campestris*, *U. glabra*, *U. montana*, attains, near the banks of rivers, a large size; thrives in most soils.

Ash, *Fraxinus excelsior*, affects a dry subsoil; dislikes a stiff clay.

Plane, *Platanus orientalis*, rich warm soil, tolerably moist, but not retentive.

Sycamore, *Acer Pseudo-Platanus*, *A. platanoides*, best in moist deep soil, but will thrive in others not too stiff; withstands the sea-breeze.

Chestnut, *Castanea vesca*, deep sandy loam.

Walnut, *Juglans regia*, deep loam with a pervious subsoil; dislikes strong clays.

Hickory, *Carya alba*, similar soil to that required by the preceding.

Acacia, or locust-tree, *Robinia pseud-Acacia*, sandy loam; a sheltered situation; cannot bear storms.

Birch, *Betula alba*, forms best timber on dry sandy or gravelly soil.

Laburnum, *Cytisus alpinus*, any soil not too wet.

White Beam, *Pyrus Aria*, any good soil, with a pervious subsoil; dislikes wet clay.

Lime, *Tilia Europæa*, soft deep loam, in low rather moist situations.

Horse-Chestnut, *Æsculus Hippocastanum*, deep loam; not in exposed situations.

Poplar, *Populus alba*, *P. canescens*, *P. nigra*, *P. tremula*, *P. fastigiata*, *P. Græca*, *P. monilifera*. These thrive in almost any soil, but best in that which is deep and rather moist.

Mountain-Ash, *Pyrus Aucuparia*, any soil, wet clay excepted; adapted for high situations.

Alder, *Alnus glutinosa*, moist or even swampy soil.

Willow, *Salix*, of numerous species. Some thrive in rather dry soil, but all prefer moist.

Pine, *Pinus sylvestris*, *P. Laricio*, *P. Pinaster*, *P. Strobus*. The two first are adapted for thin, rocky, gravelly soils; they grow at a great elevation on the warmest sides of mountains, but better in mountain glens; they dislike stiff clay and deep strong loam, and, like all coniferous plants, they do not thrive on chalk. *P. Pinaster* and *P. Strobus* require a less exposed situation than the other two.

Spruce, *Abies excelsa*, *A. alba*, *A. rubra*, *A. nigra*, deep moist soil, in low situations; dislikes thin sandy soil and exposure.

Larch, *Abies Larix*, adapted for thin mountain land, or any soil of which the subsoil is not retentive, excepting however red-sandstone or chalk, as above mentioned.

Cedar of Lebanon, *Abies Cedrus*, any tolerably good soil, rather deeper than for the larch, but a pervious subsoil, free from stagnant water.

Too close planting produces weak drawn-up timber, in consequence of the tops only receiving a due share of light. It is true that the most magnificent trees are found in those antient forests that have never been sown, planted, or thinned by the hand of man. But at the same time it will not be denied, that wherever natural forests exist, the soil and situation must be exceedingly favourable for the species produced; and that although thousands sprung up more than could possibly find room to attain perfection, yet those only that were the most favourably circumstanced and most vigorous would continue; and when once their tops got completely above those of the general mass, the latter must have inevitably fallen into decay. There is no reason however to suppose that those which maintained their ground, and, favoured by propitious soil, became lofty specimens, would not have been benefited by the assistance of the axe to relieve them sooner from their rivals.

If, on the contrary, trees are planted at too great a distance from each other, they are inclined to ramify into large limbs and spreading tops, with a stem short but much thicker than where the space admits of less expansion of foliage. If therefore very thick timber of no great length be required, wide planting is proper; but if tall timber be the object, the plantation must be moderately thick.

The care which plantations require from year to year consists in making up deficiencies, thinning, and pruning. Deficiencies seldom occur if the planting be at first duly performed; and every endeavour should be used to prevent the necessity of *making up*. This is always done with considerable disadvantage to the plants thus introduced, unless the spaces be trenched; but in that case, if the species of tree be properly chosen, the plants may do well in consequence of the shelter afforded by the older surrounding individuals.

Thinning should be commenced in due time. No branch of the temporary trees should by any means overhang the top or even branches of those that are permanent. The shelter on the most exposed sides of the plantation should be formed of robust, vigorous, growing kinds, and it should be allowed to remain unbroken. Plantations that have been neglected till they have formed a dense thicket, must be thinned gradually; for if thinned at once, those left would be injured by the sudden exposure, and would be blown over by winds.

Pruning is an important operation in the management of plantations, but it is often improperly practised tised for want of the knowledge of a few physiological facts, which are essentially necessary to be stated before any rules for pruning can be properly given. If these facts be understood, few rules will be required, but otherwise a volume of directions are liable to be misapplied. It ought therefore to be understood, that the sap ascends the stem chiefly through the alburnum or outer layers of young wood. It then enters the leaves, when it is exposed to the influence of light. Having in consequence undergone an elaboration, it descends on the outside of the alburnum, that is to say through the inner bark, the internal surface of the latter possessing a great degree of lubricity, whereby the passage of a portion of the juices at least is facilitated to the roots; whilst part is detained and becomes organised by the action of the medullary rays, forming a new layer of woody matter. The thickness of the layer so formed is very different in different species; but in the same species, all other circumstances being the same, it is in proportion to the surface of leaves. The aggregate horizontal growth, or in other words the diametrical extension of the stem, branch, and even roots, depends upon the quantity of healthy foliage. The diametrical increase of any particular part corresponds with the greater or less proportion of foliage above that part. Again, it may be stated that if one tree has a clear stem of 20 feet in length, and another has one of 40 feet, the roots and foliage of both being equal, the layer of new wood will be much thinner in the latter case than in the former; for the deposition of woody matter will have to extend over double the surface in the tall tree. It may be also remarked, that, in general, if a tree be left entirely to nature, it will ultimately produce a greater bulk of wood, taking stems and branches together, than would be the case if subjected to pruning. Except however in the case of growing for fuel, pruning is more or less necessary. The value of a timber tree depends chiefly on the stem, the branch timber being of less value. The object to be kept in view in pruning for timber is the production of a clean stem with as small a proportion of branches as possible. But it has been explained that the growth of the stem depends on the quantity of foliage, and without branches a sufficient quantity of foliage cannot be maintained. Whilst, on the one hand, an undue preponderance of branches is prevented by pruning, yet, on the other, as much foliage should be preserved as circumstances will permit.

An excessive privation of foliage should never be occasioned at any one time. It is therefore advisable that pruning should be commenced early, in order, as it were, to repress irregularities in the bud. At all events, whenever an irregularity can be clearly distinguished as such, it should be checked. Thus, when a shoot, occupying the position of a branch, ascends in competition with the top, or leading shoot, and is allowed to go on for years, the stem will have a forked character; or if the competing portion be amputated after it has acquired a large size, the timber will be rendered unsound. But if the shoot from which this aspiring limb took its rise had been stopped in the first or second season of its growth in summer, the tree might have been grown with a clean regularly tapering stem. It is only great irregularities however that should be meddled with during the early growth of the plant; otherwise the increase of roots is prevented, such increase being reciprocal with that of the branches.

Young shoots of the above description may be checked by being shortened in summer; but no large branches should be cut off at that season, nor after the sap begins to flow briskly in spring. Towards autumn however, when the leaves have nearly ceased to carry on their functions, pruning may be very properly performed; and some species, for example the birch and maple, require to be pruned at that time, otherwise they are apt to bleed. The period at which *bleeding*, that is, an extravasation of sap, takes place with greatest force, is immediately before the bursting of the buds in spring. If a branch be cut off when in foliage, the remaining portion draws the sap and prevents effusion at the wound. Some derangement will of course be produced in the flow of sap; and a diminution of the process of lignification and of the formation of roots will be occasioned, owing to the abstraction of a certain extent of foliage. But when the sap is in motion, and the leaves at the same time not expanded, the amputation of a branch is followed by a flow of sap, which appears to drain from every part of the tree. This sap becomes stale on exposure to the air; it then affects the cambium and inner bark, often to a considerable extent below the wound, and if these are not in all cases so far completely killed, yet they are generally more or less injured, and canker is apt to ensue.

Supposing it were required to rear a tree so as to have a stem of clean-grown timber, as tall and as thick as could possibly be obtained in any given time. The first consideration is the root, the plant being supposed to be young, with a top or upright leading shoot, and several side branches. All these should be left undisturbed in the first instance, unless such of the latter as may require a check if growing too strong for the others or for the leader. The laterals should be left, for the sake of the roots, till their presence on the stem becomes inconsistent with the object of producing it as free as possible from knots, taking also into consideration that the difficulty in healing the wound increases as the branches get older. A *few* of the largest shoots should be those first removed. They may be shortened in the first instance after midsummer, and afterwards cut off smoothly by the lowest circular wrinkles which form round their base, close to the stem, but without slicing off a portion of the bark; a slovenly practice, of which only bad pruners are guilty, and which can only have the effect of diminishing the power of the bark to close over the wound necessarily made by the pruning-knife. Such unnecessary wounds cause an extravasation of sap, as may be seen especially in coniferous trees, where they are generally covered with resinous exudations. In the following season the next largest branches should be in like manner displaced, care being still taken, on account of the importance of the foliage, as already explained, that the quantity removed shall be no more than is absolutely necessary.

Small branches along the stem should be left till they approach the dimensions by which the removal of the others is regulated. These principles should be followed up till the required height of stem is attained; after which the branches composing the top should be allowed full freedom, in order to increase, by their organising power, the diameter of the stem.

Coniferous trees require little pruning; nor is it necessary to commence so early with them as in the case of other kinds. In dense forests they are found with straight stems approaching the height of 100 feet clear of side branches, the latter gradually decaying below as they become excluded from light and moisture by those above them. When from this cause the lower branches of coniferous trees are observed to lose in a great measure their vigour, and when their foliage contributes little to the enlargement of the stem, they may then be very properly cut off, without waiting for their actual decay. It is a question whether the branches of these trees should be cut close to the stem at once, in pruning; or whether they should first be *snagged*, that is, cut at some distance from the stem, and either allowed so to remain or be afterwards cut close. That plan is best to adopt by which the least exudation of resinous substance is occasioned, and the blemish soonest overgrown. With the view of preventing the former, the branch may be shortened only to the first live twigs, so as almost to nullify its connection with the stem, preparatory to its final and close removal in the following season.

By choosing the proper season, and by previous shortening, large limbs of any healthy tree may be closely amputated so as to heal over without affecting the tree generally, or even the portion of stem more immediately connected with the limb to any material extent; yet the new layer of wood will prove, on cutting up the timber, to be only in close contact with the surface of the wound, which will remain dead, and with which the living matter enclosing it could not coalesce. A piece of unsound wood is thus embodied. In this case it would be advisable to shorten the limb to such of its laterals as will just be sufficient to keep it alive till the tree is felled. If, in the interval, the branch should push vigorously, means must be adopted to keep it always in a reduced state, by merely allowing as much foliage as will keep the branch alive, without affording any material addition to its diameter.

The proper season for felling trees is when the sap is most at rest. The operation ought not to be performed at any other time, unless for fire-wood. The quantity of sap that may be drawn from some trees is very great. This sap contains the elements of fermentation, the powerful effects of which are evident even on the strong fibre of the oak. Softer woods, although very tough if cut at the proper season, have been observed to crumble to powder in a year or two, in consequence of having been cut when in sap.

With reference to this subject, Miller in his 'Gardeners' Dictionary' (1768), has the following remark: 'Before I quit this subject, I must beg leave to take notice of another great evil, which is of so much consequence to the public as to deserve their utmost attention; which is, that of cutting down the oaks in the spring of the year, at the time the sap is flowing. This is done for the sake of the bark, which will then easily peel off; and for the sake of this, I think there is a law, whereby people are obliged to cut down their timber at this season. But by so doing the timber is not half so durable as that which is fallen in the winter, so that those ships which have been built of this spring-cut timber have decayed more in seven or eight years than others which were built with timber cut in winter have done in twenty or thirty; and this our neighbours the French have experienced, and therefore have wisely ordered that the bark should be taken off the trees standing, at the proper time, but the trees left till the next and sometimes until the second winter before they are cut down; and the timber of these is found to be more durable and better for use than that of any trees which have not been peeled. Therefore I wish we were wise enough to copy after them in those things that are for public good.'

It may be observed, that at the time Miller wrote, the celebrated physiologist Duhamel was inspector-general of marine in France, and had been most probably the means of pointing out the evil, and proposing the remedy above referred to. This plan of barking in the spring and felling in the succeeding autumn is however by no means unobjectionable, and on some accounts is decidedly inferior to felling in autumn or very early in winter without previous disbarking.

(Sang's *Planter's Kalendar*; Loudon's *Arboretum Britannicum*; *Encyclopædia of Gardening*.)

PLANU'DES, MAXIMUS, a Byzantine monk, born, as he himself in one of his works says, at Nicomedia. The time of his birth is unknown, and almost the only circumstance of his life which is beyond doubt is that in the year 1327 he was sent on an embassy to Venice by the emperor Andronicus the elder. At this time he must have been of a mature age. That he was still alive in 1340 is evident from a letter still extant, which he wrote to the emperor Joannes Palæologus, who ascended the throne in that year. D'Orville places his death in the year 1353, for which however he adduces no testimony. Gerhard Vossius prolongs his life to the year 1370; and others still later. Towards the close of his life Planudes is said to have been imprisoned on account of his partiality for the doctrines of the church of Rome; and when afterwards compelled to write against that church, to have done so in such a manner and with such feeble arguments that Cardinal Bessarion declared that the heart of Planudes had no share in what he had written on that occasion.

We are indebted to Planudes for the preservation of a number of valuable Greek poems. He made a collection of Greek epigrams, in seven books, extracted from the comprehensive Anthology, in fifteen books, which Constantinus Cephalas had compiled in the tenth century. Planudes, in his collection, omitted those poems which seemed to him obscene or of little importance. This collection, though the compiler had displayed little taste or discernment, was, at the time of the revival of letters in Italy, the only one which was known, and was first printed, in 1494, at Florence, by John Lascaris. This edition was reprinted at Venice in 1503, and at Florence in 1519. A better edition, and with some additional poems, was published by H. Stephanus, at Paris, in 1566, which was likewise reprinted several times. It has been translated into Latin by Grotius. In 1606, Salmasius discovered, in the Palatine library at Heidelberg, a MS. belonging to the tenth century, which contained the complete Anthology of Constantinus Cephalas, upon which our present 'Anthologia Græca,' revised by Brunck, and edited by Fr. Jacobs, is based. Planudes also made a collection of fables, ascribed to Æsop, to which he prefixed a Life of the father of fabulists, which is full of absurdities. Some of the fables which are attributed to Æsop by good and antient authorities are not found in this collection, whereas others which cannot possibly belong to him are incorporated in it. There are two MSS. of this collection of fables, one of which is in the king's library at Paris. [Æsop.] Planudes also made a translation of the 'Metamorphoses' of Ovid into Greek prose, which was edited, in 1822, by Boissonade; also a Greek translation of Cæsar's 'Gallic War,' which was printed by Jungermann in his edition of Cæsar, Frankf., 1606; but it is a disputed point whether this is the translation of Planudes. Most of his other translations, such as that of some works of St. Augustin, and Macrobius on the Dream of Scipio, as well as his numerous original works, partly on theological, partly on scientific, and partly on grammatical and rhetorical subjects, have never been thought worth being published, and are scattered in various libraries. His literary character on the whole is low; he wanted perseverance and honesty, and was guilty of several forgeries, especially in his 'Anthology,' his 'Life of Æsop,' and the collection of fables ascribed to him.

PLASTIC CLAY. The lower part of the Tertiary series of England and France yields, with green-sands and pebbles, beds of red, white, or mottled clay, often of excellent quality for the potter. The series of beds related to these clays and sands has received the name of plastic-clay formation, but, by a large view of its geological and zoological characters, it may be ranked in the same group as the London clay, and thus be contained in the Eocene deposits of Lyell.

PLATA, RIO DE LA, is a large river in South America, or rather this term is only applied to the wide æstuary formed by the confluence of the rivers Paraná and Uraguay. Where this river enters the sea, between Punta del Este and Cape S. Antonio, its width is not less than 120 miles; and between Punta de las Pedras and the Barrancas de Santa Lucia above Monte Video, it is still 53 miles wide; but above these places the shores gradually approach nearer, and opposite Colonia they are hardly 20 miles apart. The æstuary continues to preserve this width to the confluence of the two large rivers which fall into it. This æstuary is very shallow. At its mouth it is only ten fathoms deep on an average, and this depth gradually decreases. Opposite Monte Video the average depth is not more than three fathoms; and this may be considered the average depth of the La Plata to Buenos Ayres; so that vessels drawing more than 16 feet of water cannot run up farther than that town. The deep part of the river opposite Buenos Ayres is from seven to eight miles from that town: this part is called the outer roads, and between them and the inner roads there is a sand-bank. Smaller vessels anchor in the latter at from one to two miles from the shore. The navigation of this æstuary is very difficult, owing to the very dangerous shoals, the strong and irregular currents, and the sudden tempests to which it is subject. Between Monte Video and Buenos Ayres there are four banks, Lara Bank, Santiago Bank, Ortiz Bank, and Chico Bank, of which the third is very extensive. When the river is low, there are only from seven to nine feet of water on them. The currents are extremely irregular and strong, a circumstance easily accounted for, when it is considered that the larger of the two tributaries, the Paraná, rises within the tropics and during the rainy season brings down an immense volume of water, and that the wide expanse of the æstuary, being bounded either by low and level or very slightly elevated ground, is subject to be influenced by every strong wind which drives a great volume of water to the point of the compass opposite to that from which it blows. The effect produced in this respect by the pamperos, or south-western gales, which frequently blow with inconceivable fury, is very great. Singular fluctuations in the depth of the water occur before and after these pamperos. For some days before them the river rises, and is always higher than usual when the south-west wind begins; but after a few hours the water falls rapidly, and vessels are left aground. Instances are known of the upper part of the æstuary, opposite Buenos Ayres, having been so much affected by strong south-westerly or westerly winds, that men have ridden several miles into its bed to places where ships usually anchor: accordingly, it is not unusual for the water to fall in the outer road of Buenos Ayres, in less than twelve hours, from six to two fathoms in places where the usual depth is four fathoms. All these circumstances must render the navigation of this æstuary extremely difficult and dangerous, and hence it is called El Infierno de los Marineros; but Captain Fitzroy enumerates its redeeming qualities also in having anchoring-ground everywhere, and soundings where the indications are certain if the vessel is approaching danger, as the bottom is hard on and near the banks, while in the deeper water it is very soft. Little or no tide has been hitherto noticed in this wide expanse of water, but Captain Fitzroy thinks that 'this anomaly may be more apparent than real; for where the depth of water is so fluctuating and the currents are so variable, it is difficult to distinguish the precise effect of tides, except by a series of observations far longer than has yet been made.'

Through this æstuary the commercial produce of about one-fourth of South America is brought to the market of the world. It is therefore a great advantage to the countries from which the æstuary of the Plata receives its waters, that the rivers which flow into it offer less obstruction to navigation than is usual in large streams. The largest of these rivers, the Paraná, is navigable for vessels of 300 tons as far as the island of Apipé, situated between the state of Corrientes and Paraguay, where the river runs westward, a distance of about 750 miles from its mouth. The Rio Paraguay, the largest affluent of the Paraná, may be navigated by large boats nearly to its source, at least to 16° N. lat., which is more than 800 miles above its confluence with the Paraná, in a straight line, and perhaps not less than 1200 miles measured along the bends of the river. The Rio Pilcomayo is too shallow for navigation, but the Rio Vermejo, another affluent of the Paraguay, is navigable from its mouth upwards to the confluence of its two principal branches, the Lavayen and Rio de Tarija below Oran, a distance of more than 400 miles above its confluence with the Paraguay. The Salado, which joins the Paraná in its lower course, is navigable to the town of Matara, which is at least 350 miles from the mouth of the river. The Uraguay, another large river which falls into the La Plata, is less suitable to navigation, as two cataracts occur about 180 miles above its mouth, which cannot be passed, except when the water is at its highest level.

(*Surveying Voyages of the Adventure and Beagle;* Parish's *Buenos Ayres, and the Provinces of the Rio de la Plata;* and Ignacio Nuñez, *Account of the United Provinces of the Rio de la Plata.*)

PLATA, LA. *The Provinces of the Rio de la Plata*, also called the *Argentine Republic* (*Republica Argentina*), comprehend a large part of the surface of South America. The river Cusu Leubu, or Rio Negro, has lately been fixed as their southern boundary: the mouth of this river is near 41° S. lat. On the north, where the republic borders on Bolivia, the parallel of 22° S. lat. chiefly constitutes the boundary-line. Thus the country extends from 41° to 22° S. lat., a distance of 1320 miles in a straight line. On the west, the highest part of the Andes divides it from Chile and the Bolivian province of Atacama; and on the east it is separated from Paraguay by the course of the Rio Paraguay, and from Brazil and Banda Oriental (Uraguay) by the Rio Uraguay. On the east, the boundary-line lies near 58° W. long., except a comparatively narrow tract, which projects between the Paraná and Uraguay as far as 54° W. long. On the west the boundary-line, south of 30° S. lat., is near 70° W. long.; but farther north it declines to the east, and at the north-western corner of the country it coincides with 68° W. long. The average width is about 620 miles. The whole surface is calculated to be 726,000 square miles, or nearly three times and a half the extent of France, and nearly six times and a half that of the British Islands.

Surface and Soil.—About one-sixth of the surface of this country is mountainous: the remainder consists of wide plains, on which are scattered a few isolated ranges of hills, and an extensive system of low mountains, called the Sierra de Cordova.

I. *Mountains, and Countries enclosed by them.*—The mountainous countries lie on and along the eastern declivity of the Andes. This mountain-range, which traverses South America in all its length, from the Strait of Magalhaens to the Isthmus of Panama and the neighbourhood of the Caribbean Sea, is of comparatively moderate width south of 30° S. lat., hardly exceeding anywhere 100 or 120 miles; but north of that parallel the eastern side spreads out into an extensive mountain-region, the eastern border of which is more than 400 miles distant from the western declivity of the range.

The Andes from 40° S. lat., where they begin to constitute the western boundary of the Argentine Republic, dividing it from Chile, to 37° S. lat., are very little known. They seem to be composed of two parallel ranges, about 30 or 40 miles distant from each other, of which the western is supposed to be the more elevated. A considerable part of the western range rises above the snow-line, which in these parts occurs about 10,000 feet above the sea-level, and among its summits there are three volcanoes. The most southern, the Volcano de Villa Rica, or Cerro Imperial (39° 10′ S. lat.), attains an elevation of more than 16,000 feet, the sides, to a great distance below the summit, being always covered with snow. Farther north is the Volcano de Cura (38° S. lat.). These two volcanoes are in the western range. In the eastern is the Volcano de Unalavquen (37° 10′ S. lat.).

Farther north, between 37° and 34° S. lat., it is known that the Andes consist of two parallel ranges, which in some places approach one another within 30 or 40 miles, and at others are 70 or 80 miles apart. The eastern range is imperfectly known, but does not attain such an elevation as the western, no part of it apparently being covered with perpetual snow, except between 36° and 35° S. lat., where a Cerro Nevado is marked on Parish's map. This range is known to contain one volcano, that of Pomahuida (near 36° 15′), which had three eruptions between 1820 and 1830, and a terrible one in 1822. In the western range, which in its whole extent forms the watershed between the rivers that run to the Pacific and Atlantic oceans, and is therefore considered as the boundary between Chile and the Argentine Republic, many summits rise far above the snow-line, and four among them are volcanoes, the Volcanoes de Antuco (36° 50′ S. lat.), de Chillan (36° 5′ S. lat.), de Peteroa, or Curico (35° S. lat.), and de Rancagua (34° 10′). A much greater number of volcanoes is marked on our maps, but it has not been ascertained that they really are volcanoes. The general elevation of this portion of the Andes may be from 12,000 to 13,000 feet above the sea, and consequently it approaches the snow-line, as is shown by the mountain-passes by which this part of the Andes is traversed. The most southern of these passes, that of Antuco, near the volcano of that name, rises in its highest part above the line of vegetation. The Planchon pass (about 35° 10′ S. lat.) is much lower, as there is vegetation upon it; and it probably does not exceed 11,000 feet. The third pass, called Il Passo de las Damas, occurs near 34° 50′, and as it is clothed with vegetation even at its most elevated point, it is supposed not to rise above 11,000 feet.

Between 34° and 33° S. lat., the two ranges of the Andes are not far distant from each other, and they enclose the elevated valley of Tunuyan, which is about twenty miles wide, and 7500 feet above the sea-level. The ranges, which run nearly north and south on each side of the valley, attain nearly double that elevation. The pass called Portillo, which traverses the valley obliquely, rises on the western chain of the Andes to 13,210 feet, and on the eastern to to 14,365 feet. This pass is only open from the beginning of January to the end of April, being blocked up by snow the remainder of the year. South of this pass is the Volcano de Maypu, or Peuquenes, which is above 15,000 feet high, and always covered with snow.

Between 33° and 30° S. lat., the two ranges of the Andes recede from one another to the distance of forty or fifty miles. Between these ranges is the valley of Uspallata, which is about 180 miles long and 40 miles wide, of which width about 15 miles are level ground, and the remainder consists of hills, which skirt both ranges. The level part of the valley is 6200 feet above the sea-level. Near 32° S. lat. the valley is traversed by some higher ground, which runs east and west, and from which the Rio de Mendoza runs southward, and the Rio de S. Juan northward. The former stream finds its way to the eastern plains by a cleft in the mountains near 33° S. lat., and the second by a similar passage near 31°. The soil of the valley is sterile, and impregnated with salt, except towards the northern extremity, where it is fertile. The range of the Andes which is east of the valley is called the Paramilla Mountains: it is about 10,000 feet high, and is partly covered with wood. The great chain of the Andes, west of the valley of Uspallata, occupies between 50 and 60 miles in width, and consists of four or five parallel masses of rocks, divided from one another by ravines or glens. The highest summits of these rocky masses may attain the elevation of nearly 14,000 or 15,000 feet, as there is snow in the ravines even in April. The road which leads over them, and in the highest part is called La Cumbre, attains an elevation of 12,454 feet, and is passable by mules from the commencement of November to the end of May, but the remainder of the year it can only be travelled by foot-passengers, and with considerable danger, being then blocked up by snow. On the northern side of the road is the Volcano de Aconcagua, the highest of the known volcanoes on the globe, rising 23,200 feet above the sea-level: it is within the boundary of the Argentine Republic.

North of 30° S. lat. the Andes assume a different character. As far north as 28° S. lat. they consist of three parallel but unconnected ranges. The western range forms one continuous mass of mountains with those which lie farther south and north, but the central and eastern ranges rise rather abruptly from the plains along the eastern side of the Andes near 30° S. lat., and they terminate as abruptly near 28° S. lat. The three ranges, together with the wide intervening valleys, occupy a space of more than 120 miles in width. The western range, which alone is called the Andes, does not rise above the snow-line. No volcano occurs in this mountain-mass; and indeed no volcano is ascertained as occurring between the volcano of Aconcagua (32° 13′ S. lat.) and that of Atacama (21° 36′). The Andes in this part not being so high as they are farther south, several easy passes lead over them, but they are only used occasionally, the country along the Pacific being nearly a desert. The central range is called Sierra Famatina, from the celebrated silver-mines which are found on its eastern declivity. South of 29° S. lat. the Famatina Mountains rise to a considerable elevation, though short of the snow-line; but north of 29° S. lat. there is an enormous mass of rocks, the summit of which, being covered with perpetual snow, is called the Cerro Nevado. On the eastern declivity of this mountain-mass are the mines. The eastern range of the mountains, called Sierra Velasco, preserves nearly an equal elevation in its whole extent, and its height probably falls short of 8000 feet, as it is rarely covered with snow even in winter. It is only about 3000 feet above the valley of Famatina. The valley which lies between the Andes and the Sierra Famatina is called the Vale of Guandacol: it is about 140 miles long, and 24 miles wide. A river, called the Bermejo, rises at the most northern extremity of the valley, and traverses it in a southern direction, until it reaches a point south of 30°, when it runs round the southern extremity of the Sierra Famatina, and entering the plain is either lost in the sandy surface of that tract or finds its way to the lakes of Guanacache. The valley of Guandacol is stated to be very favourable to the growth of wheat. There are some rich copper-mines, which are not much worked, because of the difficulty of bringing the metal to a market. The inhabitants are aborigines, who do not speak the Quichua language, and who partly live on the vicuña, whose skins supply an article of exportation to other provinces, where ponchos (cloaks) and hats are made of them. They have orchards, and cultivate small patches of ground. The valley of Famatina, which is enclosed by the Sierra Famatina and Sierra Velasco, is about the same length, but somewhat narrower, being hardly 20 miles wide. No stream runs through it. The southern half is a complete desert without water. The soil is sandy, and in many places covered with salt. In the neighbourhood of the Cerro Nevado, the rills of water which descend from the mountains form small rivers, which run to the plains, and supply the means of irrigation. As the soil of these parts is clayey and retentive of moisture, many tracts of moderate extent are cultivated, and produce Indian corn, peas, and trefoil clover, and several culinary plants, as artichokes, cauliflowers and cabbages, and excellent pumpkins. The hamlets are surrounded by vines, fig, peach, and orange-trees. The potato is indigenous in the Famatina mountains. From 6000 to 8000 barrels of wine are annually exported from this valley to Rioja, and thence to the other provinces of the republic. The climate of this valley is rather hot in summer; from December to February the thermometer in the hottest part of the day varies between 80° and 106°, and in winter (June and July) it probably does not descend below 50°, as no snow falls on the Sierra Velasco, which is 3000 feet above the valley. Heavy rain is uncommon, but snow is frequent, and at all seasons, on the Sierra Famatina. Thunder-storms also are common, and accompanied by very large hailstones. In winter, a wind from the north, called *sonda*, sometimes blows with great force, and produces the effect of a sirocco; it raises the thermometer to 90°.

North of 28° S. lat., the Andes cover an immense extent of country east of the high range which runs parallel to the Pacific. The south-eastern edge of this mountain-region follows a line beginning at the northern extremity of the Sierra Velasco, and running in a north-eastern direction to a place on the Rio Vermejo, about fifty miles below the confluence of the two rivers Lavayen and Rio de Tarija, its two principal branches. Between 24° and 21° S. lat., the eastern border is near 62° W. long. The northern part of the mountain-region is without the countries that belong to the Argentine Republic, and included in Bolivia, where the snow-capped Alturas de Lipez form its northern border. The descent of the Andes towards the Pacific terminates it on the west. The highest part of this extensive region, which lies between 65° and 68° W. long., and between 25° and 22° N. lat., is very properly called El Despoblado, or the uninhabited country. Its elevation has not been determined, but it is very probable that it rather exceeds than falls short of 13,000 feet above the sea. This elevation may be inferred from the total want of every kind of cultivation; even the quinoa appears not to succeed. It is however scantily covered with grass, on which numerous herds of alpacas and vicuñas find pasture, and chinchillas subsist. These animals, with a small quantity of gold collected in some rivers, and salt, which covers a large part of the surface, supply to the few Indian families dispersed over this inhospitable region the scanty means of subsistence. They also bring snow from the mountains to the towns in the valleys farther east. The surface of this tract presents no great variety of level, and is crossed by a road which leads from the town of Salta to Atacama in Bolivia. Though the whole region rises to so great an elevation, no part of it is covered with perpetual snow. Even the chain of the Andes, which constitutes its western border, does not contain one single summit which rises considerably above the general elevation of the whole mass.

The countries which surround the Despoblado on the south and east vary greatly in their level. From the southern border of the Despoblado, between 67° and 68° W. long., a range branches off, which runs south-south-east, and is called Sierra Ambato and Sierra Ancasta. It terminates north of 28° S. lat., nearly in the parallel of the northern extremity of the Sierra Velasco, but about one hundred miles east of it. The country between this lateral range and the principal range of the Andes is traversed by another chain in all its length, which however does not appear to rise to such an elevation as the Sierra Ambato. The valleys which lie between those chains are very imperfectly known, but their climate is described as hot and sultry, and this is apparent from the staple articles consisting of very good cotton and red pepper. The inhabitants cultivate wheat, and have herds of cattle, which find good pasture on the adjacent mountains.

From the eastern declivity of the Sierra Ambato, near 26° 45′, the Sierra de Aconquija extends in an east-north-east direction to the Rio Salado, on the banks of which it terminates at a point called El Passage (near 23° S. lat.), where the river runs southward. This range is very high in the vicinity of the Sierra Ambato, where a portion of it is always covered with snow; but farther east it sinks much lower, though it perhaps never falls below 10,000 feet above the sea-level. Opposite its eastern extremity, and on the left bank of the Rio Salado, there begins another range, which may be considered its continuation, as it runs in the same direction, and preserves the same general elevation. This range, which is called Sierra Lumbre, or Santa Barbara, terminates in some hills on the banks of the Rio Vermejo, several miles below the confluence of its two principal branches, the Rio Lavayen and the Rio de Tarija. A third range branches off from the eastern border of the Despoblado, near 22° 40′ S. lat.: it has at first the form of an elevated and wide range, and is called Abra de Cortaderas. Farther east it forms a table-land of great extent, called the Table-land of Yavi. Neither the range nor the table-land rises above the snow-line, but their general level can hardly be less than 12,000 feet above the sea, as both rise above the line of trees. The table-land, though a complete level, is destitute even of bushes, and severe frost is experienced on it in the month of June. It is only inhabited by guanacoes and vicuñas: it terminates with a steep descent on the Rio de Tarija, near 22° S. lat.

The countries enclosed between the eastern border of the Despoblado and the Abra de Cortaderas and the Table-land of Yavi on the north, and the Sierra de Aconquija and Lumbre on the south-east, consist chiefly of high table-lands. This elevated mountain-region is furrowed by a few deep, wide, and very long valleys, which, being much depressed below the general level of the region, are comparatively well-cultivated and populous. The longest of these valleys is that which is watered by the Rio Guachipas or the upper course of the Rio Salto. It begins at its upper extremity, on a depression of the Despoblado itself, near the small town of Acay, in the vicinity of which are some silver-mines, and it extends nearly a hundred miles southward, when it meets the Sierra de Aconquija, and the valley and the river turn to the north-east by east. Near the Despoblado the vale is too high to be fit for agriculture, and in these parts it is very narrow. But before it turns to the north-east it widens considerably, and the cultivation of the European cerealia begins. Large quantities of maize and wheat are grown, and the quantity of these articles exported to the other valleys is considerable. The rich pastures on the adjacent mountains support great numbers of cattle, horses, and mules. There are also extensive plantations of European trees, and much common wine is made, which finds a ready sale in the neighbouring districts.

The Vale of the Rio Guachipas terminates in the Plain of Salta, which extends about twenty miles in every direction. Another valley runs northward from this plain to the Abra de Cortaderas, a distance of about 150 miles. Through this valley lies the road which leads from Salta to Potosi, and it has excited the admiration of all travellers on account of its great length, its comparatively small width, and the steepness with which the rocks rise on both sides. In many places the valley is hardly a furlong wide. This valley may be called the Valley of Jujuy, as the town of that name is situated nearly at equal distances from both extremities of it. The wide valley of the Rio Lavayen, or Rio de Jujuy, branches off from the Valley of Jujuy, and extends more than 100 miles between the Sierra Lumbre and an elevated table-land to the north of it. It is much wider than the Valley of Jujuy, and the settlements are much more numerous here than in the other valleys. In these valleys tropical vegetation appears in all its luxuriance. Forests of large trees cover the banks of the rivers and ascend the hills to a considerable elevation. Besides maize, large quantities of sugar-cane are grown and exported. In the lower parts the coca (*Erythroxylon Coca*) grows, whose leaves are chewed by the natives, and the maté, or Paraguay tea-plant, is indigenous.

Along the south-eastern declivity of the Sierra de Aconquija and Sierra Lumbre there is a tract of considerable width, called the Plain of Tucuman, which is very fertile, and has a pleasant and healthy climate. The surface is furrowed by numerous small rivers, which originate on the declivity and at the foot of the ranges, and descend in a south-eastern direction to the lower country, which is farther east. This region is an inclined plain, which sinks to the south-east with an almost imperceptible slope. Having a hot but dry and healthy climate, and abundance of water for irrigation, it is the most fertile tract of the Argentine Republic, and is thence called the Garden of the Rio de la Plata. Its width south of the Rio Salado exceeds 70 miles, but between that river and the Rio Vermejo it is much less. The population of this plain, which is very great, is mostly occupied in raising corn, rice, maize, and tobacco. Much tobacco is exported. The sugar-cane is said to grow naturally in the low lands. The base and slope of the mountains are covered with tall trees, and supply pasture for cattle.

II. *Plains.*—The plains occupy about five-sixths of the surface of the provinces of La Plata. The most northern part of them, which is known under the name of El Gran Chaco, extends on the east of the mountain-region as far as the banks of the Rio Paraguay, and from the northern boundary of the republic to the confluence of the Rio Salado with the Parana, occupying all the tract between these rivers. This immense country, which is about one-sixth of the whole Argentine Republic, or 120,000 square miles, is very little known, there being only a few families, and those mostly of Indian origin, settled on the banks of the rivers. The interior is possessed by several aboriginal tribes, who wander about in the woods, and live on the produce of the chace and wild fruits. The most northern part of the desert appears to have annual rains, and the country is accordingly pretty well wooded. In this part, which lies between the Rio Vermejo and the Rio Paraguay on both sides of the Rio Pilcomayo, and which is called the Llanos de Manso, there is a considerable number of independent tribes, though the several families are generally small. The southern portion of the Gran Chaco, between 26° and 30° S. lat., is a complete desert for want of rain and water. The general character of the soil is sandy, and in many places it is covered with incrustations of salt; in others it is interspersed with small salt-swamps. No part of it produces grass, but some tracts are covered with stunted prickly trees. It is uninhabited, except on the banks of the Rio Salado, where a few families have settled.

The country which lies west of the southern portion of the Chaco, and extends to the banks of the Rio Dulce, though not considered as forming a part of it, does not materially differ from it in features, soil, and vegetation, except along the banks of the Rio Dulce, the water of which, being sweet, can be used for irrigation, and is in many places used for that purpose.

West of the Rio Dulce and between 28° 30′ and 30° S. lat., a desert extends as far west as the neighbourhood of the Sierra Velasco, from which it is separated by a fertile tract, called La Costa, hardly 20 miles wide. Where the desert is traversed by the road between Cordova and Santiago del Estero, near its eastern extremity, it is about 60 miles wide, but farther west it grows much wider. The surface is level, here and there interspersed with hillocks; for the most part covered with a thick salt efflorescence. Hence the desert has obtained the name of Great Salina. The vegetation is limited to a kind of salsola, from the ashes of which soda is extracted. This desert is probably the hottest part of America, the heat during the prevalence of the northern winds in summer being almost insupportable in those places which are built on the borders of this desert, as Santiago del Estero. This may be mainly attributed to the nature of the soil, but partly to the lowness of the country, it having been ascertained, by barometrical observations, that the surface of the desert is only a few feet above the level of the sea at the town of Buenos Ayres, though it is 700 miles distant from that point.

That part of the plain which lies between 30° and 33° S. lat. exhibits a different character. Nearly in the middle of it is the Sierra de Cordova, a system of heights, which in another place would be called mountains, but in the neighbourhood of the snow-capped Andes can only be called hills. It was formerly supposed that this sierra was connected with the Andes, but it has been ascertained that a plain 200 miles wide lies between them. The more elevated and mountainous part of this system is between 30° and 32° S. lat., and extends more than 120 miles from north to south, but the width does not exceed 50 miles. The southern part, between 31° and 32°, is a small table-land, about 30 miles wide, and growing narrower towards the south. The declivity is gentle towards the base, but near the top it is steep. The plain is covered with grass, but is entirely devoid of trees. It may be about 2500 or 3000 feet elevated above its base, and perhaps 3500 or 4000 feet above the sea-level. In winter it is sprinkled with patches of snow. The short valleys, by which the western side is furrowed, produce abundance of maize and fruits, and this is also the case with the long valley, which runs along the eastern unbroken declivity. Near 32° S. lat. the table-land branches off into two ridges, of which the eastern is called the Sierra and the western the Serrazuela. They run north and north-westerly, and at their northern extremity are more than 50 miles from each other. The intervening country is a succession of stony or sandy ridges flat at the top, and alternating with broad pastoral valleys interspersed with plantations of fig and peach trees.

The country which extends from the Sierra de Cordova to the Rio Paraná is hilly, or strongly undulating along the base of the heights, and produces good crops of Indian corn in the lower tracts where the fields can be irrigated. This hilly country extends about thirty miles, when the country sinks into somewhat irregular plains. Some parts of these plains are covered with trees, but others are without wood, which becomes more scarce as we proceed farther east, until the woods re-appear at some distance from the banks of the Paraná. These woods chiefly consist of low mimosas or stunted prickly trees. The plains are generally covered with coarse grass, but in some parts, especially in the eastern districts, the soil is impregnated with salt. The numerous small streams which flow from the eastern declivity of the Sierra de Cordova, and unite into three rivers, the Primero, Segundo, and Tercero, do not join the Paraná, but are lost in small salt lakes, with the exception of the Tercero, which however, in the dry season, is very shallow, and has hardly water enough for small boats. The Rio Dulce, a large river which rises in the Sierra de Aconquija, and runs about 400 miles, is likewise lost in an extensive salt lake, called Laguna Salados de los Porongos. The salt lakes in which these rivers are lost occur between 30° and 32°, and are near the meridian of 62° W. It seems that a deep depression runs along this meridian, and that the country between it and the Rio Paraná and Rio Salado is much more elevated. There are agricultural settlements in this country on the banks of the rivers, and small hamlets, inhabited by herdsmen, occur on the plains. Though the pasture is indifferent, a considerable number of cattle are reared. The country which surrounds the southern extremity of the Sierra de Cordova, and extends to 33° S. lat., resembles in its general character that which is to the east of it, except that it is traversed in several places by narrow ridges of low rocky hills, along the bases of which vegetation is much more vigorous, and the soil more favourable to agriculture than in the wide plains which lie between them.

The country which lies on the west of the Sierra de Cordova, and extends in that direction for 120 or 130 miles from the range, is nearly altogether bare of grass. Rain is scarce in all the countries of South America south of 24°, and this want of moisture is the chief reason why cultivation extends so slowly in these parts. In the country west of the Sierra of Cordova it never rains, nor is the ground ever refreshed by dew, which falls abundantly in the pampas farther to the south-east. The soil of this region is composed of a loose and friable clayey loam, and the greater part of it contains stunted trees; tracts covered with salt incrustations, or with grass, are only occasionally met with, and never occupy a large surface. The grassy tracts are most numerous near the southern extremity of the Sierra Velasco, where they are called Los Llanos, and supply pasture for numerous herds of cattle.

That part of the plain which extends from 33° S. lat. to the banks of the Rio Negro, the southern boundary of the Argentine Republic, is known under the name of Pampas. Though generally considered as one plain, extending on a perfect level from the shores of the Atlantic to the base of the Andes, it has been observed that nature has divided it by some tracts of more elevated ground into several regions, which differ in soil and fertility. The most remarkable and best known of these elevated grounds begins on the shores of the Atlantic between Cape Corrientes and Punta Andres, south of 38° S. lat., with rocks, which at some distance from the sea rise to the height of hills, having broad summits in the form of a table-land, and steep sides. This range of hills, which is called the Sierra del Vuulcan (opening), is only a few hundred feet high, and has excellent pasture on its summit. About 40 miles from the sea the ridge is interrupted by a wide gap or opening (called by the aborigiues Vuulcan), and on the west of this opening rises another ridge, which has various names, being broken by several other gaps, and extends in a south-eastern and north-western direction about 200 miles from the Atlantic. Where this elevated ground approaches 61° W. long., it turns to the north, and runs in that direction to 35° S. lat., when it turns more to the west, and may be said to terminate where the parallel of 34° cuts the meridian of 62°. This part of the higher ground is a gentle swell, overtopped by low hills, which occur at great distances from one another, and by a few low ridges. Though most travellers describe the country north of 34° in the direction of this swell as a perfect level, it is somewhat higher than the plains lying east and west, and it extends to the banks of the Rio Paraná, where the river is lined with cliffs about sixty feet above its level, between S. Nicolas and Rosario. This elevated ground separates the eastern portion of the pampas from that farther west. All the rivers which water these eastern pampas have their origin in this elevated tract. It is remarkable that the water of most of them is salt, especially in summer, when the volume is much diminished, though they flow through a country which is not impregnated with saline matter. From this it may be inferred that extensive deposits of salt must exist in the high ground on which they originate.

The Rio Salado, which rises near the point where the parallel of 34° cuts the meridian of 62°, runs in an east-south-eastern direction about 300 miles, and divides the *Eastern Pampas* into two nearly equal parts. Though numerous settlements have been made in the country north of the Rio Salado, by far the greatest part of it is still in its natural state. It is a continuous level plain, covered with coarse luxuriant grass, growing in tufts and partially mixed with wild oats and trefoil. Extensive tracts are entirely overgrown with thistles from six to eight feet high, which are used for fuel, as the country is entirely devoid of trees and shrubs. Near the dwellings of the inhabitants, only single trees are met with. The level plain contains shallow depressions, in which the rain-water is collected and forms pools. This water evaporating in the dry season, these depressions are then covered with rich grass, which supplies pasture during the hot weather. Thus this country is able to maintain immense herds of cattle and horses; and it is observed that the coarse grass and the thistle gradually disappear when trodden down by the animals, and are replaced by a fine turf; this is especially observable in the neighbourhood of the town of Buenos Ayres. Though the rearing of cattle is still the principal object of agriculture, sheep have much increased of late years, and wheat has been more cultivated. The latter is now grown to such an extent, that not only the importation from the United States of North America has been entirely stopped, but flour and corn have been shipped to Brazil: wool also forms an important article of export. Though the rivers are dry in summer, except the Rio Salado and the largest of its affluents, whose water cannot be used on account of its saltness, fresh water may be procured at no great depth by digging wells. Along the banks of the La Plata and Rio Paraná, between Buenos Ayres and the small town of S. Pedro, there is a broad belt of low ground, which is annually inundated by the freshets of the Rio Paraná for several months, and fertilised by the muddy deposit of that river.

The country south of the Rio Salado is of a somewhat different character. Near the banks of the river it is on a level with the country north of it, which it resembles in every respect; but about ten miles from the river swamps begin, which extend over a great part of this region. Towards the sea the swamps are nearly 100 miles wide; but farther west they grow narrower, until they terminate at the confluence of the Rio Salado with the Rio Flores. These swamps are thickly set with tall canes and reeds, and in many places interspersed with small lakes and ponds. They probably owe their existence to the circumstance of their surface constituting a perfect level, which receives numerous streams, the waters of which cannot make their way to the Rio Salado or to the sea. These swamps form a great obstacle to the extension of agricultural settlements; for though the country along the base of the Sierra del Vuulcan and the more western ranges of hills appears in no respect to be inferior in fertility to the country north of the Rio Salado, no agricultural settlements have been established here.

North of the Bahia Blanca (near 39° S. lat.) a mountain of considerable elevation rises abruptly over the plain: it is called Sierra Ventana, and its elevation above the sea-level is about 3500 feet. This mountain extends north-west for about 20 miles, but grows lower towards the west, where it is separated by a depression from another and lower ridge, that runs in the same direction, and is called Sierra Guamini. So far this country is known, but farther west it has not been explored. It is however known that in the same direction there occurs a vast forest, three days' journey long, which covers a hilly tract, and other forests of a similar description occur in the centre of the Pampas, and lie in the same direction.

The country between the Sierra del Vuulcan and the Sierra Ventana and the ridges dependent on them, resembles in its natural features the country south of the Rio Salado. Along the base of the Sierra Ventana extends a level country, interspersed with some low hills; the surface is dry, and fit for agricultural establishments. But in approaching the chain of the Sierra de Vuulcan, Darwin found the country, to the width of 80 miles, covered with swamps. In some parts there were fine moist plains, covered with grass, while others had a soft, black, and peaty soil. There were also many extensive but shallow lakes, and large beds of reeds. He compares this tract with the better part of the Cambridgeshire fens. These swamps probably owe their origin to the rivers which descend with a rapid course from the Sierra Ventana and Sierra Guamini to the level country.

The greatest part of the *Western Pampas*, namely, all the country west of 62° W. long., and extending thence to the Andes between 34° S. lat. and the Rio Negro, is almost unknown, having only been explored along the courses of the rivers, except in one line, in which it has been traversed by land. The few points which have thus been examined are too isolated to authorise us to form an idea of the capabilities of this immense country. But we are well acquainted with that portion of the plain which lies between 33° and 34° S. lat., as it is traversed by the great road that leads from Buenos Ayres to Mendoza, and thence over the Andes to Chile.

In the country which surrounds the sources of the Rio Salado, the soil of the plain begins to be impregnated with muriate of soda, and continues more or less so to the base of the Andes. But it has a different character east and west of 66° W. long. East of that meridian, a great part of the surface is covered with extensive saline swamps overgrown with reeds; the more elevated spots of these swamps are covered with a saline efflorescence. The dry tracts which intervene between the swamps are overgrown with a coarse grass that attains a height of six feet, and resembles rye or wild oats. This grass grows in clumps, and is salt to the taste. The soil consists of a dark friable mould, without the smallest pebble in it. In every part of this country there are lakes containing salt water. Many of them are from 10 to 20 miles long, and nearly as wide. These lakes are most numerous between 64° and 65° W. long., where an extensive shallow depression occurs, perhaps 50 miles in length and 20 in width. The whole of this depression is filled with water, when the Rio Quinto, which originates in the Sierra de Cordova, is raised by a freshet from the mountains, at which time it sends a great portion of its waters into this depression. When the water has been evaporated by the heat of the summer, it only remains in the numerous lakes and ponds with which the depression is interspersed. Where the plain approaches the hilly country that surrounds the south side of the Sierra de Cordova, the surface is broken in many places into low hills, with a steep ascent and furrowed by ravines; the hills are separated from each other by grassy plains. The grass is smooth, short, and thick, and there are low bushes on it. The hills are partly clothed with thorny trees of a stunted growth, and with brushwood. The rivers which intersect this country run in beds from 20 to 40 feet below its surface; their banks are very steep, but during the greater part of the year there is no water in them. It is only in the hilly tract of this part of the Western Pampas that there are any agricultural settlements: in the level country there are only cattle-farms.

The plain which extends from 66° W. long., to the base of the Andes presents a less level surface. The soil consists of loose sand, impregnated with saline matter, and unfit for the growth of grass. The vegetation is limited to low thorny trees, some resinous bushes, and saline barilla plants. But this arid and sterile soil, when irrigated, is changed into the most fertile fields. The saline matter, as it seems, when applied to a soil so light, becomes by the assistance of constant moisture the most active stimulus to vegetation, and serves as a never-failing manure. The rivers in this region, being very little depressed below the general surface of the plain, are extensively used for irrigation, and the settlements on the Rio Tunuyan, Rio de Mendoza, and Rio de S. Juan are rather numerous, and rapidly increasing in extent and number. Indian corn and wheat are grown to a great extent, and exported to the neighbouring countries. The soil seems particularly adapted to fruit-trees. The plantations of vines, figs, peaches, apples, olives, and nuts are very extensive, and their produce goes to the neighbouring countries, especially to Chile.

The Argentine Republic contains also an extensive tract of hilly country, which lies between the rivers Paraná and Uraguay. In the northern part of this region is the Laguna de Ybera, which extends from north to south in some places nearly 100 miles, and nowhere less than 40; and from east to west about 80 miles. It covers an area of more than 3000 square miles. A narrow strip of elevated ground divides its northern border from the Rio Paraná, and it is supposed that it is supplied with water from that river by infiltration, as no stream enters it, and it supplies with water four small rivers, one of which, the Mirinay, runs to the Uraguay, and three others to the Paraná. The surface of this low tract however is only a deep swamp, interspersed with numerous small lakes. It is chiefly covered by aquatic plants and shrubs, but in most parts it is impassable The country extending southward from this lake to the confluence of the Paraná with the Uraguay has an undulating surface, the heights seldom rising into hills, except in the interior and at a few places along the Paraná. It is chiefly overgrown with trees, between which there are some savannas of moderate extent. On the plains numerous herds of cattle are pastured, which constitute the wealth of the country. Though the trees are of stunted growth, the entire want of forests in the surrounding countries makes this wood of great demand for the ordinary purposes of cabinet-work, carriages, and as timber for small houses. The interior of the country appears to be much more hilly than along the rivers, and is occupied by the forest of Monteil, which extends more than 100 miles from north to south, with an average width of 40 miles. It is encumbered with brushwood and studded with small trees. At the southern extremity of the country, along the banks of the Paraná, there is a low tract, which is subject to occasional inundations. That portion of this country which extends from the lake of Ybera in a north-eastern direction to the boundary-line of Brazil, is known under the name of the Missiones, from the circumstance of the Jesuits having collected here a great number of aborigines, and accustomed them to a civilised life. The south-western part, which is undulating, has a soil of great fertility, producing cotton, sugar, and other tropical productions. To the north-east of it, the country rises into high hills and mountains, which are covered with high timber-trees, the most southern which occur east of the Andes from the Strait of Magalhaens.

Rivers.—All the rivers which drain the Argentine Republic, as far as it is situated north of 34° S. lat., carry their waters to the wide æstuary called La Plata. [PLATA, RIO DE LA.] Before they reach this fresh-water sea, they form two large rivers, the Paraná and the Uraguay. The Paraná originates hardly twenty miles from the shores of the Atlantic, on the table-land of BRAZIL. [Vol. v., p. 357.] After leaving that country at its confluence with the river Iguasú, the Paraná continues to run between the Argentine Republic and Paraguay in a southern direction for about 50 miles, when it gradually turns to the south-west, and continues in that direction to the large island of Apipé, a distance of about 100 miles. This part of the river is not navigable in all its extent, as there are several rapids and small falls, the last in the neighbourhood of the island of Apipé. This large island, with whose dimensions we are not acquainted, is the point where the uninterrupted navigation of the Paraná begins, and where large quantities of timber are shipped, the river being navigable for vessels of 300 tons burden. From Apipé the river runs westward nearly 100 miles, when it is joined by the Rio Paraguay from the north, and at the point of confluence it suddenly turns to the west of south. Below the junction with the Paraguay, the width of the river varies from one mile and a *half* to two miles, but the whole volume of water seldom flows in one channel, as the current is divided by a continuous series of islands overgrown with low trees and subject to inundations. These islands and the numerous sand-banks render the navigation slow and tedious. At Santa Fé the river begins to divide into various branches, and to run southward. After a course of about 100 miles it turns to the south-east at Rosario, and thence to its mouth in the La Plata the number of its branches increases. It opens into the La Plata with a large number of embouchures, forming a long but comparatively narrow delta, composed of a great number of islands. The most northern branches fall into the wide mouth of the Rio Uraguay. Its principal outlet is that which is called Paraná Guazú (the Great Paraná), in which there is seldom less than two fathoms and a half of water. The mouth called Paraná de las Palmas is the deepest, next to the Guazú. The Paraná runs nearly 900 miles within the boundary of the republic, of which 750 miles are navigable for vessels of 300 tons all the year round. From July to December the river preserves its natural level, but towards the end of the year, the intertropical rains having filled the upper branches, it begins to rise, and continues to do so for four months, to the end of April. The average rise below its junction with the Paraguay is stated to be 12 feet. It then inundates the adjacent grounds, especially below Santa Fé, and the tracts which are thus laid under water are said to cover a surface of 4000 square miles, an estimate which is perhaps overrated. The water leaves behind a grey slimy deposit, which is very favourable to vegetation. At the end of April the water begins to fall, and the fall is somewhat more rapid than the rise.

The Paraguay, the largest of the affluents of the Paraná, originates likewise in Brazil. [Vol. v., p. 356.] Having passed through the Estrecho de S. Francisco (20° S. lat.), at the Fecho dos Morros, it continues to flow with a gentle current in a southern direction, dividing Paraguay from the Gran Chaco, until, at 25° 30′ S. lat., and about 20 miles below Asuncion in Paraguay, the channel is narrowed at a place called Angostura by protruding rocks, between which the current runs with great rapidity. From this point it runs west by south to its junction with the Paraná. Vessels of considerable size may navigate this river within the boundaries of the republic, through which it runs about 400 miles. The channel in these parts being confined between high banks, the water rises 30 feet, but the inundations of the adjacent tracts are not extensive. Its waters are increased by two large tributaries, the Pilcomayo and Rio Vermejo. The Pilcomayo rises in the Andes, in two branches. The southern, called Rio de S. Junan and afterwards Pilaya, originates in the Despoblado; and the northern, the proper Pilcomayo, derives its waters from the numerous rivers which descend from the Andes between the Despoblado and the vale of the Desaguadero in Bolivia, and partly also from those which originate in the mountains that enclose that vale. These two rivers receive the drainage of the eastern declivity of the Andes between 19° and 23° S. lat., and unite after a course of about 350 miles, near 20° 40′ S. lat. and 62° 50′ W. long. After the union of these branches the Pilcomayo is a broad and deep river, and runs about 700 miles to its junction with the Paraguay, first easterly and afterwards to the south-east. In this part of its course it flows with innumerable windings through the Gran Chaco, where it is joined by no large river, and where its waters are gradually absorbed by the arid country through which it runs. Thus it becomes extremely shallow, and neither of the two arms into which it divides 200 miles above its mouth is navigable, even for small boats, to a distance exceeding 100 miles from the Paraguay. These two arms are called Araguay Guazu and Mini. The Vermejo derives its waters from the Despoblado, the Abra de Cortaderas, and the table-land of Yavi, descending from which elevated regions it forms two rivers, the Rio de Tarija on the north, and the Rio Lavayen on the south. The first, turning southward, joins the second at the eastern base of the table-land of Yavi, and both form the Vermejo, which flows about 700 miles through the Gran Chaco with numerous windings, until it joins the Rio Paraguay nearly 40 miles above its confluence with the Paraná. The Rio Vermejo is navigable for large boats as far as the union of its great branches.

The largest affluent of the Paraná, next to the Paraguay, is the Salado. This river rises on the southern border of the table-land of the Despoblado under the name of Cachi, and runs southward until it meets the river Santa Maria, which comes from the Sierra de Aconquija, when it turns east by north, and is called Guachipas. Having drained the valley of that name, it enters the plain of Salta, where it is joined by some smaller rivers, and turns south-west, flowing through the opening between the Sierra de Aconquija and Sierra Lumbre, where it is called 'El Passage.' At this place it is traversed by the road leading from Cordova to Salta, and is fordable in the dry season, but during the rains the passage is so dangerous that all communication between the southern and northern provinces is interrupted. A few miles farther south it enters the desert country, where the waters imbibe a brackish taste, from which its name is derived, and which it preserves the whole way to its junction with the Paraná near Santa Fé. Its course through the plains is more than 800 miles, of which about one-half, as far up as the small town of Matara, is said to be navigable.

There is a peculiar system of drainage in the western Pampas along the base of the Andes, between 31° and 36° S. lat. The waters which descend between these parallels from the eastern declivity of the mountains are collected in three systems of lakes, united by channels by which the surplus water is carried from one system of lakes to the other. As these channels lie from north to south, it is obvious that the northern system is the most elevated, and the southern the lowest. The most northern, called the lakes of Guanacache, occurs between 31° 40′ and 32°. Neither the number nor the extent of these lakes is exactly known. Their margins are covered with salt incrustations during the winter and spring. These lakes receive two fresh-water rivers, the Rio de S. Juan and the Rio de Mendoza, both of which rise in the Vale of Uspallata between the two ranges of the Andes. The Rio de S. Juan drains the northern part of the vale for about 100 miles, breaks through the Paramilla range near 31° S. lat., flows eastward about 50 miles, and then southward a somewhat greater distance. Its waters in the plain are used for irrigation. The Rio de Mendoza, or de Luxan, drains the southern districts of the Vale of Uspallata for about 50 miles, then turns eastward, passing by a chasm through the Paramilla range, and then declining to the north, it likewise reaches the lakes of Guanacache. The waters of this river also are used for irrigation. It is supposed that the Rio Vermejo, which waters the Vale of Guandacol, also reaches the lakes of Guanacache by a southern course; but the waters of this river, which are fresh in the vale, imbibe a brackish taste in the salt plains which it traverses after issuing from the vale. From the lakes of Guanacache a river issues, which at first runs east and then south, and, after a course of about 250 miles, falls into the second system of lakes, those of the Bevedero. This river is called the Desaguadero, and flowing through a level country slightly elevated above its banks, it expands in some places to a great width, converting the adjacent tracts into salt swamps. The water of this river is only fresh during the early season of the year (from December to March), when the snow on the Andes melts; during the remainder of the year it is salt, and its banks are covered with saline incrustations. The lakes of the Bevedero are likewise imperfectly known, both as to number and extent. The name Bevedero properly applies only to the most northern of these; the waters are salt for nine months of the year, and on its banks salt is collected for sale in that season. These lakes lie between 33° 30′ and 34° 30′ S. lat. and between 66° and 67° W. long., and, besides the Desaguadero, receive the waters of the Tunuyan. This river drains the vale of the same name, which is enclosed by two ranges of the Andes, breaks through the eastern chain below the Portillo pass, then runs through the plain, first northward and afterwards eastward, falling into the lakes of the Bevedero after a course exceeding 200 miles. Its waters are used for irrigation. All the waters of the Rio Tunuyan do not reach the lakes, but a portion of them is carried southward by an arm called Rio Nuevo, which falls into the Rio Diamante. The country between the lakes of the Bevedero and the Rio Nuevo being very low and level, the lakes, when swelled by the increased supply of water during the melting of the snow on the Andes, inundate this intermediate tract, and discharge their waters into the Rio Nuevo, which must therefore be considered as the drain of these lakes. The Rio Diamante rises on the eastern declivity of the peak of Cauquenes, a snow-capped summit of the Andes, and runs eastward for about 150 miles, when it is joined by the Rio Nuevo. Formerly it did not unite with that river, but joined the Rio Atuel: in the year 1812 it changed its course. After the junction with the Rio Nuevo, it flows southward under the name of the Rio Salado, or Desaguadero del Diamante, and after a course of about 150 miles more, it joins the Chadi Leubu. The last-mentioned river is very little known. Its principal affluent seems to be the Atuel, which rises south of the volcano of Peteroa, and flows eastward. After its junction with the Desaguadero del Diamante, it runs about 36 miles, and is then lost in the Urre Lauquen, a lake of considerable extent, but very imperfectly known, in 37° S. lat.: its waters are very salt, whence it derives its name, which, in the language of the Ranqueles, signifies bitter lake.

Of the rivers falling into the Atlantic south of the La Plata, we have mentioned the Rio Salado of Buenos Ayres, which is unfit both for irrigation and navigation. The Cobu Leubu, or Rio Colorado, was until lately almost entirely unknown, but it is now ascertained that it rises in the Andes, and flows without interruption to the sea. It is said that it is navigable only about 100 miles from its mouth. Near the mouth it divides into several arms, including an extensive delta. In December it is much swollen and runs with great rapidity. The Cusu Leubu, or Rio Negro, which now is considered to constitute the southern boundary of the Argentine Republic, rises within the range of the Andes in two branches; the Catapuliche, which runs south, and the Limay Leubu, or Rio de la Encarnacion, which flows north. After a course of from 80 to 100 miles, these two rivers join and break through the eastern range of the mountains by an easterly course, preserving the name Limay Leubu. After running about 100 miles north-north-east, the river is joined from the north by the Neuquen, a large affluent, which is said to be navigable for small craft more than 200 miles: after this junction the Limay Leubu takes the name of Cusu Leubu. The remainder of its course lies in an eastern and south-eastern direction for more than 400 miles. This river is navigable for large boats to the place where the two principal branches unite within the ranges of the Andes.

Climate.—The great differences of level within the territories of the Argentine Republic produce a very different climate in the various regions of which it is composed. It is very probable that the difference of heat and cold felt on the table-land of the Despoblado and the countries surrounding the Great Salina is the greatest that occurs on the American continent, though these regions are less than 300 miles from each other. We are not further acquainted with the Despoblado than that it does not admit of any kind of cultivation, which renders it probable that it is only about 1500 feet below the snow-line, and continually exposed to frost. Respecting the climate of Santiago del Estero, Temple says, that in December, 1825, during three or four days and with a hot northerly wind, the heat was so great that it blistered the skin on the face and hands even of those who remained in doors; that leaves fell scorched from the trees, and the bark of several became cracked and shrivelled just as if fire had been applied; and that the bolts, locks, and keys of the doors were so hot that they could not be retained in the hand. The inhabitants were afraid they should die by suffocation. The climate of the other parts of the country is between these two extremes; but as by far the greatest part extends in wide plains and most of the valleys are low, their climate is rather hot than cold, and in most places the summer heat is oppressive, being from 90° to 100°. As to rain, it is remarkable that, in the countries extending along the base of the Andes where rain falls, it generally does not come down in autumn and winter, as in the southern countries of Europe, but in spring, from October to January. No particular observations on the climate of these countries have been published, except some with respect to the Eastern and Western Pampas. The heat experienced in both is about the same, there being some slight frost in July and August, but there is a great difference in regard to rain and the moisture of the air. In the Western Pampas the air is extremely dry, and there is no dew at night; rain also is very scarce. But the Eastern Pampas are a very wet country. Rain occurs all the year round, and a heavy dew falls every night. In these parts sudden changes of the atmosphere are not rare; sometimes they raise or depress the thermometer 20 or even 30 degrees in a few hours. The abundance of moisture in the air and the sudden changes from heat to cold are due to the winds. During the greater part of the year the prevailing winds are northerly; and they bring with them the heated air of the lower latitudes, and, in passing over low and inundated tracts, take up a great deal of moisture; so that on arriving at the Eastern Pampas, the united effect of heat and moisture produces unpleasant impressions, like those of the sirocco of the Levant, causing lassitude and relaxation, though rarely disease. Then suddenly bursts out a *pampero*, or south-west wind, which, blowing over the immense extent of the dry pampas and proceeding from the Andes, rages with incredible fury, and is more like a West India hurricane than the gales experienced in countries without the tropics. The pamperos are sometimes accompanied by awful thunder-storms, and frequently by clouds of dust so dense as to produce darkness. They generally last only a quarter of an hour. But in 1793 one blew without intermission for three days, and the bed of the La Plata was laid dry for a distance of 10 miles from the shore, and many vessels which had been sunk years before in the river were visited by the inhabitants, who walked about in the bed of the stream without wetting their feet. The pampero however precipitates the moisture of the air, and restores to it its usual degree of elasticity. At Buenos Ayres the thermometer rose, in January, 1822, to 94°, and in August it sunk to 36°. The mean temperature of the year was about 62°; that of the summer (January, February, and March), 72°; of the autumn (April, May, and July), 58°; that of the winter, 54°; that of the spring (October, November, and December), 65½°.

A part of the pampas is subject to periodical drought of long duration, especially the north-eastern corner of the Western Pampas, which includes the northern part of the province of Buenos Ayres and the southern of Santa Fé. For three years (1827-30) so little rain fell, that even the thistles failed, and the whole country assumed the appearance of a dusty high road. Vast numbers of birds, wild animals, cattle, and horses perished for want of food and water. The lowest estimate of the loss of cattle in the province of Buenos Ayres alone was one million head. According to information collected by Darwin from the natives, these droughts are periodical, and occur at intervals of about fifteen years.

Productions.—Respecting the principal objects of agriculture, the Argentine Republic may be divided into two regions, which are separated from each other by the Gran Salina. On the north of it they partake of the intertropical productions: mandioc, rice, Indian corn, and the coca plant are cultivated in most of the lower valleys. In the more elevated tracts, tobacco and cotton succeed well, and are cultivated on a large scale. South of the Gran Salina the agriculture resembles that of southern Europe, except that no rice is raised. Wheat and Indian corn are the principal crops, but barley and lucerne are also extensively grown, especially near Mendoza. The northern region also produces some wild plants of great use, such as the algaroba tree, from the fruit of which, mixed with maize, the Indians make cakes, and by fermentation, *chica*, an intoxicating spirit; the quinaquina, the palm-tree, the plant from which the Paraguay tea, or maté, is taken, the cactus that bears the cochineal insect, the aloe from which yarn and ropes are made, and the indigo and some other plants used in dyeing. In the Gran Salina itself a kind of salsola grows from which soda is extracted. The fruit-trees which are cultivated are mostly those of southern Europe, as the vine, orange, fig, olive, peach, apricot, apple, and pear. On the banks of the Paraná *seda sylvestre* (wild silk) is collected, which is left in the woods by a certain caterpillar.

Though the cultivation of wheat has increased so much that it now forms an article of exportation, the principal exchangeable wealth of the republic is derived from their herds of cattle. The number of heads is above four millions, of which the province of Buenos Ayres alone is said to possess three. They wander about in the pampas nearly in a wild state, and the largest items in the list of exports consist of hides, hair, horns, tallow, and jerked beef. The horses, mules, and asses probably exceed two millions; they are exported to the West Indies and the island of Mauritius. Some attention has lately been paid to the rearing of sheep, and wool has of late years been exported to a considerable amount: goats and hogs are less common. Most of the South American wild animals are found in the republic, as the puma, the jaguar, the armadillo, the tapir, the tajassoo, the biscacho (a kind of rabbit, which is very numerous, and whose skins have lately been brought to England for furs), deer, and some kinds of monkeys. The guanaco is found in the plains and on the mountains, but the wild llamas, vicuñas, and alpacas only in the cold regions on the elevated table-lands. The water-hog, or carpincho (*Hydrochoerus Capybara*), the largest of the rodent animals in the world, is very common on the banks of the Paraná; Darwin shot one which weighed 98 pounds. The most common birds are the emu, the condor, green parrots, wild ducks, pigeons and quails, the carrion-vulture, and several other rapacious birds. Serpents are not numerous, but there are many kinds of noxious insects, venomous spiders, bugs or bencualas, fleas, musquitos, and nignas. Locusts, as in all countries where arid plains are found, frequently destroy the crops. Bees are common in the countries along the Andes and on the Paraná, and wax is collected in several districts. The cochineal insect is reared on the banks of the Salado. Along the coast south of the La Plata, whales, sea-lions, and sea-elephants are numerous. Among the insects is one called clavillo from its resemblance to a little nail; it is smaller than the cochineal, and occurs only in Catamarca and Tucuman, where it is used for dyeing green the vicuña and alpaca wool.

Gold and silver occur in the Andes, and also in the Sierra de Cordova, but they are generally situated at such an elevation above the plains, that there is neither food nor fuel in their neighbourhood, and as the ore is not rich, they cannot be worked with advantage. Some of the mines are worked on a small scale. It is said that iron and lead are found in the republic. Salt is abundant in the Great Salina and south of it, with the exception of the Eastern Pampas; and rock-salt is said to occur along the eastern declivity of the Andes south of the Diamante river. In the same locality coal is also said to abound.

Inhabitants.—The population of the Argentine Republic consists of descendants of Spaniards, and of Indians. The whites have not settled here as masters, as in other countries farther north, where they have exempted themselves from agricultural labour. They are here cultivators of the ground, and chiefly look after cattle and horses. Those who look after the horses, and are called *gauchos*, live a wild life, and can hardly be said to be superior to the Indians. Their dress is a cloak (poncho), and they live exclusively on beef.

The Indians who are subject to the dominion of the whites are far from being numerous: the number probably falls short of 30,000 individuals. They are only found in the provinces north of the Great Salina. On the Despoblado and in the valleys surrounding it, they seem to belong to the Peruvian nation, and to speak the Quichua language. In the valleys of Caxamarca and Rioja they form distinct tribes, and live in villages distinct from the whites; their language is not the Quichua. Several families of the Guarani are still settled in the Missiones, and others established themselves in Corrientes and Entre Rios, after the expulsion of the Jesuits in 1767. The Indians who are not subject to the whites, and who are frequently at war with them, may be divided into the Northern and Southern Indians. The former inhabit the Gran Chaco, between the Rio Salado and the Paraguay and Paraná, and the latter the countries south of 35° S. lat. Only one independent nation has maintained its ground surrounded by settlements of the whites, the Guaycurus, who inhabit the country between the towns of Cordova and Santa Fé and as far north as the great lake called Laguna Salados de los Porongos. Twenty years ago this tribe was composed of only 800 or 900 individuals, and since that time they have probably been reduced to a still smaller number by the civil wars in the provinces; they seem to belong to the great nation of the Guaycurus, which inhabits the western banks of the Paraguay between 16° and 26° S. lat., and has rendered itself formidable both to the Spaniards and Portuguese. They have great numbers of horses, and dwell in low houses constructed of hides, which they move about with great facility. The attempts made to settle them in fixed places have hitherto proved abortive, as they are much attached to a wandering life.

The number of Indians in the southern districts of the Gran Chaco is small, and it seems that there are only a few families in the neighbourhood of the rivers. But on the banks of the Rio Vermejo and between it and the Paraná there is a great number of wandering tribes, some of which are powerful. The most numerous of these tribes are the Tobas, Mataguayos, and Matacos on the banks of the Vermejo, and the Guanas, Guaycurus, Yagas, Lenguas, and Ivirayaras between the Pilcomayo and Paraná. All these, with the exception of the Guanas and Matacos, adhere to a nomadic life, and live on the produce of their flocks and of the chace. They have also many horses. The men go naked, with the exception of a girdle of cotton round their loins; the women cover themselves with a large cotton cloth. The men are always on horseback. Most of these nations seem to belong to the race from which the Guaycurus have sprung, and all their languages are only dialects of one. They raise some Indian corn. The Matacos, who had been for some time under the care of the Jesuits, have fixed habitations, cultivate the ground, and a considerable number of them go every year in harvest-time to the province of Salta, where they are employed in getting in the crops. Though these northern tribes have generally not a friendly intercourse with the whites who are settled near them, they are not in a state of continual war with them, as is the case with the southern Indians. Though in most other respects they resemble the southern tribes, they are not so tall, and on the average not taller than the inhabitants of southern Europe.

The southern tribes have their pasture-grounds south of the Rio Salado of Buenos Ayres, and of 35° S. lat., which line was established in 1740 between them and the Spanish government. This line was secured on the side of the Spaniards by a few military posts, and, though the Indians from time to time made predatory incursions into the settlements, the whites lived in a state of comparative security. But during the confusion with which the establishment of the political independence of these provinces was attended, and during the war with Brazil, the Indians, becoming bolder, laid waste the country as far north as the Sierra de Cordova, killing the men, and making women and children captives. After several attempts to bring about a peaceful arrangement had failed, the government of Buenos Ayres sent a strong force against them, under the command of Rosas, the present dictator of Buenos Ayres, who scoured (from 1832 to 1835) the whole country as far south as the Cusu Leubu, killed many thousands of the Indians, and rescued 1500 whites who had been captured in the predatory expeditions of the natives. These active measures seem to have had a good effect, and at the same time the country as far south as the Cusu Leubu was annexed to the Argentine Republic. The Indians must accordingly now consider that they are only permitted to inhabit these countries with the consent of the republic. These southern tribes are divided into innumerable petty tribes or families, each governed by its own cacique, or *ulmene*, who occasionally claims by hereditary title, but has little authority, except in time of war, when all submit implicitly to his direction. These tribes are frequently quarrelling and fighting with one another, and are only united in their predatory excursions against the whites. They speak a common language, and seem to descend from the same stock as the Araucanians in Southern Chile. All these tribes are comprehended under three denominations: the Pehuelches (Pine-tree Indians) inhabit the Andes and the mountainous and hilly country along its eastern declivity; the Ranqueles (Thistle Indians) occupy the central plains, and are more troublesome than the others to their neighbours; the Puelches inhabit the country along the Atlantic, between the Rio Salado of Buenos Ayres and about 300 miles inland. This last-mentioned division of Indians is now on friendly terms with the whites. They are a tall race, averaging near six feet in height. They have numerous herds of horses. They eat the flesh of the mares and colts, and only occasionally eat bread of maize, which they obtain from the Spaniards in exchange for salt and cattle, and blankets made by their women. Their dwellings are made of hides sown together, and are easily moved. They are always wandering about in the wide plains in quest of pasture for their horses. All of them, men, women, and children, live more on horseback than on foot.

Political Divisions and Population.—Under the Spanish dominion, the countries now comprehended within the Argentine Republic were divided into four intendencias, Buenos Ayres, Cordova, Tucuman, and Salta. When these countries obtained their independence, a new division was made in 1813 and 1814, but as the physical character of the country had not been attended to in making this division, some of the new states again divided: at present there are thirteen republics. It was originally intended to unite them all under a central government, but the attempt that was made did not succeed. The states were dissatisfied with the authority and influence of the central government in their internal affairs, and they ceased to send deputies to the congress. We may therefore consider the Argentine republic as an aggregate of thirteen republics, quite unconnected with one another; and it is probable that for some time they will form no union. The nature of the country renders any union by conquest very difficult, and in many cases impossible. Each of the thirteen states is separated from its neighbour by extensive tracts either of desert or at least of uncultivated country, to penetrate which even with a small army is extremely dangerous. Though there has been some fighting among them for several years, we do not find that any two of these republics have united in one government. But the friends of liberty have to complain of another consequence of this division of the country into numerous small states. Deprived of assistance from their neighbours, most of them have already fallen under the authority of individuals, called dictators. To use the proper term, despotic governments have taken the place of republican institutions. In such circumstances it can hardly be hoped that republican institutions will again be formed, and perhaps the present despotism may assume the mild form of a monarchical government, and bring about a more uniform administration.

The estimated population of the provinces of the Rio de la Plata, in 1836-1837, according to Parish, is as follows:—

Buenos Ayres from .	180,000	to	200,000
Santa Fé	15,000	„	20,000
Entre Rios . . .	30,000	„	30,000
Corrientes . . .	35,000	„	40,000
Cordova	80,000	„	85,000
Santiago	45,000	„	50,000
Tucuman	40,000	„	45,000
Salta	50,000	„	60,000
Catamarca . . .	30,000	„	35,000
La Rioja	18,000	„	20,000
San Luis	20,000	„	25,000
Mendoza	35,000	„	40,000
San Juan . . .	22,000	„	25,000
	600,000	to	675,000

This is exclusive of independent Indians within the territory claimed by the republic.

States and Towns.—1. *Buenos Ayres*, the largest and most populous of the republics, has lately extended its southern boundary to the Bahia Blanca, a deep inlet and good harbour near 39° S. lat., and has a coast-line along the La Plata and the Atlantic above 600 miles in length, which however contains no harbour for large vessels, except that of the city of Buenos Ayres [BUENOS AYRES; PLATA, RIO DE LA], near the most northern, and that of Bahia Blanca at the southern extremity of the coast-line. That of Buenos Ayres is bad, but Bahia Blanca is a good one. The new boundary-line on the west runs northward from Bahia Blanca to Fort Melinque, curving eastward, and on this side the state is surrounded by countries which are still in the possession of the native tribes, no whites residing west of the line. A line drawn east-north-east from Melinque to the Arroyo del Medio divides it from the state of Santa Fé. The surface is estimated at 75,000 square miles, about 8000 less than the island of Great Britain. The whole country is a level plain, with the exception of the districts adjacent to the western line, which are somewhat hilly, and the ranges of the Sierras del Vuulcan and Ventana and those connected with them, which traverse the southern districts. A large portion of it is fit for agriculture, and by far the largest part of the articles exported from Buenos Ayres are drawn from this province, especially cattle, sheep, wool, and corn. All the inhabitants north of the Rio Salado are of Spanish origin, but the countries south of the river are mostly occupied by tribes belonging to the Puelches. The remains of extinct species of large animals, as those of the megatherium, are often found in the western districts. As this state alone has a coast-line, and consequently is thus brought into connection with foreign nations, the provincial government, though not by an express agreement, carries on the business of the Argentine Republic with foreign powers. The executive, according to the constitution, consists of a governor, or captain-general, as he is styled, aided by a council of ministers appointed by himself. He is responsible to the Junta, or legislative assembly, by whom he is elected. The Junta itself consists of 44 deputies, one half of whom are annually renewed by the people. But this constitution can hardly be said to exist, since Rosas, as dictator for life, has taken all the power into his own hands.

There is no town of importance in this state, except Buenos Ayres. [BUENOS AYRES.] S. Pedro and S. Nicolas, which are on the banks of the Rio Paraná, contain only from 500 to 800 inhabitants.

2. *Santa Fé* extends along the Rio Paraná from the Arroyo del Medio to the confluence of that river with the Rio Salado, and afterwards along the latter stream northward to an undetermined point in the desert. It is divided from Cordova by the low uncultivated tract in which the Laguna Salados de los Porongos is situated, and in which the rivers Primero and Segundo are lost. The southern is the only boundary which is not formed by a desert, the most southern settlements being contiguous to those of Buenos Ayres. But a large part of the surface is unfit for agriculture, though it supplies indifferent pasture for cattle. Cattle and mules are exported. It was some years since devastated by the Guaycuru Indians, who live within its boundaries, but this tribe is now nearly extinct. Among the inhabitants there are many of Guarani origin, who settled here after the expulsion of the Jesuits in 1768. Lopez has been dictator of this republic for many years. The town of Santa Fé, a meanly-built place, is on the Rio Salado, about 12 or 14 miles above its mouth; it consists of a square, and eight streets branching off at right angles from the corners of it, and contains between 4000 and 5000 inhabitants. It was formerly the entrepôt of the goods which were exchanged between the western states and Paraguay, but that branch of commerce has entirely failed, since Paraguay has broken off all connection with the adjacent countries. Of late it has established some overland trade with Monte Video, from which it receives foreign goods. Rosario, on the high precipitous banks of the Parana, has above 1000 inhabitants.

3. *Entre Rios*, so called from being situated between the rivers Uraguay and Paraná, comprehends only the southern portion of the country so situated, the boundary-line between it and Corrientes being formed by the rivers Guayquirara and Mocoreta, between 30° and 30° 30′ S. lat. The former falls into the Paraná, and the latter into the Uraguay. It has the great advantage of being abundantly watered by numerous small streams, and has extensive forests which supply fire-wood and materials for carpenters' work. The soil is in general fertile, and covered with luxuriant herbage, on which numerous herds of cattle pasture. Except a few families of Guarani origin, the country is inhabited by the descendants of Spaniards. Its government still preserves republican forms. The capital, Bajada, or Villa del Parana, which is situated on the eastern banks of the Parana and nearly opposite Santa Fé, is built on the top of a lofty gently-sloping cliff, whence it derives its name Bajada de Santa Fé, or the Descent to Santa Fé. It exports great quantities of hides and tallow, and contains about 6000 inhabitants. Concepcion de la China, on the banks of the Rio Uraguay, is a small place, with 1500 or 2000 inhabitants, and some trade with Monte Video.

4. *Corrientes* comprehends the northern portion of the peninsula formed by the two rivers Paraná and Uraguay. The soil is fertile and the climate warm. The principal productions are sugar, cotton, and tobacco; but these articles are only exported to a small amount. Rice and indigo are also grown. Within this state is the lake of Ybera. The capital, Corrientes, is situated below the confluence of the Rio Paraná with the Paraguay, and stands on a considerable elevation. It is rather well built, and contains 4500 inhabitants. Santa Lucia is also a place of some importance on the Paraná, with a population of about 2000.

The *Missiones*, which, according to the treaty between Brazil and Buenos Ayres, in 1828, are to constitute an independent republic, extend eastward from Corrientes, between the Paraná and Paraguay to the confines of Brazil. This fertile tract, which was very populous under the sway of the Jesuits, is now filled with ruins, and contained but a few thousand inhabitants before 1825; many of them perished in the following war, and others emigrated. They were of Guarani origin, and this country and Paraguay was the native country of that once numerous tribe of aborigines. Nothing is known respecting its present political condition and its population.

5. *Cordova*, the most important of the states, next to Buenos Ayres, comprehends the Sierra de Cordova and the surrounding hilly country, with some adjacent plains. It is divided by the Gran Salina from Santiago, Catamarca, and Rioja, and by a travesia, or desert country overgrown with stunted prickly trees, from San Juan. A sterile and thinly inhabited country lies between it and San Luis. On the south it extends to the country of the Indian tribes. The low sterile tract in which the rivers Segundo and Primero are lost, and the Laguna Salados de los Porongos is situated, separates it from Santa Fé. Thus it is much more fertile than all the countries which surround it. Numerous rivers descend from the Sierra de Cordova, but all are lost in the desert, with the exception of the Rio Tercero, which, during part of the year, with difficulty finds its way to the bed of the Carcarañal, which falls into the Paraná near Santo Espiritu below Santa Fé. This river would be navigable for six or eight months in the year, but for two small rapids, which however might easily be removed. The valleys within the Cordova mountains, and those which extend along their sides, have a fertile soil, and

maize and fruits are raised there in abundance, but the plains, as well as the declivities of the mountains, are only fit for pasture. Cattle and sheep constitute the principal wealth of the republic; hides and wool are exported to Buenos Ayres. Cordova, the capital, is built on the banks of the Rio Primero, in a narrow valley considerably depressed below the general surface of the country. Thus it is sheltered from the north and south winds, which, blowing alternately on the higher grounds, produce sudden changes in the atmosphere which are injurious to health. The town has a population of 14,000 inhabitants. The streets are regularly laid out, and the houses are built of brick, and better than in other towns in the interior; most of them have balconies. In the centre of the town is a spacious square, on one side of which is a neat town-hall, and on the other a fine cathedral. There are also ten other well-built churches, and a university erected by the Jesuits, which in former times was famous, but is now hardly better than a provincial college. This town was formerly the depôt of the European merchandise intended to be sent to Peru, but this branch of commerce no longer exists. The commercial connections of Cordova do not extend beyond Buenos Ayres. Alta Gracia, a neat town near the base of the Sierra de Cordova, contains 3000 inhabitants.

6. *Santiago* is of great extent, comprehending the western part of the Gran Salina, the country between the Rio Dulce and the Rio Salado, south of 27° 30′, and also a large tract of the Gran Chaco, to the east of the last-mentioned river. But the good land is of comparatively small extent, and almost entirely limited to a narrow tract along both sides of the Rio Dulce, and a still smaller tract on the banks of the Salado. Though the soil is sandy, it has great fertility in the neighbourhood of the river, producing plentiful crops of wheat and some good grass. Where it is not cultivated, it is mostly covered with large trees. In the deserts which surround the cultivated tract that species of cactus on which the cochineal insect lives is abundant, and a considerable quantity of cochineal (from 8000 to 10,000 lbs. annually) is sent to Peru and Chile. Some districts have good pasturage. The inhabitants, among whom are many Indians that speak the Quichua language, are industrious, and manufacture *ponchos* (cloaks) and coarse saddle-cloths or blankets. Some soda is extracted on the borders of the Great Salina from the salsola. This country is considered the hottest in South America. Santiago del Estero, on the right bank of the Rio Dulce, has about 4000 inhabitants, and exports cochineal and ponchos to Tucuman and Peru. Matara is a small place on the Rio Salado, where it begins to be navigable.

7. *Tucuman* comprehends the greater part of the slightly-inclined plain which extends from the base of the Sierra de Aconquija towards the Rio Salado, but does not reach its banks, being separated from them by a broad tract of waste land. The Rio Salado divides it from the nomadic tribes of the Gran Chaco, the Rio Tala from the state of Salta, and the Sierra de Aconquija from that of Catamarca. It unites great fertility of soil with abundance of water, and is the best cultivated state in the Argentine republic. Rice, wheat, maize, and tobacco are raised and exported. The declivities of the mountains contain timber and excellent grass. The cattle are larger than in any other state. In the mountains gold, silver, copper, and lead are said to exist, but no mines are worked at present. The capital, San Miguel de Tucuman, which stands on an elevated plain, has a hot but dry and salubrious climate. The inhabitants exceed 8000. It carries on a considerable trade in cattle and mules; the latter are sent to Bolivia.

8. *Salta* occupies the northern portion of the territories that belong to the Argentine Republic, and has every variety of soil and climate. On the east, where it borders on the Gran Chaco, the boundary-line has not been fixed. On the north it borders on the departments of Tarija and Potosi, in the republic of Bolivia, and is divided from them by the desert table-land of Yavi and the range called Abra de Cortaderas. It comprehends the Despoblado, whose climate resembles that of Siberia; the valley of the Guachipas, which in climate and productions represents Europe: and the Plain of Salta and the valleys of the Rio de Jujuy and Lavayan, which in both respects resemble the West Indies. Its commercial products consist of tobacco, sugar, and cotton. A great number of mules, which are bought in the southern provinces in a very lean state, acquire strength in the rich pastures of Salta, and are sent to Peru and Bolivia, and this traffic is one of the principal sources of wealth to the inhabitants. The mountains contain gold, silver, copper, and other metals, but these mines are little worked. Salta, the capital, is situated in a plain about ten miles wide and forty long. The streets are regular, but narrow, and the houses of brick, but not large. In the centre of the square are the government-house, the cathedral, and several public buildings. The population is estimated at 8000 or 9000. The commerce is not considerable. Jujuy is built in an extensive basin, surrounded by high mountains, on the banks of the Rio de Jujuy, an affluent of the Lavayen: it contains about 4000 inhabitants, and has some traffic, as the carriage-road leading to Bolivia terminates at this place, and the goods must be transported farther north on mules. At Jujuy begins one of the most extraordinary mountain-passes in the world. A narrow valley extends from the town to the summit of the range called Abra de Cortaderas, a distance of 90 miles by the road. The highest summit of this road appears to have an elevation of between 11,000 and 12,000 feet. Oran is a small town on the Rio de Tarija, about 30 miles above its junction with the Rio Lavayen. At this place the river navigation is said to commence.

Some years ago the inhabitants of Jujuy made an attempt to establish a government in their town, independent of the provincial government of Salta. We do not know how far this attempt has succeeded.

9. *Catamarca* comprehends the country between the mountain-ranges of the Sierra of Aconquija and Ambato on the east, and the Andes on the west, which is very little known. It consists of some valleys, running between mountain-ranges south-east and north-west, and terminating, at their southern extremity, on the borders of the Gran Salina, being thus separated from the other inhabited countries by high mountains and deserts. The rivers which water these valleys are lost in the Gran Salina. The climate is sultry, and especially so when the south winds blow, which come over the desert. It appears that maize and wheat are raised to a considerable extent, but cannot be exported over the mountains. It sends only cotton and red pepper to the adjacent countries, the latter chiefly to Buenos Ayres, where it is extensively used. The present capital is Catamarca, whose population is stated to be 4000. The first capital was called London, being founded at the time when Philip II. of Spain married Queen Mary of England. It is not known if that place is still inhabited.

10. *Rioja* comprehends the country between the Gran Salina and the Andes, from 28° to 31° S. lat., and consists of a narrow strip of cultivable land along the eastern base of the Sierra Velasco, and the two valleys of Famatina and Guandacol, to which a pastoral tract extending round the southern extremity of the Sierra Velasco must be added. The silver-mines of Famatina are very rich, but being situated above the line of vegetation, they are worked on a small scale. Only the northern districts of the country east of the Sierra Famatina are fit for agriculture. The state is divided into four departments, of which that lying east of the Sierra Velasco is called Arauco, and produces wheat, maize, and cotton. Its principal wealth is its vineyards. About 7000 barrels of wine, of sixteen gallons each, and 100 of brandy, are annually made, nearly the whole of which is exported. The capital, which is also that of the whole state, contains between 3000 and 4000 inhabitants, and has many substantial houses. The department of Famatina, which is included between the Sierra Velasco and Sierra Famatina, contains rich orchards in its northern districts, and exports some wine. The department of Guandacol lies between the Sierra Famatina and the Andes, and produces very rich crops of wheat. It is inhabited by aborigines, who hunt the vicuña in the adjacent mountains. The wool of the vicuña is the only article of export. The fourth department is called the Llanos, which is a desert plain, containing a great number of grassy oases, on which there are cattle-farms. It is stated that 16,000 head of cattle are exported annually.

11. *San Juan* extends along the eastern declivity of the Andes, from 30° 30′ to 32° S. lat., comprehending the northern part of the Vale of Uspallata and a large portion of the plain which separates the Paramilla range from the mountains of Cordova. The Vale of Uspallata is barren and nearly uncultivated. The soil of the plain consists of sand, and is without grass, but covered with stunted prickly trees of the mimosa kind. It is quite barren, and produces no kind of grain or vegetables, except where it is irrigated

by the sweet water of the Rio de San Juan and some of its minor affluents. This irrigation renders the land exceedingly fertile; without any other manure, they produce most plentiful crops of wheat and Indian corn. The ordinary crops of wheat are fifty for one, in better lands eighty or a hundred for one, and in a few places it is said to be two hundred and even two hundred and forty. The distance from a market and the difficulties attendant on the transport of heavy goods through desert plains, greatly diminish the value of this fertility. But as fruit-trees, especially vines, succeed very well in this soil, wines and brandies are exported to a considerable amount. This country contains the chlamyphorus. [CHLAMYPHORUS.] In the northern district, called Jachal, there are some gold-mines, whose produce is not great. The capital, S. Juan, on the banks of the Rio de S. Juan, is stated to have a population of 8000. It is the entrepôt of the wines and brandies which are sent to the other provinces.

12. *Mendoza* extends from 32° S. lat. to the old boundary-line (35° S. lat.), along the foot of the Andes, and includes the southern part of the Vale of Uspallata and the whole of that of Tunuyan. It contains the volcanoes of Aconcagua, Maypu, Rancagua, and Peteroa, and the Andes are here crossed by the most frequented roads which lead over the mountain-passes of Uspallata, Portillo, and Las Damas. The valleys of Uspallata and Tunuyan are barren and nearly uninhabited. The plain which stretches from the Andes eastward has a sandy soil and does not produce grain, nor even grass, without irrigation, but when irrigated it yields abundant crops of wheat, Indian-corn, and lucerne; the lucerne may be cut fourteen times in a year. Rain and dew are very rare, except in the southern districts on the banks of the Rio Diamante, where the rains are so abundant that corn may be raised without artificial irrigation, but agricultural settlements have only been established lately in this district. The vineyards and plantations of fruit-trees are extensive. The produce of this country is partly sent to the states farther east, and partly to Chile, as the following table shows:—

Exports of the Produce of the State of Mendoza, in 1827.

Where sent to,	Brandy.		Wine.		Corn & Flour.	Hides.	Soap.	Tallow.
	Pipes.	Loads.[*]	Pipes.	Loads.	Loads.	No.	Loads.	Loads.
Buenos Ayres	336	2144	290	3120	1098	670	..	..
San Luis . .	..	70	..	488	1634	..	60	..
Cordova . .	..	95	..	355	125	..	..	..
Santa Fé . .	..	81	..	172	469	..	..	..
Chile . . .	..	12	..	..	..	8700	571	88

In this table the dried fruits are omitted, as well as the mules. The dried fruits consist of figs, peaches, apples, nuts, and olives. They go mostly to Chile, whither also from 300 to 400 mules are annually sent. Mendoza, the capital of the state and the centre of its commerce, is situated at the foot of the Andes, 4891 feet above the level of the Atlantic, in a country irrigated by numerous cuts from the Rio de Mendoza. It is a neat and pleasant town; the houses are only one story high, and have porticos. The climate is dry and noted for its salubrity. The population may amount to 12,000. San Martin, or Villa-nueva, west of Mendoza, is a thriving place, with 2000 inhabitants.

13. *San Luis* comprehends that immense tract of country which extends between the state of Mendoza on the west and that of Cordova on the east. Its north-western part runs northward to the boundary of Rioja and the border of the Great Salina, and it reaches southward to the old boundary-line (35° S. lat.). No part of it possesses any considerable degree of fertility. The greatest number of the widely-scattered and isolated settlements, consisting mostly of cattle-farms, occur along the road leading from Buenos Ayres to Mendoza, in the hilly country, where tracts of grassy land alternate with ridges of hills and sandy deserts overgrown with mimosas. As the grass is coarse and long, the pastures are indifferent; still cattle, horses, mules, and sheep are abundant, and are exported to a small amount, together with some wool. The corn and maize which are raised are not sufficient for the consumption of the scanty population. The country between the Sierra de Cordova on one side, and Mendoza and San Juan on the other, is still worse. As no fresh-water stream runs through it, it cannot be irrigated, and, with the exception of a few spots, is a complete desert. San Luis de la Punta, the capital, is a poor village-like town, with 1500 inhabitants.
